On the other hand, the severe skin symptoms of egg white induced biotin deficiency can be produced much more rapidly when fat replaces the carbohydrate.[22] This cannot be considered as a direct adverse effect of fat because in this case the skin symptom evidences of the biotin deficiency appear more quickly, probably because the rat's growth rate is better on the high fat diet and hence the stores of the vitamin are exhausted sooner.

The recent demonstration [23] that a nicotinic acid deficiency in the rat is more readily produced on a low fat diet and that 30 per cent of fat in the diet tends to counteract this deficiency is another example of the vitamin sparing action of fat.

It was observed early in the work on vitamin B_6 that the acrodynia symptoms associated with this deficiency were more apparent when fat was omitted from the diet. This observation was more particularly related to the presence of certain fatty acids in the diet, especially linoleic acid.

The relationship between high fat diets and the requirement of choline and labile methyl groups is indicated by the fact that a simultaneous deficiency of these two factors in high fat diets results in more rapid fatty infiltration and necrosis of the liver, with frequent findings of hemorrhagic degeneration of the kidney.

It is understandable that the numerous favorable effects of high fat diets should be interpreted from the point of view of the known role of certain of the B complex vitamins involved in carbohydrate metabolism, but to assume that these vitamins are not as important in the metabolism of fat may be merely a reflection of our ignorance of the biochemical transformations involved in the ultimate breakdown of fat.

A fresh point of view concerning the value of fat in the diet is based on the finding of Forbes and his associates [24] that, on a mixed diet containing fat, animals have extra calories for work, growth or storage. These extra calories are not available when fat is omitted from the diet even though an isocaloric mixture of carbohydrate and protein is supplied. Fat apparently confers efficiency of utilization of food energy on both growing and mature rats. The observed retention of nitrogen as tissue protein was over 10 per cent greater on a 30 per cent than on a 2 per cent fat diet. In other words, the energy cost of metabolizing diets providing constant protein intake decreased with increasing ratio of fat to carbohydrate. Deuel [25] has recently concluded that the favorable effect of diets containing fat is due to several factors: (*a*) the greater intake in terms of energy values of diets containing fat and (*b*) greater efficiency of utilization.

The value of dietary fat in the utilization of certain carbohydrates is indicated from the work of Schantz and his associates,[26] who showed that the 3 or 4 per cent of fat naturally present in milk is necessary if the animal is to make complete utilization of the lactose or, more specifically, of galactose. Geyer and his associates,[27] in more recent experiments on this subject, conclude that (*a*) fat in some way influences galactose utilization, (*b*) galactose utilization is appreciably decreased as the percentage in the diet is increased and (*c*) added glucose does not lower galactose excretion as does fat.

Since approximately 50 per cent of the calories of whole milk are derived from fat, it is obvious that the use of milk as the sole source of calories will not result in physiologic embarrassment due to the failure of galactose utilization (except in certain rare cases). Nature would indeed be cruel to permit anything but this condition to exist, since infants in particular obtain nearly all their calories from milk.

Handler,[28] writing on this subject, considers that there is a biochemical defect which underlies the failure of lactose (galactose) utilization and indicates that this is due to an impairment of normal glucose metabolism, although no definite statement is given as to the nature of this disturbance.

One must consider that at high levels of galactose ingestion the ability of the organism to convert galactose to glucose is rapidly exceeded, in which event the excess is excreted. The only "biochemical defect" then according to this interpretation would be one of overdosage.

Whether or not fat or any of the intermediates of fat metabolism exert a biochemical note in the reactions involved in the conversion of galactose to glucose to glycogen can be ascertained only after additional research.

CARBOHYDRATE: RELATIONSHIPS TO VITAMIN REQUIREMENTS

As a readily available and most economical source of energy, carbohydrate is of primary importance in nutrition. About 50 or 60 per cent of the calories of the "average diet" are derived from carbohydrate, although wide deviations from this amount are possible, witness the low carbohydrate intake of the Eskimo and the reduced intake of the person with diabetes. Using milk as a nutritional standard again, it can be seen that in this food carbohydrate comprises only about 30 per cent of the total calories. McCollum [29] states that "the minimum amount of carbohydrate necessary for maintenance of life and the prevention of ketosis is from 10 to 15 per cent of the total energy requirement." Species variation may modify these figures to some extent.

Aside from observations, such as the different absorption rates of hexose sugars,[30] the general unavailability of pentoses and cellulose for man, and the aforementioned findings concerning galactose and lactose, very little information is available concerning the comparative nutritional qualities of the several types of carbohydrate which man can utilize.

It is indeed a fortuitous economic fact that ruminants, such as the cow, have a type of digestive system which permits utilization of a substantial portion of dietary cellulose. This fact is a result of the favorable action of cellulose digesting organisms in the rumen which are capable of breaking down cellulose to available hexoses.

This particular mechanism of bacterial action is not present in the human digestive tract, but another type of bacterial synthesis can undoubtedly act in a beneficial manner for man. The extent to which a favorable bacterial synthetic mechanism can assist man in supplying certain factors may depend very importantly on the type of carbohydrate employed in the diet, if the experiments with animals can serve as a guide. Fridericia [31] was the first to observe that animals can grow satisfactorily on certain diets deficient in the "B vitamin." This condition, known as refection, can be readily produced by giving diets which contain raw potato starch as the carbohydrate. Cooked potato starch on the other hand does not cause refection. These observations have been confirmed by numerous workers, and extended applications of the phenomenon have been made.

The fact that the growth and appearance of experimental animals on diets deficient in certain members of the B complex vitamins can vary considerably, depending on the type of carbohydrate used, indicates that there are decided differences in the nutritional value of carbohydrates not reflected by their similar energy values.

Results common to all the experiments that will be cited can be summarized by saying that, regardless of which vitamin was investigated, its requirement was reduced in all cases when relatively insoluble carbohydrates, such as dextrin or starch, were used in the diet. Lactose has also given similar results in many cases, although not so accentuated, and surprisingly enough in some cases diets containing glucose have favorably influenced the vitamin requirement. In all cases when sucrose was the dietary carbohydrate of choice, the vitamin requirement was highest. One might place the carbohydrates in the following decreasing order in their favorable effect on vitamin requirement: dextrin, starch, lactose, glucose, sucrose, although this varies with different vitamins.

It seems reasonable to the proponents of the mechanism of intestinal synthesis that certain carbohydrates, owing to their slower breakdown and absorption from the intestinal tract, provide a suitable substrate for the development of a type of bacterial flora which may contribute significant quantities of vitamins to the host. Mannering [20] states for example that, "when the riboflavin intake is suboptimal, rats receiving a diet rich in dextrin or corn starch show greater weight increases than do animals receiving diets characterized by their content of sucrose, cellulose, lactose or lard. Lactose is not entirely without effect in this respect."

In a recent study Krehl and Carvalho [22] showed that the use of dextrin in pantothenic acid deficient diets greatly improved rat growth. This favorable synthesis of pantothenic acid could be correlated with higher levels of this vitamin in cecal contents, liver and muscle tissue and could be further related to much less hypertrophy and hemorrhage of the adrenal and better protection against involution of the thymus in comparison with deficient animals which received sucrose as the carbohydrate. Likewise the onset of symptoms of egg white induced biotin deficiency were delayed when dextrin was used as the carbohydrate instead of sucrose, despite the fact that the dextrin fed rats grew better, which would tend to increase the demand for biotin.

Good evidence is available [32] to support the idea that pyridoxine is synthesized by intestinal bacteria when the sucrose of the diet is replaced by dextrin. That this mechanism may be available to man may in part explain the limited evidence for pyridoxine deficiency in this species.

In a study on the effect of diet on the response of chicks to folic acid, Luckey and his associates [33] report that the response to folic acid was least with high fat diets or with diets containing glucose, sucrose or starch as the sole carbohydrate. The best response to the

vitamin was obtained with high protein, low fat diets or with diets containing corn meal or dextrin. It is difficult to ascertain why in this case differences between corn starch and corn meal and dextrin were observed. A possible explanation might be due to the rather undesirable physical aspects of diets high in corn starch. It seems that several interrelating factors may be involved in influencing the effect of diet on the folic acid requirement of the chick.

Such a complexity between diet composition and vitamin requirement is well demonstrated in the interesting series of experiments [34] which have established certain conditions under which a nicotinic acid deficiency can be induced in the rat, an animal which had normally been considered not to require a dietary source of this vitamin.

It was first shown that if 40 parts of the sucrose of a "synthetic ration" are replaced with corn grits, the nicotinic acid requirement of the growing dog is increased from about 0.3 mg. per kilogram of body weight to about 1 mg., despite the fact that corn grits contribute some nicotinic acid to the diet. When this study was extended to the rat by replacing 40 per cent of a synthetic diet with corn or corn grits, which reduced the casein level of the corn supplemented diet to 9 per cent, a retardation of growth was demonstrated. This growth depression could be completely counteracted by the further addition of nicotinic acid to the diet, again despite the fact that in these experiments the corn and corn grits contributed 0.8 and 0.4 mg. of nicotinic acid per hundred grams of diet, respectively.

It was recognized in this work that rat growth on a 9 per cent casein synthetic diet deficient in nicotinic acid is not optimum and generally is improved by the addition to the diet of amounts of nicotinic acid up to 1 mg. per hundred grams. If by this addition of nicotinic acid growth is improved, why does not a similar amount of nicotinic acid as represented in corn grits, for example, likewise improve growth, particularly when one considers that the total protein and type of carbohydrate contributed by the corn should have some supplementary action to the diet? Actually a growth depression can be observed.

Although the foregoing observations have been confirmed in other laboratories, a criticism [35] has been made of these findings on the basis that the growth of rats is poor on a 9 per cent casein diet with or without the inclusion of corn and therefore corn has no "specific deleterious effect." In fact, in this particular experiment the growth results obtained on the basal 9 per cent casein diet were so poor (less than 3 Gm. per week for eight weeks) as to obviate a very fair comparison. It is interesting to note though that in these experiments the addition of crystalline nicotinic acid also evoked a better growth response than did corn alone, which again is difficult to explain since in some of these cases at least nearly as much nicotinic acid must have been contained in the added corn as was added in crystalline form. Whether or not corn has a "specific deleterious action" quite largely depends on extenuating circumstances. If, under defined conditions, one compares corn with certain other cereal grains such as polished rice, which closely resembles corn in its nicotinic acid and tryptophan content (to be discussed) one finds corn decidedly inferior, using the growth of young rats as a criterion. Further evidence for the observed action of corn rations is indicated by the demonstration that corn contains a pellagragenic agent which can be extracted and prepared in fairly high concentration. This "pellagragenic material" from corn when fed to mice produced a manifest growth depression. Interestingly, corn alone does not have this effect in mice.[36]

PROTEINS AND AMINO ACIDS IN NUTRITIONAL IMBALANCE

In studying the effect of corn on the growth of rats it was soon learned that, when the casein level of the diet was increased, good growth resulted whether or not corn was used in the diet. This seemed to indicate that in conjunction with the nicotinic acid deficiency a concomitant amino acid deficiency might be involved. Since corn is notably deficient in tryptophan, this amino acid was added to the corn supplemented ration and, surprisingly enough, proved to be as effective as nicotinic acid in promoting growth. This fact indicated then an interrelationship between a vitamin, nicotinic acid, and an amino acid, tryptophan. As already stated, rather specific conditions are needed for the production of this nicotinic acid deficiency in the rat. When, for example, dextrin, corn starch itself or even glucose is used as the dietary carbohydrate in place of sucrose there is little growth inhibition from corn. A low general level of vitamins accentuated the action of corn rations in retarding rat growth. The favorable effect of a carbohydrate such as dextrin has been interpreted as being due to the establishment of an intestinal flora which augments nicotinic acid synthesis. Since, as has been mentioned, high levels of dietary fat tend to reduce the nicotinic acid requirement of the rat,[23] the inclusion of 30 per cent of fat in the diet largely but not entirely eliminates the growth retardation induced by corn.[35] Whether this effect can be likewise observed in man, whose requirement for nicotinic acid is probably much higher than that of the rat, must be questioned, particularly in view of the fact that pellagra producing diets in the South generally contain liberal amounts of fat from "sowbelly."

A recent extension of the effect of corn rations on the nicotinic acid requirement has been made with the pig [37] in which it was observed that the use of corn as a major part of the ration resulted in a nicotinic acid deficiency even though the percentage of dietary protein was relatively high. "The supplementation of the low protein corn rations with tryptophan produced animals whose external appearance was normal in every respect." This supplementation also resulted in increased efficiency of food utilization.

Perhaps more interesting than the effect of corn supplemented rations on the dietary nicotinic acid-tryptophan requirement of the rat are the observations [38] that a completely analogous syndrome can be produced by adding tryptophan free proteins or acid hydrolysates of protein (tryptophan free) to basal rations which contain 9 per cent casein and no nicotinic acid. For example, a protein such as zein, the chief protein from corn, when added to such a ration at a level of 3 per cent, produces a nicotinic acid deficiency in the rat which can be completely counteracted by either tryptophan or nicotinic acid. The addition of gelatin at levels of 3 or 6 per cent produces a similar result.

What are the peculiarities of the amino acid mixture in acid hydrolysates of protein or the amino acid makeup of tryptophan free proteins that induce such effect? No precise answer can be given on this point although it has been shown that the amino acid aminoacetic acid (glycine) is one (of perhaps many) which is capable of inducing an increased nicotinic acid requirement in the rat. Evidence is available,[39] however, to show that this growth inhibiting effect due to amino acids is not specific for any one particular amino acid but may in fact be produced by a mixture of synthetic amino acids equivalent to 2 per cent of an acid hydrolysate of casein. It is possible that the growth inhibition may be due to alterations in the intestinal flora, since the effect of aminoacetic acid is eliminated when dextrin is used as the carbohydrate in place of sucrose. Of course a mechanism involving tissue synthesis of nicotinic acid might very well be involved, or perhaps both of these mechanisms are concerned in this complex interrelationship between nicotinic acid and tryptophan. Only additional research can answer these questions.

That other species are susceptible to the effects described can be seen from work with chicks [40] in which it was shown that the nicotinic acid requirement of the chick was influenced by the kind and amount of protein used in the ration. Gelatin produced unfavorable growth results when nicotinic acid was omitted from the diet, and this growth depression could be completely counteracted with either tryptophan or nicotinic acid. When combinations of the amino acids arginine, aminoacetic acid and alanine were used, nicotinic acid deficiency symptoms were also produced.

No definite evidence is as yet available which completely elucidates the mechanism of the niacin-tryptophan relationship. As stated, certain evidence strongly supports the idea that the intestinal flora may contribute importantly to nicotinic acid synthesis. Another line of evidence has been advanced which supports the contention that tryptophan may serve as a metabolic precursor of nicotinic acid. This is based on the finding [41] that the excretion of N^1-methylnicotinamide, the chief urinary excretory product of nicotinic acid metabolism, is much increased following the administration of l(-) or dl tryptophan to the rat. Such a hypothesis is certainly attractive, and the correlation between N^1-methylnicotinamide excretion and tryptophan ingestion has been extended to a number of species, including man. Work with Neurospora mutants however has so far failed to establish any direct mechanism or metabolic pathway from tryptophan to nicotinic acid,[42] although a relationship between this vitamin and tryptophan similar to the rat and other species is well established for certain of these mutants. This of course does not prove that a direct synthesis of nicotinic acid from tryptophan does not exist.

The recent observation [43] that pyridoxine deficient animals excrete less N^1-methylnicotinamide after the administration of tryptophan may help to throw some light on the indicated metabolic conversion of tryptophan to nicotinic acid and at least "indicates that the normal formation of xanthurenic acid in B_6 deficiency is not responsible for the impaired tryptophan to nicotinic acid transformation." This observation might in a sense be considered an extension of the earlier study by Singal and his associates, who observed an increased excretion of N^1-methylnicotinamide as a result of administering pyridoxine to normal and nicotinic acid deficient dogs.

It might be pointed out that, since niacin may exert a tryptophan sparing action, possibly because of its favorable influence on tryptophan utilization,[44] the administration of tryptophan might correspondingly spare or reduce the metabolic need for the vitamin so that the excess not needed for other purposes is then methylated and excreted.

Aside from the theoretical aspects of why both tryptophan and nicotinic acid have similar growth promoting effects, it is gratifying to note that recent experiments with human beings [45] indicate that "tryptophan may be an important precursor of nicotinic acid in the human as well as the rat and may explain the antipellagragenic activity of certain foods such as milk which are low in nicotinic acid but rich in good protein." It might be noted that here no consideration is given to the known favorable effect of milk on the synthetic mechanism of the bacterial flora in experimental animals at least.

The relationship between proteins or amino acids and vitamins is also indicated in the evident importance of pyridoxine in the metabolism of amino acids. The vitamin B_6 group of vitamins has been shown to be important in two fundamental reactions involving amino acids: (*a*) catalyzing transamination [46] and (*b*) catalyzing the decarboxylation of certain amino acids.[47]

A specific role of pyridoxine seems to be involved in tryptophan metabolism,[48] in which case the administration of 1(-)tryptophan to pyridoxine deficient rats results in the excretion of xanthurenic acid rather than kynurenic acid, the normal end product of tryptophan metabolism. Kynurenic acid and more interestingly d(+) tryptophan do not lead to xanthurenic acid excretion in B_6 deficiency; xanthurenic acid passes through the pyridoxine deficient rat unchanged.

That the level of dietary protein is important in determining the pyridoxine requirement is evident from the observation [49] that a diet containing a 60 per cent level of casein produced much earlier death in mice than one in which the protein level was 10 per cent. "Although pyridoxine restored growth and minimized the excretion of chromogen on both diets, about three times as much pyridoxine was required on 60 per cent of casein as when 20 per cent was fed."

Because of the ever increasing interest in the use of synthetic amino acids in nutritional studies, some mention must be made of certain recent experiments made with these materials. The long chain of research on the qualitative and quantitative amino acid requirement stemming mostly from the laboratory of Rose has culminated in the successful use of diets which can be entirely characterized in regard to their amino acid makeup. As might be expected with such relatively short time experience with amino acids there is no complete agreement as to the number or relative amounts of the so-called "essential" amino acids required by the various species studied. Clarification of these disagreements should come rapidly as a result of the intensive research in this field. A generalization that might be made concerning amino acids and their application in nutritional studies can be gleaned from the observation [50] that rats fed a mixture of amino acids gained weight rapidly and usually exhibited weight gains in ten days as great as on diets containing an isonitrogenous quantity of casein. The omission of any of the essential amino acids from the diet resulted in a prompt loss in appetite followed by a weight loss. It must be noted, however, that these experiments were conducted with adult rats, and evidence is available [51] which shows that the young growing rat does not do as well on mixtures of amino acids as on casein in equivalent amounts. Further evidence of this nature is observed with mice, and the factor which induces better growth under these conditions has been designated strepogenin,[52] which is a peptide-like material found in certain intact proteins or incomplete protein hydrolysates. Whether this factor has practical significance in human nutrition is difficult to ascertain. It is known, however, that properly prepared mixtures of the crystalline amino acids are adequate for the protein nitrogen needs and definite weight gain of patients over "long" periods of time. Given parenterally as the sole source of protein nitrogen intake, these amino acids are adequate for nitrogen balance in human patients.[53] In these same experiments no toxicity to the unnatural forms of seven essential amino acids could be demonstrated. Although the amino acids were generally well tolerated when given parenterally, phenylalanine had a definitely limited effect on tolerance. It has been shown however [54] that mixtures of natural amino acids can be given to dogs at a much higher intravenous rate without inducing vomiting than can similar mixtures containing racemic amino acids. In these experiments aminoacetic acid increased the dog's tolerance to the infusion of certain of the mixtures containing racemic amino acids.

Lack of agreement is evident concerning the undesirable effects of the unnatural forms of certain amino acids for rat growth. Factors such as the relative amount of the respective amino acid used and the type of carbohydrate employed in the diet may explain a large part of the differences observed. Most of the evidence supports the contention that the unnatural forms of the essential amino acids at least do not significantly impair the animal's performance. It has been shown that dl serine, unlike the natural isomer, produces proteinuria, kidney and liver damage and high mortality in rats.[55] Interestingly enough, the administration of ample amounts of B vitamins substantially reduced these effects. Of the vitamins tested, pyridoxine proved most effective in its protective action against dl serine.

Another point of disagreement has arisen as a result of the several studies on the relative lipotropic efficacy of methionine when fed as the free amino acid and as a constituent of an intact dietary protein. A reasonable explanation for the conflicting conclusions, and well illustrative of the present theme that many interrelated factors may alter the dietary requirement, is offered in the finding that essential amino acids have a definite effect on the lipotropic efficacy of methionine.[56] "No significant difference was noted in the lipotropic effect exerted by methionine when fed as the free amino acid or in casein, provided the essential amino acids were approximately equalized in the two diets."

The great interest in amino acids has revived in large measure the older problem concerning the biologic value of proteins. The studies on this problem may in general be summarized by the observation [57] that "the comparison of the chemical and biologic methods supports the hypothesis that the biologic value of a protein is due to its content of essential amino acid and is limited by the one essential amino acid which is present in the least amount relative to body requirements." One of course should add that, as indicated earlier, other components of the diet may play an important role in determining the biologic value of certain proteins. Then too, it is now recognized that there are certain as yet unknown factor(s) accompanying some proteins which have definite effects on such vital physiologic processes as growth, reproduction and lactation in experimental animals.

That certain amino acids may play more or less specific roles in determining the biologic value of a protein is indicated in the observed effectiveness of methionine in sparing nitrogen. It has been shown for example [58] that methionine added to diets which contain egg white and casein respectively spared nitrogen; this sparing action was more obvious with the latter protein. The sparing action is apparently produced through a reduction in the excretion of urea nitrogen.

VITAMINS AND VITAMIN INTERRELATIONSHIPS

Despite their great physiologic activity in small amounts, vitamins as such are relatively "nontoxic" at least in several multiples of even large therapeutic doses, and an excessive intake of a vitamin results for the most part in its excretion in the urine unchanged. This is in sharp contrast to most "drugs" and hence more or less places the vitamins in a separate category, at least from the aforementioned standpoints.

It has been shown though that, in the case of the B complex vitamins, treatment with the single vitamin indicated by the predominant signs in a patient with a deficiency disease may result in the precipitation of severe manifestations of other deficiencies. This would argue in favor of the rational use of B complex mixtures in the treatment of deficiency diseases, since in most cases a complex deficiency is present, though not always readily apparent by the available clinical methods.

Examples of some of the more obvious interrelationships of vitamins (though by no means completely understood) are (*a*) the vitamin A activity of certain carotenoid pigments, (*b*) the antirachitic action of the several vitamin D compounds and (*c*) the effectiveness of the several compounds having vitamin K activity in promoting blood coagulation. Other examples in the B complex group of vitamins are seen in the similarity of activity exhibited by the B_6 group (pyridoxine, pyridoxal and pyridoxamine) and the effectiveness of niacin, niacinamide and nikethamide (di-ethyl nicotinamide) in pellagra.

It is understood, however, that these various compounds with similar physiologic activity are active because certain essential and fundamental similarities exist in their chemical structure

Illustrative of another kind of vitamin interrelationship (many of which exist and probably more will be discovered) is the observation [59] that the utilization of tocopherols in patients suffering from muscle dystrophy was enhanced by the simultaneous injection of inositol. It has been suggested that tocopherol forms a condensation product with inositol in the gastrointestinal tract and that the inherent defect in muscular dystrophy is in a deficiency of this condensation product.

Other work with alpha-tocopherol [60] indicates that it improves the effectiveness of suboptimal quantities of linoleic acid in preventing or curing the essential fatty acid deficiency syndrome in the rat. More interesting, and possibly of some practical importance, is the recent observation [61] that dietary supplementation with alpha-tocopherol favorably influences milk-fat concentration and total "4 per cent milk" production in the dairy cow, although simultaneous use of vitamin A supplementation negates this effect of tocopherol. Vitamin A supplementation alone increased the vitamin A content of the milk "at the partial expense of the carotene content," but the combined supplementation of vitamins E and A "allowed the A content of the milk to rise without a pronounced fall of carotene."

Another practical relationship of vitamins is demonstrated in the finding that, although cattle are able to synthesize vitamin C to meet their requirements, the amount of synthesis is greatly reduced in vitamin A deficiency. In such cases the injection of vitamin C has had a beneficial effect on sterility

Turning to the B vitamins, it has been shown in rats [62] that thiamine and pantothenic acid influence the mobilization of riboflavin in the liver, and during the mobilization a portion of the transported riboflavin is excreted in the urine.

It has also been observed that on diets which contain insoluble sulfonamides· the pantothenic acid utilization, as reflected by increased concentration of this vitamin in the liver of pantothenic acid deficient rats, is favorably influenced by the inclusion of biotin and folic acid in the ration.[63]

Folic acid also seems to play an important role [64] in improving the absorption of vitamin A and carotene in sprue patients. This action is probably due to the influence of folic acid in favoring a normal functioning of the gastrointestinal tract.

The foregoing examples are indications only of the multiplicity of complex relationships which may exist between vitamins and between vitamins and the other nutrients. The mechanisms involved in the many relationships can be clarified only by intensive research.

In a consideration of the effect of diet on the requirement of specific nutrients one must also consider factors which influence availability of vitamins. To illustrate this type of imbalance, it has been shown for example that certain fish products which are consumed in the raw state by man contain the enzyme thiaminase, which may appreciably destroy thiamine in the gastrointestinal tract.[65] This type of action is distinguished from the earlier mentioned "toxicants" and "inhibitors" in that here a substance is present in food that destroys another substance that is required by the host although the destructive agent is not harmful to the host directly. Obviously, reason must be exercised in estimating the practical significance of such an observation, but the fact that this condition does exist is worthy of consideration.

Another of the important factors that affect the physiologic availability of a vitamin is apparent from the finding that of the thiamine present in live compressed yeast only a small portion is actually available to the host.[66]

That there are many other extrinsic factors which may favorably or adversely affect the animal's requirement for nutritive factors is clear when one considers the general differences between species and the strain variations within species. To cite such a species variation, one may point to the important difference between the rat and the chick in regard to their respective abilities to synthesize choline, the rat having a much more efficient mechanism for this synthesis than the chick. Of course the chick's requirement for the "micronutrients" in general seems to be much more critical than the rat's. This holds true also for the guinea pig. Strain variations in certain vitamin requirements are evident in at least the rat and the mouse.

The influence of the interrelationship between hormones and dietary constituents is certainly evident, and this whole field of investigation is advancing with great rapidity.

Although the factors involved in determining what kind and how much of a particular nutrient is required for every normal physiologic function through the entire life cycle of the organism are complex, it must be remembered that what has so far been learned about nutrient requirements still serves as a useful and practical tool which may be further used in elucidating some of the more complex problems.

THE TREATMENT OF ARTHRITIS

In few other fields of medicine is there less exact knowledge of definition, causes or methods of treatment than in arthritis, commonly called rheumatism. Almost as many classifications are available as there are specialists. Most physicians and the public as well group the entire range of disturbances under the words "rheumatoid conditions." One writer[1] has included all these conditions under the term "rheumatic affections" with the main subheadings "rheumatic fever," "rheumatoid arthritis" (which includes many different forms), "osteoarthritis," "fibrositis" and "gout." The articles on rheumatic conditions in medical periodicals are numerous. In the absence of any scientific statistics, except for rheumatic fever, almost any form of treatment seems to produce about 20 per cent of claimed cures or arrest of cases, 30 per cent of improvement and 50 per cent of failure.

For the relief of symptoms a tremendous armamentarium of therapeutic agents is available; with these the competent therapeutist may play on his case like a composer at the keys of a piano. By the use of drugs, physical therapy, improved nutrition, orthopedic treatment, climatic and spa treatment, functional therapy, psychosomatic medicine and a number of miscellaneous measures, many symptoms may be relieved and often the disease may seem to be fully controlled.

Among the methods especially conspicuous at this time—exclusive of physical therapy, which has had some thousands of years of trial—present interest in treatment involves the well recognized use of the salicylates, gold compounds and various forms of vitamin D in high dosage. Continental authorities report cure or striking improvement in a great majority of their patients treated with gold, but American authors report a little over one half of the cases showing improvement to some degree. The figures are not impressive. The results of treatment with gold preparations, for example, can be duplicated by patients treated with a variety of other methods or simply with general therapy. Furthermore, most American specialists in the field of arthritic conditions have noted severe reactions to the use of preparations of gold, particularly in patients inclined to respond allergically to various medicaments.

The advocates of high dosage vitamin D, including Dreyer and Reed,[2] who introduced the method in 1935, have been unable to present statistical evidence much better than that credited to gold or general therapy. Few records seem to be available of cases of rheumatoid arthritis actually arrested, although well over one half of all the patients in each of the published reports on the use of vitamin D seem to have been improved. Thus Abrams and Bauer[3] stated that the "improvement noted always took place slowly. The beneficial results in all cases were short lived. During the follow-up study, the authors noted that the arthritis gradually became as severe as it had been in the pretreatment period." Some emphasis has been placed on the fact that there are varieties of vitamin D. Most of the recent investigation has involved the use of a proprietary preparation known as activated vaporized sterol ("ertron"). Some studies of small groups of cases such as those reported by Farley, Spierling and Kraines[4] and by Snyder and Squires[5] insist that the product is of definite value in the treatment of arthritis and that its use "is not associated with any more danger than is usually encountered with other accepted forms of therapy if the medication is given under the advice and control of a physician." Notwithstanding this comment, a considerable number of instances are reported in periodical literature in which hypercalcemia, vitamin D intoxication and metastatic calcification have occurred. The toxic manifestations accredited to excess dosage include nausea, anorexia, digestive upsets and nosturia. In most instances tissue calcifications have followed tremendous doses, which were usually self administered over long periods of time and without intervals of rest. There seems to be no doubt that such dosages may stimulate hypercalcemia. Nevertheless, instances of generalized calcification occurred before the use of such preparations. Perhaps combinations of conditions peculiar to the individual may be involved in such instances.

Beckman has included activated vaporized sterol with other preparations which he dismisses by saying, "I do not feel that any of the following at present merits the space that a full discussion of the methods of its employment would require." P. S. Hench[6] has stated that "the majority of experienced rheumatologists regard it ("ertron") as essentially useless."

Bauer and Freyberg[7] expressed their belief that the electrically activated ergosterol appears to be less toxic than vitamin D in other forms. Magnuson, McElvenny and Logan[8] noted intolerance to the medication in 26 of 180 patients treated by a combination of orthopedic and physical methods with electrically activated, heat-vaporized ergosterol for an average period of about eight months. They recorded 90 per cent of improvement with this regimen and about 8 per cent of complete failure. They did not find that the symptoms of intolerance were related to either hypercalcemia or renal damage.

In the light of the evidence here discussed, the treatment of arthritis would seem to include such well established methods as physical therapy and orthopedic treatment, prescribed as indicated by the nature of the individual case. The use of proper medication for the relief of pain is warranted. All other methods such as the use of vaccines, fever, sulfur, vitamins (including activated vaporized sterol), bee venom, histamine, penicillin and sulfonamide compounds, roentgen radiation and induced jaundice are still in an experimental and unestablished stage, and the weight of evidence points to the belief that most of them are useless.

HYALURONIDASE (THE SPREADING FACTOR) IN HYPODERMOCLYSIS

McClean[1] and Hoffman and Duran-Reynals[2] established the existence in the mammalian testicles of factors which modify the permeability of connective tissue. Later work established the wide distribution in nature of similar factors as well as their enzymic character. The most important sources of "spreading factor" known today are mammalian testes, invasive bacteria, snake venom and leech extracts. As noted in a previous editorial in THE JOURNAL, Chain and Duthie[3] regard the enzyme hyaluronidase and the spreading factor as the same substance. They showed that fairly pure preparations of testicular spreading factor also possess hyaluronidase activity. Hobby and his co-workers have shown that all preparations which contain hyaluronidase also contain the spreading factor. Hyaluronidase was shown to possess a variety of biologic activities such as bacterial invasiveness and fertilization of the mammalian ovum. Thus hyaluronidase not only produces the spreading reaction but also has the activity to decapsulate certain strains of streptococci, to remove the cumulus cells surrounding the ovum of the rabbit and to decrease the viscosity of synovial fluid.

The spreading activity of hyaluronidase, according to McClean and to Duran-Reynals, is due to the removal of a tissue barrier to fluid diffusion thought to be a hyaluronic acid gel present in the ground substance of the connective tissues. Duran-Reynals states that the spreading action is so rapid with optimal enzyme concentrations that the bleb which results following injection is completely flattened within a minute or less. The enzyme produces a qualitatively similar response in subcutaneous tissue, muscle and possibly in most tissues. Sannella[4] suggested that the enzyme might be useful in a number of clinical problems involving fluid and drug administration, among them in the facilitation of hypodermoclysis.

Hechter and his co-workers[5] employed hyaluronidase to facilitate hypodermoclysis. They found that microgram amounts of a preparation of hyaluronidase facilitate the administration and absorption of fluids administered subcutaneously in both man and the experimental animal. The effect of the spreading factor seems to be dependent on the state of the subcutaneous connective tissues. When the connective tissues are loosely organized, the enzyme increases the rate of administration about twofold. Both in guinea pigs and in 2 patients in whom the subcutaneous tissues were well developed, the rate of fluid administration was increased to a much greater extent by the subcutaneous administration of hyaluronidase prior to clysis. The authors obtained direct evidence that hyaluronidase prevents pain due to distention produced by fluid administration in studies with normal adults who were given an intradermal injection of 1 cc. saline solution with and without hyaluronidase. Without enzyme this volume of fluid introduced intracutaneously produced intense pain which persisted for ten to fifteen minutes, while the same volume administered with hyaluronidase did not produce any pain. The authors point out further that the effect of hyaluronidase in facilitating clinical hypodermoclysis is obtained with such small doses of enzyme extract that hypersensitivity to testis protein does not result. The administration to human volunteers of milligram amounts of the enzyme preparation did not produce a toxic reaction aside from a nonspecific transient foreign protein reaction. These reactions did not occur when the dosage was decreased to 200 micrograms. The enzyme hyaluronidase may also be useful for the subcutaneous administration of large amounts of plasma and drugs. In newborn infants the swellings produced by the subcutaneous injections of 30 cc. amounts of plasma with hyaluronidase disappeared within sixty minutes; without enzyme, six to twenty-four hours were required before the swellings disappeared.

THE GENERAL PRACTITIONER'S MEDAL

The announcement by the Board of Trustees of the American Medical Association of the annual bestowal of a medal on a general practitioner for exceptional service to his community has attracted the attention of the nation. Already many nominations have been made by women's clubs, Rotary clubs and other community groups. The editorial from the Providence, R. I., *Journal*, which follows, presents so charmingly the case for the general practitioner that we reprint it gladly in THE JOURNAL:

General Practitioner

News item: On Jan. 7 the American Medical Association will give a gold medal to a general practitioner selected from the country at large.

Dear Medical Ass'n.,

I been hoping you'd do something like this for over 35 years, and I'd like it to be our family doctor, who has been doctoring us ever since we thought the first baby was a tumor.

You probably never heard of him. He's not one of your big men—never invented anything in a medical way except a little spool and darning needle gadget for removing ingrowing hairs, and the only time he go. into your journal, he says, was the time he had a queer fever of his own. But I feel better the minute he comes into the house, for he doesn't come to see a lot of organs, he comes to see ME. He knows me—knows us all—inside and out, warts, scars, disposition, everything. He knows I can't eat tuna fish, that I get flighty with two degrees of fever, and overdo everything from mowing the lawn to drinking beer. And somehow he manages to add all these things up to make me feel like somebody. I don't believe I'd ever be an "interesting case" to him no matter what I got. I'd just be me. That's really something these days. I don't have to call on him often, but I'd be lost without him.

He's a grand all-round man, good story teller, good listener, good friend, a sort of father confessor with the aid of a stethoscope. It's unbelievable the good he's done in our neighborhood. A lot of people owe him money. I'd certainly like to see him get the medal.

Yours sincerely,

Almost Anybody

RECOVERY FROM HEMORRHAGIC SMALLPOX

Hemorrhagic smallpox is the most malignant form. Death may occur before the outbreak of the eruption gives a clue to the nature of the infection. Weeks and McClelland[1] report the case of a patient who recovered. A young sailor on a U. S. Naval ship which had been off the China coast for two months had been permitted to go each week to Shanghai. He felt well when the ship left for Saipan but on the second day at sea there developed a dull bilateral pain at the costovertebral angles and in the flanks which caused him to bend. At this early stage he had frequency of urination and the urine was dark and cloudy. The next day he had chills and a temperature of 104 F. and was put to bed. On the fourth day an erythematous, macular rash appeared on the inner aspect of both thighs and spread to the trunk, arms, lower legs, abdomen, chest, palms, soles and face. Large purpuric extravasations were noted over the buttocks following injections of penicillin. Hemorrhagic extravasations were present in both conjunctivas and scleras. The nose was rimmed with blood crusts, the lips swollen and crusted by hemorrhagic areas. Fresh blood was noted about the anus. Once the patient vomited blood. Some of the vesicles coalesced to form bullous lesions filled with dark hemorrhagic fluid. The patient became delirious. Here obviously was fulminating hemorrhagic smallpox with hemorrhagic pneumonia, bleeding from the intestinal tract and toxic nephritis. The patient was placed in an oxygen tent, given a transfusion of 600 cc. of ideally matched fresh citrated whole blood. Adequate intake and output were maintained by giving 5 per cent dextrose in isotonic sodium chloride solution or distilled water parenterally, to which supplements of vitamins B, C (ascorbic acid) and K were added. Since death in fulminating smallpox is frequently due to streptococcic septicemia and secondary pneumonia, the patient was given 200,000 units of the calcium salt of penicillin dissolved in 2 cc. of isotonic sodium chloride solution every two hours intramuscularly. Little improvement was noted for two days; then bleeding from the rectum and mouth decreased and the erythema began to fade, leaving the skin about the vesicles a dark reddish brown. Cultures of the vesicular fluid and Paul's test were negative. Whole blood transfusions were continued daily. On the fifth hospital day the temperature dropped to 100.2 F., the pulse rate to 90 and the respiratory rate to 24. The patient became rational, the lungs had almost entirely cleared and the bleeding generally seemed under control. On the tenth hospital day, the penicillin dosage was reduced to 100,000 units every two hours and the transfusions were discontinued. The patient became afebrile on the eighteenth hospital day. He had received in all 26,500,000 units of penicillin intramuscularly. He was discharged from the hospital on the forty-seventh day of his illness with the skin completely clear, and he was rapidly regaining the great amount of weight lost. The massive dosage of penicillin given this patient may not have changed the primary course of his disease, but it probably prevented serious secondary infection, as there was not any frank pustulation. This patient had never been successfully vaccinated against smallpox, although attempts at vaccination had been made at 6 and 12 years of age and again on entering the Navy in 1943. While the last attempt had been recorded as an "accelerated reaction," the patient was unable to recall any type of reaction in any of the three attempts at immunization, and he did not have a vaccination scar. The lack of visible response to the attempted vaccination after entering the Navy was no doubt misinterpreted. Every physician should thoroughly understand and be able to properly interpret the different types of reactions to smallpox vaccination. If when this sailor entered the Navy his vaccination had been properly followed up and repeated until a definite response was obtained he probably would not have contracted the disease that nearly took his life.

ORGANIZATION SECTION

Official Notes

THE INTERIM SESSION OF THE AMERICAN MEDICAL ASSOCIATION

After careful investigation of the availability of accommodations for a midwinter (supplemental) session of the American Medical Association in the short time at its disposal, the Board of Trustees selected Cleveland as the place of that session, since the accommodations for meeting places and for sleeping rooms seemed to be adequate and a convenient time seemed to be open. The midwinter session will therefore be held in Cleveland, Jan. 5 to 8, 1948, the first two days being devoted to a session of the House of Delegates and January 7 and 8 to General Scientific Meetings devoted exclusively to the general practitioner.

The Scientific Meetings, the Scientific Exhibit and the Technical Exposition will be housed in the Cleveland Auditorium, but the place of meeting for the House of Delegates has not yet been selected. The Council on Scientific Assembly, in cooperation with the Board of Trustees, will prepare the program for the Scientific Meetings.

Information concerning hotel reservations will be published as soon as arrangements concerning this matter have been completed.

On January 5 and 6, the Council on Industrial Health of the American Medical Association will hold its Eighth Annual Congress on Industrial Health at the Cleveland Auditorium.

Washington Letter

(From a Special Correspondent)

Oct. 2, 1947.

Research on Heart Disease and Hypertension

Extensive research on heart diseases and high blood pressure has been launched by the U. S. Public Health Service, and an estimated million dollars is to be spent on the project during the next year. Two principal research phases of the program are (1) studies financed by the Public Health Service in universities and hospitals and (2) research and surveys to be handled by the service itself and the states. Present work is planned to lay the groundwork for increased heart research. The program includes research on arthritis. Public health officials report that 2,000,000 Americans died of heart and blood-vessel diseases during World War II, while warfare claimed the lives of only 325,000 Americans. The heart and circulatory diseases kill five times as many persons annually in the United States as cancer does, and rheumatic diseases kill more children between 10 and 15 years of age than does any other disease.

Denies White Bread Flour Has Adverse Effect on Human Beings

Paul B. Dunbar, Food and Drug Commissioner, stated that "there is not as yet an iota of evidence of any adverse effect on human beings" from the use of nitrogen trichloride, which has been used for some twenty years to age white flour for commercial use. The Food and Drug Administration and flour manufacturers have been conducting laboratory tests on the use of the so-called "agene process" since Professor Edward Mellanby, English nutritionist, reported in the *British Medical Journal* that in dogs fed on agene-treated flour there developed canine hysteria. These tests are now reported to have shown no ill effects from the process on human subjects "or other animals" than dogs. The process is used to produce in flour physical changes formerly attained by aging.

Legion Commander Denounces American Hospital Association Proposal

James F. O'Neil, national commander, American Legion, described as "selfish and short-sighted" the proposal of the American Hospital Association that Congress freeze Veterans Administration hospital construction funds until the need for more veterans' beds is better established. Mr. O'Neil said that war-disabled veterans have already been penalized by sluggish progress of the Veterans Administration hospital construction program and added that "it is unthinkable that any group should attempt to retard the program at a time when it is getting up real steam." Mr. O'Neil said that the Legion appreciates the problems of private hospitals and is vitally interested in the maintenance of their standards.

Coming Medical Meetings

Conference of State Medical Society Secretaries and Editors, Chicago, A.M.A. Headquarters, Nov. 7-8. Dr. George F. Lull, 535 N. Dearborn St., Chicago 10, Secretary.

American Academy of Neurological Surgery, Colorado Springs, Broadmoor Hotel, Oct. 9-11. Dr. T. C. Erickson, 1300 University Ave., Madison 5, Wis., Secretary.

American Academy of Ophthalmology and Otolaryngology, Chicago, Palmer House, Oct. 12-17. Dr. W. L. Benedict, 102 Second Ave. S.W., Rochester, Minn., Secretary.

American Association of Railway Surgeons, Chicago, Nov. 23-25. Dr. Raymond B. Kepner, 547 West Jackson Boulevard, Chicago 6, Secretary.

American Clinical and Climatological Association, Colorado Springs, Oct. 13-15. Dr. James Bordley III, Johns Hopkins Hospital, Baltimore 5, Secretary.

American Otorhinologic Society for the Advancement of Plastic and Reconstructive Surgery, New York, Nov. 13. Dr. Norman N. Smith, 291 Whitney Ave., New Haven 11, Conn., Secretary.

American Public Health Association, Atlantic City, Oct. 6-10. Dr. Reginald M. Atwater, 1790 Broadway, New York 19, Executive Secretary.

American Society for the Study of Arteriosclerosis, Chicago, Hotel Knickerbocker, Nov. 2-3. Dr. O. J. Pollak, Wilmington General Hospital, Wilmington 14, Delaware, Secretary.

American Society of Clinical Pathologists, Chicago, Drake Hotel, Oct. 28-30. Dr. A. S. Giordano, 531 N. Main St., South Bend, Ind., Secretary.

Association of American Medical Colleges, Sun Valley, Idaho, Oct. 27-29. Dr. Fred C. Zapffe, 5 S. Wabash Ave., Chicago, Secretary.

Association of Military Surgeons of the United States, Boston, Nov. 13-15. Col. James M. Phalen, Army Medical Museum, Washington 25, D. C., Secretary.

Central Neuropsychiatric Association, Galveston, Texas, Oct. 17-18. Dr. William C. Menninger, 3617 W. Sixth Ave., Topeka, Kans., Secretary.

Delaware, Medical Society of, Wilmington, Oct. 13-15. Dr. John F. Hynes, Memorial Hospital, Wilmington, Secretary.

District of Columbia, Medical Society of the, Washington, Hotel Statler, Oct. 6-8. Mr. Theodore Wiprud, 1718 M Street N.W., Washington 6, Secretary.

Indiana State Medical Association, French Lick, Oct. 28-30. Mr. Ray E. Smith, 23 E. Ohio St., Indianapolis 4, Executive Secretary.

Inter-State Postgraduate Medical Association of North America, St. Louis, Public Auditorium, Oct. 14-17. Dr. Tom B. Throckmorton, 406 Sixth Ave., Des Moines, Iowa, Secretary.

Kansas City Southwest Clinical Society, Kansas City, Mo., Municipal Auditorium, Oct. 6-9. Mr. E. Leas Clower, 630 Shukert Bldg., Kansas City 6, Executive Secretary.

New England Postgraduate Assembly, Boston, Copley-Plaza Hotel, Oct. 29-31. Dr. Leroy E. Parkins, 8 Fenway, Boston 15, Chairman.

New York State Association of Public Health Laboratories, Albany, Nov. 7. Miss M. B. Kirkbride, New Scotland Ave., Albany 1, Secretary.

Oklahoma City Clinical Society, Oklahoma City, Biltmore Hotel, Oct. 27-30. Dr. Elmer R. Musick, 512 Medical Arts Bldg., Oklahoma City, Director of Clinics.

Omaha Mid-West Clinical Society, Omaha, Oct. 27-31. Dr. John M. Thomas, 1031 Medical Arts Bldg., Omaha 2, Secretary and Director of Clinics.

Southern Medical Association, Baltimore, Nov. 24-27, Mr. C. P. Loranz, Empire Bldg., Birmingham 3, Ala., Secretary.

Southern Psychiatric Association, Birmingham, Ala., Oct. 13-14. Dr. Newdigate M. Owensby, 384 Peachtree St. N.E., Atlanta, Ga., Secretary.

Southwestern Medical Association, Phoenix, Ariz., Hotel Westward Ho, Nov. 6-8. Dr. Louis W. Breck, 116 Mills St., El Paso, Texas, Secretary.

Virginia, Medical Society of, Roanoke, Oct. 13-15. Miss Agnes V. Edwards, 1200 E. Clay St., Richmond 19, Secretary.

Wisconsin, State Medical Society of, Milwaukee, Hotel Schroeder, Oct. 6-8. Mr. Charles H. Crownhart, 110 E. Main St., Madison 3, Secretary.

GOVERNMENT SERVICES

ARMY

MEETING OF MEDICAL OFFICERS IN KOREA

The second meeting of the U. S. Army medical officers on duty in Korea was held at the 34th General Hospital near Seoul, August 13, and was attended by about fifty officers in addition to those on the staff of the hospital. The commandant, Lieut. Col. John J. Marren, introduced Col. Charles F. Ward, recently assigned as surgeon of the 24th Corps, who outlined the work of the corps surgeon's office. The chairman of the meeting, Major Robert M. Hardaway, chief of surgical service, presented a paper on "Congenital Atresia of the Ileum," which was discussed by Capt. James S. Clarke, chief of surgical service in the 71st Station Hospital. Capt. Henry T. Allgood, chief of orthopedic service, 34th General Hospital, presented a paper on "Gas Gangrene," which was discussed by Capt. J. D. Beaver, chief surgical service, 382d Station Hospital. This paper was based on the case of a soldier who had an open fracture of the astragalus; and although the wound was completely debrided within two hours after injury, gas gangrene developed and necessitated a midthigh amputation to preserve life. In the forenoon ward rounds and departmental conferences were held, and many interesting cases were discussed. In the evening a buffet dinner was enjoyed at the officers' club at the hospital. The next meeting of the medical officers in Korea was scheduled for September 24 at the 71st Station Hospital, APO 235.

RESERVE CORPS TRAINING AT CINCINNATI

The president of the University of Cincinnati, Raymond Walters, announces the establishment of a new Medical Reserve Officers' Training Corps program for the College of Medicine. The training will be voluntary, will consist of one hour of lectures each week and will involve no uniforms and no drill. Students taking the advanced course (third and fourth years in the four year program) will receive $21 a month pay from the Army, and commissions as first lieutenants in the Medical Reserve Corps will be awarded on graduation from medical school and completion of the ROTC training. The unit is one of forty-three in medical schools throughout the country and part of a broadly expanded preparedness program. In charge of the unit at the University of Cincinnati will be Major C. C. Alden Jr., formerly of Buffalo, who served as battalion surgeon with the 509th Paratroop Battalion in Europe in World War II. Major Alden was called to active duty at the completion of his internship at the Buffalo General Hospital in 1940. He parachuted into North Africa and Italy, served at Anzio and in the Battle of the Bulge, was twice taken prisoner and twice escaped, was awarded the Distinguished Service Cross, Legion of Merit, Silver Star, Purple Heart and nine battle stars. He joined the Regular Army in 1946.

THE YALE ROTC UNIT

A Reserve Officers' Training Corps medical unit, designed to take advantage of special facilities in preventive medicine and public health at Yale University School of Medicine, was activated at the opening of the fall term. The Yale unit, one of forty-three similar units being set up at medical schools throughout the nation, expects eventually to enroll, voluntarily, at least half of the physically-fit male students who are United States citizens. Students enrolling in the new program will be required to take a four year elective course in military medicine, unless credit is given them for military service or previous ROTC training. Since the majority of male students now registered in medical schools are veterans, most of these signing up for ROTC medical training will not begin work in military medicine until their third year of medical school. Third and fourth year medical students enrolling in the advanced course at Yale will be given special instruction in military preventive medicine, field medicine and surgery, the medical aspects of atomic warfare and other technical subjects of a military nature.

Students registering for the advanced course will be required to sign a contract agreeing to complete two years of work in military medicine and to attend an eight week period of summer training between their third and fourth year of medical school. Advanced course students in the program will be paid at the rate of $23.70 a month while in medical school and $75 a month during the summer training period. Six weeks of this summer training will be given at the Army Medical Center, Washington, D. C., and two weeks at Fort Belvoir, Va. On the successful completion of the advanced course, medical school graduates will be offered commissions as first lieutenant, Army Medical Corps, Organized Reserve.

Major Douglas Lindsey, M.C., U. S. A., who has been named assistant professor of military science and tactics at Yale, will work in close connection with the Departments of Preventive Medicine and Public Health. Major Lindsey graduated from the Yale School of Medicine, served overseas as infantry battalion surgeon with the Second Battalion 175th Infantry, 29th Division, and holds the Silver Star, Bronze Star and Purple Heart medals. In addition, Major Lindsey is assistant resident in surgery at the New Haven Hospital.

AVIATION MEDICAL EXAMINERS GRADUATE

One hundred medical officers graduated from the course for aviation medical examiners at the School of Aviation Medicine, Randolph Field, Texas, September 12. The course covering a period of nine weeks is designed to instruct medical officers in the special duties of aviation medical examiners, to indoctrinate them in flying training, and familiarize them in the coordination of such duties with other activities which they may be called on to perform. Among those graduating September 12 were Major Humberto H. Cabrera of the Mexican Army and Major Marcial Baeza of the Army of Chile. The graduation address was made by Major Gen. Howard M. Turner, commanding general of the Tenth Air Force.

ARMY AWARDS AND COMMENDATIONS

Lieutenant Colonel William G. Dunnington

The Legion of Merit has been awarded to Lieut. Col. William G. Dunnington, M. C., U. S. Army, of Cherokee, Okla. The citation read in part as follows: For exceptionally meritorious conduct in the performance of outstanding services, as commanding officer, 184th Medical Battalion, Separate, attached to XIII Corps, from Nov. 8, 1944 to May 8, 1945. He displayed outstanding professional and executive ability, initiative and good judgment in supervising the work of his battalion, which was engaged in numerous medical tasks not ordinarily undertaken by such an organization. His excellent performance and devotion to duty reflect great credit on himself and on the armed forces of the United States. Dr. Dunnington graduated from the University of Oklahoma School of Medicine in 1934 and entered the military service in September 1940.

NAVY

JOINT ARMY-NAVY MEDICAL SUPPLY CATALOGUE

The new joint Army-Navy medical supply catalogue which was begun in 1945 has finally been issued. Every medical and hospital facility of the Army and Navy will receive a copy when distribution is complete. This large volume has been hailed by the Secretary of Defense and the two Surgeon Generals as an invaluable instrument of increased efficiency and economy and an important milestone in the logistics of military medicine. The nearly 8,000 items listed range from such inexpensive expendable articles as tongue depressors to large pieces of equipment which costs thousands of dollars. The items in the book are divided into fourteen classes, among which are 5,026 JAN items which are adaptable for both Army and Navy use; the remainder of the listings are on "limited service" supply, which means that their use is being discontinued. The catalogue is so fully indexed that an article can be located by its name or number in a few moments. In recognition of the simplified thoroughness of the new catalogue the Veterans Administration and the U. S. Public Health Service have indicated that they will adopt a similar style. The task of composing this thick volume was launched under former Surgeons General Norman T. Kirk, U. S. Army, and Vice Admiral Ross T. McIntire (MC), U. S. N. (retired). The ultimate result may be a single federal medical supply catalogue providing special designation for items used by only one service, comparable to the Army-only and Navy-only designation in the present volume.

SAFETY AWARDS

The Secretary of the Navy Award for Safety has been awarded by former Secretary of the Navy James Forrestal to the U. S. Naval Hospital and the Naval Medical Supply Depot, Oakland, Calif., for a reduction in the accident rate of 54 per cent for the hospital and 39 per cent for the depot. Notice of this award to the U. S. Naval Hospital, Annapolis, Md., appeared in The Journal, September 13, page 103.

NAVY AWARDS AND COMMENDATIONS

Commander John L. Tullis

The Navy Commendation Ribbon has been awarded to Comdr. John L. Tullis (MC), U.S.N. The citation read as follows: For meritorious service in connection with the Naval Medical Research Section of Operation Crossroads. He competently and efficiently carried out the pathologic work of the section to obtain information of the utmost value in assaying the effects of atomic bomb radiations on animals. His industry and skill have set a splendid example for those working under him. As division officer he performed his duties in a highly capable manner, and as pathologist he demonstrated an unusual degree of ability, which contributed to the successful conduct of the Atomic Bomb Tests. Dr. Tullis graduated from Columbia University College of Physicians and Surgeons, New York, in 1938 and entered the Regular Navy Medical Corps in 1943.

VETERANS ADMINISTRATION

ESTIMATE OF NUMBER OF VETERANS ALIVE IN THE YEAR 2000

The Veterans Administration has made a projection to estimate what its administrative and operating requirements will be in the future. The projection begins with the potential World War II population of 16,051,000 as of July 25, 1947. This number includes those released by the armed forces who are still living and those yet to be released as veterans of World War II. The average age of this group on that date was 28.6 years. The Veterans Administration computes that 3,400,000 World War II veterans will be alive in the year 2000. The projection ends with the year 2030, when it is expected that less than a thousand World War II veterans will be alive, at an average age of 104 years. The peak of medical care for World War II veterans is expected to be in 1975 when it is expected that 12,700,000 will be living at the average age of 57 years.

The number of World War I veterans still living as of June 30, 1947 was 3,727,000, and their average age then was 57 years.

HOSPITAL NEWS

Eleven hundred additional temporary beds will be provided in Downey Hospital near North Chicago, Ill., through remodeling of buildings and facilities built during the expansion of the Great Lakes Naval Training Station in 1943 on ground adjoining the Veterans Administration facility. Six hundred of these beds will be for tuberculosis cases and 300 for neuropsychiatric cases. It is estimated that four months will be required to remodel the buildings and obtain the necessary additions to the hospital staff.

CONTRACT FOR HOSPITAL IN BROOKLYN

The War Department announces that the Corps of Engineers has awarded the contract for the construction of the main building of the 1,000 bed hospital at Fort Hamilton, Brooklyn, for $14,700,000, which is $2,000,000 less than the original low bid. The saving was brought about by deleting the auditorium and making various other changes in the plans.

PRIVATE HOSPITAL CARE

According to the *New York World Telegram,* August 26, private hospital care for New York veterans with service connected disabilities will be discontinued except in cases of emergencies. Many veterans now being treated in private hospitals for tuberculosis and neuropsychiatric disorders will be transferred to federal hospitals, depending on the availability of beds and in a manner consistent with sound medical judgment. This move is being made in the interest of economy.

PERSONAL

Dr. Henry I. Berman, Pikeville, Ky., has accepted a position in the urology department of the Veterans Administration Hospital at Dayton, Ohio.

Dr. Francis J. Phillips has been assigned as chief, thoracic surgery, at the Veterans Hospital, Temple, Texas, instead of surgical chief. Dr. Bromley S. Freeman is chief of the surgical service at this hospital.

Dr. Paul C. Clark has joined the neuropsychiatric division of the staff of the veteran's hospital at St. Petersburg, Fla. Dr. Clark was for several years on the staff of the Columbus (Ohio) State Hospital and clinical director and assistant superintendent at the Huntington State Hospital in West Virginia.

Dr. Mark W. Garry, a graduate of Marquette University School of Medicine, Milwaukee, has accepted the position of chief of medical services for the Veterans Administration Hospital at Wood, Wis.

Dr. Louis G. Welt, clinical instructor of medicine at Yale University School of Medicine, New Haven, and practitioner of medicine in Connecticut since 1939, has been appointed to a medical research post with the Veterans Administration in Washington, D. C.

Dr. George A. Leonard, formerly of Waterbury, Conn., has been appointed chief medical officer of the VA regional office in New Orleans.

Ruth Addams, New York, has been appointed to the Veterans Administration central office nursing staff as a specialist in community nursing to work with the Red Cross, and other local groups, in seeing that adequate nursing care is available for disabled veterans in their communities and homes after their discharge from Veterans Administration hospitals.

Dr. Oscar Auerbach, chief, laboratory services, Halloran Veterans Administration Hospital, New York, recently returned from a month's tour of duty with the Mexican Society for the Study of Tuberculosis. Dr. Auerbach conducted a four weeks' course during August in pathology in chest diseases at the invitation of the president of the society.

PUBLIC HEALTH SERVICE

RESEARCH FELLOWSHIPS AVAILABLE

The Surgeon General, U. S. Public Health Service, has been given authority to establish and maintain research fellowships which are intended to promote training and development of investigators in the field of medicine and related sciences. The following types of research fellowships are to be awarded:

1. A predoctorate fellowship is available to qualified applicants who have a Bachelor's Degree. The stipend for successful applicants without dependents is $1,200 and for those with dependents $1,600 per annum. The tuition fee is paid by the Public Health Service. These fellowships are also granted to medical students who have finished one or two years of their medical course and contemplate a career of research and who wish to spend two or three additional years in a basic science before completing their studies toward their M.D. degree.

2. A predoctorate fellowship is available to qualified applicants holding a Master's Degree or its equivalent and carries a stipend, in addition to tuition, of $1,600 or $2,000 for persons without or with dependents, respectively.

3. A postdoctorate fellowship is available to qualified persons holding a Doctor's Degree in medicine or related fields. It carries a stipend of $3,600 for those with and $3,000 for those without dependents; it does not provide tuition fees. An increase of $300 each year is granted to those who are reappointed.

4. Special research fellowships are awarded to applicants who are qualified for a postdoctorate fellowship and who in addition have demonstrated outstanding ability or have special training for a specific problem. The stipened is determined in each individual case.

These fellowships permit vacations in accordance with the rules of the institution where the work is being done but not to exceed one month during the term of the fellowship. Progress reports are required at the end of eight months for fellows who contemplate reappointment and at the end of the fellowship from all others. Fellows are permitted to carry on not more than one hour of teaching or lecture or three hours of laboratory instruction per week during one semester only. Although fellowships are awarded about every three months, the date of beginning work can be set at any time to suit the convenience of the applicant or institution.

Forms for application for a research fellowship may be obtained from the Division of Research Grants and Fellowships, National Institute of Health, Bethesda 14, Md. The application must be supported by transcripts of scholastic records and by letters of recommendations from persons named by the applicant in the completed form. A list of all research projects which the U. S. Public Health Service supported from Jan. 1, 1946 to Aug. 31, 1947 shows a total of $10,214,174 made available to investigators. The largest number of projects (114) were in the field of cancer, the second largest (52) in physiology and the third (49) in biochemistry and nutrition. The Public Health Service also released the names of all the investigators, their projects, the institutions and the amount of money granted in each case.

NEW MEMBERS OF MENTAL HEALTH COUNCIL

The U. S. Public Health Service announces the appointment of two new members of the National Advisory Mental Health Council: Dr. Alan Gregg, Rockefeller Foundation, New York, and Dr. Karl M. Bowman, San Francisco, to succeed Dr. Frank F. Tallman of Columbus, Ohio, and Dr. George S. Stevenson, Redbank, N. J., who on the expiration of their terms on the Council were appointed consultants in mental health to the Public Health Service.

The following have been appointed to the headquarters staff of the mental hygiene division of the Public Health Service: Dr. Raymond V. Bowers, formerly with Selective Service as chief of research; John C. Eberhard, formerly on the staff of the psychology division of Northwestern University, Chicago; Miss Esther A. Garrison, a nurse officer in the Public Health Service, and Miss Pearl Shalit, formerly with the Family Nursing Service, St. Paul.

MISCELLANEOUS

THE ISOTOPE DISTRIBUTION PROGRAM

The U. S. Atomic Energy Commission, Isotope Branch, reports in *Science* that during the first year of distribution, ending July 31, 1947, pile-produced radioisotopes were shipped to more than one hundred and sixty institutions and organizations located in thirty-one states and in the territory of Hawaii. At the head of the list of recipients are medical institutions and hospitals, followed by educational institutions for use in research; industrial and private organizations for use in research; then public and private nonprofit institutions other than educational. About sixty different radioisotopes were shipped—a major portion of available kinds.

Hundreds of different uses are being made of distributed radioisotopes, but outweighing the others in number and importance at present are the tracer investigations (including medical diagnosis) and medical therapy. Investigations have been carried on in the fields of agriculture, plant physiology, industrial research, chemistry, bacteriology and metallurgy. In chemistry the principal emphasis has been on the use of labeled molecules in the study of reaction and exchange mechanisms. Physicists have used radioisotopes in their effort to arrive at more accurate measurements of disintegration patterns.

Great improvement was made during the year in the routine production of many items at the Clinton Laboratories, Oak Ridge, Tenn. Production of the majority of items is now adequate to meet the legitimate demands of all users who can handle the material effectively and safely.

Research workers may now secure service irradiations of their own materials (suitable for exposure in the Clinton pile). The Argonne National Laboratory, Chicago, has also recently undertaken to perform certain service irradiations for qualified investigators by means of the Argonne heavy-water pile. Improved methods of producing radioactive carbon (C^{14}) have permitted a reduction in the cost of this extremely important isotope from $367 to $50 per millicurie.

Information on health protection, the commission reports, is one of the most frequent requests received in connection with this program, and several circulars on health protection are available. Details concerning the availability and procurement of isotopes and related information may be obtained by writing the Atomic Energy Commission, P. O. box E, Oak Ridge, Tenn.

Medical News

(Physicians will confer a favor by sending for this department items of news of general interest: such as relate to society activities, new hospitals, education and public health. Programs should be received at least two weeks before the date of meeting.)

CALIFORNIA

Graduate Assembly at San Diego.—The staff of the San Diego County General Hospital has arranged a graduate assembly for October 6-8, to which all physicians are invited. No charge will be made for attendance. Physicians who will lead the discussion include:

Thomas J. Dry, Rochester, Minn.
Rubin Flocks, professor of genitourinary surgery, State University of Iowa College of Medicine, Iowa City.
Frank R. Lock, professor of obstetrics and gynecology, Bowman-Gray Medical School, Winston-Salem, N. C.
Edward B. Shaw, associate clinical professor of pediatrics, University of California Medical School, Berkeley-San Francisco.
John B. De C. M Saunders, professor of anatomy, University of California Medical School.
Le Roy C. Abbott, professor of orthopedic surgery, University of California Medical School.
John R. Paxton, assistant clinical professor of surgery, University of Southern California School of Medicine, Los Angeles.

Morning sessions will be held in the San Diego County General Hospital and afternoon sessions at the U. S. Naval Hospital.

Eye Laboratory Established in Los Angeles.—The Estelle Doheny Eye Foundation announces the establishment of an Eye Laboratory at St. Vincent's Hospital, Los Angeles. The immediate functions of the laboratory are (1) to serve for the diagnosis and registration of pathologic specimens, with preparation of gross specimens and microscopic slides for ophthalmologists submitting specimens, and for building up a museum of Eye Pathology; (2) to serve as a bacteriologic laboratory wherein diagnostic scrapings, smears and cultures can be studied, animal inoculations made, and the sensitivity of organisms to various drugs and antibiotics determined; (3) to provide facilities for fundus, gross and slit lamp photography and to maintain a library of photographs and motion pictures for teaching ophthalmology; (4) to provide an "Eye Bank" for Southern California, with registry of potential donors and recipients, and (5) to distribute and loan certain drugs and equipment for radiation therapy of the eye for use outside the laboratory. Dr. A. Ray Irvine, professor of ophthalmology, University of Southern California School of Medicine, Los Angeles, will act as chairman of the original board. On the advisory board will be Drs. Alan C. Woods, professor and director of the department of ophthalmology at Johns Hopkins Medical School, Baltimore; Cecil S. O'Brien, head of the department of ophthalmology at Iowa Medical School, and Phillips Thygeson, former professor of ophthalmology at Columbia University College of Physicians and Surgeons, New York, and now associate professor at the University of California Medical School, Berkeley-San Francisco. It is contemplated that the advisory board will also include business and professional leaders as well as representatives from the eye departments of Los Angeles hospitals, medical schools and the eye section of the Los Angeles County Medical Society. Dr. Peter Soudakoff, Los Angeles, formerly associate professor of ophthalmology at the Peking Union Medical College, Peiping, China, will serve as full time pathologist at the laboratory. It is anticipated that research associates, granted fellowships in basic ophthalmic research by the foundation, will be added to the laboratory staff from time to time. In creating this charitable foundation, dedicated to the conservation and restoration of sight, Mrs. Edward Laurence Doheny has been careful to insure a flexibility of organization to take care of immediate practical needs and to provide for the development of research in ophthalmology.

DISTRICT OF COLUMBIA

Orientation Program.—George Washington University School of Medicine inaugurated a two week orientation program for members of the 1947 freshman class beginning September 15. The program was designed to acquaint students with medical terminology and to show them the relationship of medicine with physics, biology, sociology and chemistry. Lectures were also given on the evaluation of scientific evidence and basic sciences in medicine. Discussions followed each address.

Personals.—George Washington University has appointed Dr. Luther Sheldon Jr., rear admiral, U. S. N., retired, as associate university physician, thereby opening campus medical facilities for students daily from 9 a. m. to 5 p. m. Dr. Elizabeth S. Kahler, who has been associate university physician for several years, will also be on duty.——Dr. William W. Stanbro has been appointed chief roentgenologist at George Washington University Hospital and assistant professor of radiology at the University School of Medicine. Dr. Stanbro has just completed residence on a fellowship at the Mallinckrodt Institute of Radiology, Washington University School of Medicine, St. Louis, Mo., where he also received his degree in medicine.

ILLINOIS

Personal.—Dr. James H. Davis, Carlinville, has received a fifty year certificate from the Macoupin County Medical Society. Dr. Davis, a graduate of Northwestern University Medical School, Chicago, 1897, has spent most of his fifty years in practice in Carlinville.

Joint Meeting of Tuberculosis Societies.—A joint meeting of the Illinois chapters of the American Trudeau Society and the American College of Chest Physicians was held at the Abraham Lincoln Hotel, Springfield, October 2 at 2 p.m. Dr. Charles K. Petter, Waukegan, spoke on "The Need for Periodic X-Ray Examination of Adult Chests"; Dr. Darrell H. Trumpe, Springfield, "Role of Bronchoscopy in Diseases of the Chest"; Dr. George H. Vernon, Springfield, "Our Experience with Streptomycin and Summary of Present Status," and Dr. Jesse A. Stocker, Springfield, "Limitations of Collapse Procedures." At the regular meeting of the Sangamon County Medical Society that evening Dr. J. Arthur Myers, University of Minnesota Medical School, Minneapolis, spoke on "Tuberculosis in General Practice and the Specialties."

Lectures Arranged by the State Society.—The Scientific Service Committee of the Illinois State Medical Society has scheduled the following lectures:

October 9—Six County Medical Society in Anna State Hospital, Anna, Dr. Louis R. Limarzi, Chicago, "Common Blood Disorders in General Practice," and Dr. Frederic A. Gibbs, Chicago, "Epilepsy." Will-Grundy County Medical Society, Joliet, Dr. Leon O. Jacobson, Chicago, "Radioactive Therapy."

October 16—Logan County Medical Society, Lincoln, Dr. E. Harold Ennis, Springfield, "Rh Factor."

November 20—Logan County Medical Society, Dr. F. Garm Norbury, Jacksonville, "Psychosomatic Medicine."

The following Chicago physicians are lecturing to Parent-Teacher Associations under the auspices of the Educational Committee of the Illinois State Medical Society:

October 9—Dr. Paul Starcevich, "Various Aspects of Nutrition," at the Matteson Public School, Matteson.

October 10—Dr. Morris Braude, "Mental Hygiene," at the Gross School, Brookfield.

Chicago

Society News.—The Chicago Society of Allergy at its annual meeting elected Drs. Theodore B. Bernstein president, Edward G. Tatge president-elect and Morris A. Kaplan secretary-treasurer.——At its latest meeting the Chicago Orthopaedic Society elected Drs. Harold A. Sofield president, John R. Norcross president-elect and Manley A. Page secretary-treasurer.

Assistant Medical Director of University Hospitals.—Dr. Myron C. Benford, Chicago, head of the outpatient department of the University of Illinois hospitals since 1942, has been promoted to assistant medical director, to assist Dr. John B. Youmans, dean of the college of medicine and medical director of the hospitals. Dr. Benford is a 1935 graduate of the university's College of Medicine and was appointed to the faculty in 1937. He later served as assistant superintendent of the hospitals.

Dr. Bailey Promoted to Distinguished Professor.—Dr. Percival Bailey, who has been on the faculty of the University of Illinois since 1929, has been promoted to the rank of distinguished professor of neurology and neurologic surgery. Dr. Bailey received his M.D. degree from Northwestern University, 1918. He has conducted research in neurology, neurophysiology, pathology and surgery. During the last five years he has conducted research on the organization of superficial layers of the brain. He has also been a member of the faculty at Harvard Medical School, Boston, Northwestern Medical School, and the University of Chicago School of Medicine.

Share Fellowship in Cancer Research.—A grant of $2,000 for a fellowship in cancer research in the field of pathology has been made to the Northwestern University Medical School by the Illinois Federation of Women's Clubs. The fellowship will be shared by Drs. Joseph T. Chung and Thomas J. Madden, research men working under the direction of Dr. William B. Wartman, Morrison professor of pathology and chairman of the department. Dr. Chung's research is centered in the application of a cell-staining method for the early diagnosis of cancer. Dr. Madden, working in the field of biochemistry, is studying enzymes and their relation to malignant neoplasms.

INDIANA

College Honors Dr. Stanley.—Physicians and other scientists gathered at Earlham College, Richmond, September 19, as a part of the school centennial celebration, to honor Wendel M. Stanley, Ph.D., Princeton, N. J., of the Rockefeller Institute of Medical Research. Dr. Stanley gave an address in Carpenter Hall on studies on purified influenza virus. He is a graduate of Earlham College and a winner of the Nobel prize for "achievement in preparing enzymes and virus proteins in pure form."

State Society to Award Scholarships to Nurses.—The council of the Indiana State Medical Association in July took action to give scholarships of $200 each to six girls for training in any one of the twenty-eight accredited nursing schools of the state. It also decided to award medals in the name of the association to the three students with the highest grades in each graduating class of the Indiana University School of Medicine, Bloomington-Indianapolis. Six $500 medical school scholarships were awarded last January.

LOUISIANA

Society News.—At the annual meeting of the New Orleans Gynecological and Obstetrical Society July 1 the following officers were elected: Dr. Earl C. Smith, president; Dr. Woodward D. Beacham, president-elect; Dr. John S. Herring, secretary, and Dr. Harry Meyer, treasurer.

Academy of General Practice.—At the organization meeting of the American Academy of General Practice of New Orleans, held August 20, Drs. Joseph C. Menendez was elected president, Esmond A. Fatter, vice president, and Robert E. Gillaspie, secretary-treasurer. Dr. Jason P. Sanders, Shreveport, president of the American Academy of General Practice of Louisiana and a representative on the board of directors of the national organization, addressed the group.

Louisiana Faculty Appointments.—The Louisiana State University School of Medicine, New Orleans, has announced the following appointments: Drs. Harry E. Dascomb, instructor in medicine; Robert M. Waters, instructor in surgery; John J. Blasko, clinical instructor in neuropsychiatry; Louis Raider, New York, clinical instructor in radiology, Simon V. Ward Jr., clinical instructor in obstetrics and gynecology; Harold S. Gamble, assistant in anatomy; John D. Krafchuk, assistant in microbiology; James T. McQuitty, clinical assistant in surgery, and Robert D. Bone, clinical assistant in medicine.

MAINE

Elected to National Board.—Dr. Adam P. Leighton, Portland, was unanimously elected to the National Board of Medical Examiners recently at its meeting. He succeeds the late Dr. James D. Osborn, Frederick, Okla., who died February 7, and whose term would have expired in 1949.

MARYLAND

Semiannual Meeting of State Association.—The Medical and Chirurgical Faculty of Maryland will hold its semiannual meeting at the auditorium, County Office Building, Easton, October 9 at 10:30 a.m. At the general meeting beginning at 2:30 p.m. Dr. George W. Thorn, Hersey professor of the theory and practice of physics, Harvard University Medical School, Boston, will speak on "Treatment of Renal Insufficiency."

NEBRASKA

University Appointments.—Dr. Pliney Allen has been appointed assistant professor of pathology at the University of Nebraska College of Medicine, Omaha, and has accepted the position of pathologist at the Immanuel Deaconess Institute in Omaha. A graduate of Harvard Medical School, Boston, he has taken training at the Mayo Foundation and has been associated with Charity Hospital of Louisiana and the Louisiana State University School of Medicine, New Orleans, and the Joseph H. Pratt Diagnostic Hospital in Boston. Robert M. Allen, Ph.D., has been appointed assistant professor of bacteriology.——Dr. James P. Tollman has been appointed chairman of the department of clinical pathology and bacteriology at the University of Nebraska College of Medicine, Omaha. He has been associated with the institution almost continuously since his graduation in medicine there in 1929. Dr. John R. Schenken, associate professor of pathology, has been appointed professor of pathology and acting chairman of the department of gross and micros pathology. He is a graduate of the State University of Iowa College of Medicine, Iowa City, 1928, and was professor and head of the department of pathology and bacteriology at Louisiana State University School of Medicine, New Orleans, 1939-1945, when he came to the University of Nebraska College of Medicine.

NEW YORK

Mental Deficiency Section Meeting.—The northeastern section of the American Association on Mental Deficiency is holding a meeting at the Wassaic State School, Wassaic, N. Y., October 18. During the morning hours the school will be open for inspection. After luncheon the following papers will be given and discussed: Drs. Ernest S. Steblen and Joseph E. Rosenfeld, "An Analysis of the Relationship of the Moron Group to State School Training"; Patrona F. Morgan, "Social Service in the Realm of Mental Deficiency," and Percy H. Larrabee, O.T.R., "Occupational Therapy with Mental Defectives."

Conference on Radioisotopes.—Brookhaven National Laboratory, Upton, will hold a conference on the use of radioisotopes in medical and biologic research, October 16-18. Topics include: "Legal Aspects in Use of Radioactive Materials," "Protective Measures for Personnel," "Protective Measures for Public Health," "Procedures Used in Examination of Individuals Exposed to Radioactive Materials," "Procurement of Isotopes," "Shipping of Isotopes," "Handling of Radioactive Materials" and "Disposal of Radioactive Waste Materials." Those interested in attending should communicate with Miss Ellen Matteson, Secretary, Conference Committee, Brookhaven National Laboratory, Upton.

Lectures for County Societies.—The Medical Society of the State of New York in cooperation with the New York State Department of Health has arranged a program for the Schenectady County Medical Society for October 7 at 8:30 p.m. in the library at Ellis Hospital, Schenectady. Dr. John R. Cobb, assistant orthopedic surgeon, Hospital for Special Surgery, New York, and Thomas I. Hoen, professor of neurosurgery, New York Medical College Flower and Fifth Avenue Hospitals, New York, will take part in a symposium on low back pain. The Seneca County Medical Society is to hear Dr. Richard S. Farr, professor of orthopedic surgery, Syracuse University College of Medicine, Syracuse, speak on "The Treatment of Fractures by the General Practitioner" on October 16 at 2 p.m. at the Willard State Hospital, Willard.

New York City

Long Island College to Confer Doctor of Medical Science.—The Long Island College of Medicine, Brooklyn, has been authorized to confer the degree of Doctor of Medical Science by the state board of regents, following the expansion of teaching activities to include graduate training in psychiatry. Graduate courses in other fields will be organized as the necessary space and instructors become available. The college has heretofore sponsored only a part-time program of graduate training. The three year graduate teaching program is under the direction of Dr. Howard W. Potter, professor of psychiatry.

Dedicate Building for School of Nutrition.—The new home of the school of nutrition at Cornell University will be dedicated October 10. Speakers representing the government, health and science groups, the farmer and the university, will discuss "Nutrition—A Key to Human Welfare." Among the speakers will be Governor Thomas E. Dewey; Congressman Clifford R. Hope of Kansas, chairman, congressional agriculture committee; Dr. William H. Sebrell Jr., U. S. Public Health Service, Bethesda, Md.; Frank M. Smith, Springfield Center, N. Y., chairman, New York State Conference Board of Farm Organizations; Dr. Leonard A. Maynard, director of the School of Nutrition, and Neal D. Becker, New York, chairman of the Cornell University Board of Trustees. The new building will provide much larger facilities for teaching and research for the school of nutrition, which was established in 1941. The building is named in honor of Professor Elmer S. Savage, a member of the faculty for thirty-five years until his death in 1943.

VIRGINIA

The Hundredth Annual Meeting of State Society.—The Medical Society of Virginia will hold its hundredth annual meeting October 13-15 at Roanoke, under the presidency of Dr. William L. Powell. Besides numerous members who will speak on the scientific program, the guest speakers include:

Richard H. Shryock, Ph.D., Philadelphia, Progress of Medicine in America in the Past One Hundred Years.
W. Halsey Barker, Baltimore, Gastro-Intestinal Symptoms Occurring in Disorders Located Outside of the Gastro-Intestinal Tract.
Frederick A. Coller, Ann Arbor, Mich., Peripheral Diseases and the Newer Concepts of Their Management.
Frank E. Smith Jr., New York, The Doctor Assumes a Moral Responsibility.

Entertainment includes a birthday party of the one hundredth meeting Monday evening and a banquet Tuesday at 7:15 p.m. followed by a dance. The Alumni Association will have a dinner meeting Monday at 6 p.m., and the breakfast of the American Academy of General Practice, Virginia Section will be Tuesday morning at 8 o'clock. Special society luncheons are scheduled for Tuesday at 1:15 p.m. The Woman's Auxiliary will meet October 14-15.

WEST VIRGINIA

The Loss of Containers for Laboratory Specimens.—A regulation adopted at a recent meeting of the public health council prohibits the use of containers provided by the West Virginia state hygienic laboratory for purposes other than sending specimens for examination and diagnosis of diseases to that laboratory. The regulation is effective October 1. The annual loss of containers has long been a serious problem, and drastic steps had to be taken lest the laboratory be compelled to discontinue furnishing this service. The loss to the laboratory last year amounted to about $12,000 because of the failure to return containers, which are mailed without charge to physicians, hospitals and public health agencies throughout the state.

Health Departments Merge.—The merger of the Kanawha County health department with the health department of the city of Charleston was completed July 1. The consolidation was effected under the provisions of a bill passed by the legislature at the regular session early in 1947. Merger of the city and county health units has long been advocated by the West Virginia State Medical Association. The new department will be under the supervision of a board of health. Appropriation for the expenses of the new unit for the fiscal year ending June 30, 1948, amounts to $64,000, the city and county each having appropriated one half that amount. Present facilities in the city hall and court house will be used until new quarters can be provided.

GENERAL

Foundation Changes Name.—The name of the National Research Foundation for Eugenic Alleviation of Sterility, Inc. has been amended in accordance with the law and has been changed to National Research Foundation for Fertility, Inc., according to the executive secretary, Dr. Alfred Koerner, New York.

Dr. Harper Given Pediatric Award.—Dr. Paul S. Harper, Fairfield, Conn., received the Mead Johnson pediatric award at the annual meeting of the Academy of Pediatrics in Pittsburgh in May. The award was presented for work on "malaria and other insect borne diseases in the South Pacific" carried on while in the military service.

American Institute of Physics.—Mr. Cleveland Norcross, Washington, D. C., at present executive secretary of the Office of Scientific Research and Development, has been appointed assistant director of the American Institute of Physics, which is a federation of the American Physical Society, the Optical Society of America, the Acoustical Society of America, the American Association of Physics Teachers and the Society of Rheology.

American Board of Obstetrics and Gynecology.—The next written examination (Part I) for all candidates will be held in various cities of the United States and Canada on Friday, Feb. 6, 1948 at 2 p.m. Candidates who successfully complete the Part I examination proceed automatically to the Part II examination held later in the year. A number of changes in regulations and requirements were put into effect at the last annual meeting of the Board in Pittsburgh, June 1-7 (The Journal, July 5, page 910). Applications are now being received for the 1948 examinations. The closing date is Nov. 1, 1947. For application blanks address Paul Titus, M.D., Secretary, 1015 Highland Building, Pittsburgh 6, Pa.

Study Atomic Bomb Survivors.—The Atomic Energy Commission together with the National Research Council will undertake a long range study of the survivors of the atomic bomb attacks on Hiroshima and Nagasaki, to be financed by the commission and directed by the council's committee on atomic casualties, organized recently as a result of a directive issued by President Truman. Dr. Thomas M. Rivers, Rockefeller Institute for Medical Research, was appointed chairman of the committee, whose members include a number of the country's leading authorities on the effects of radiation. The investigations will attempt to determine the effect of atomic radiation on the blood cells, on the physical growth of children, on the mechanisms of heredity and on the development of various pathologic conditions including the formation of massive scar tissue. The commission said that the program will be carried out in Japan under American physicians with Japanese doctors and scientists also taking part. The study of genetics and heredity may continue over a period of years.

Nurse Receives Medal for Merit.—At a press conference in the Social Security Building, Washington, D. C., September 17, the Surgeon General, U. S. Public Health Service, presented the medal for merit to Mrs. Elmira Bears, Bronxville, N. Y., executive secretary, national nursing council for war service, 1941-1947, in recognition of her contribution in the war effort of the United States. She is the third woman in the history of the nation to be so honored. She has served as nurse adviser of the United States delegation to the World Health Conference, led in the development by the National Nursing Council of a pattern for evaluation and filling nursing needs, was active in establishing the Cadet Nurse Corps in the U. S. Public Health Service and has led in developing a unified program for meeting America's postwar nursing service needs.

The Lasker Awards for 1947.—Dr. Thomas Parran, Surgeon General, U. S. Public Health Service, will receive a special Lasker award of $2,500 and a gold replica of the classical Winged Victory of Samothrace, symbolizing victory over disease and death. He is being cited for his approach to the control of venereal disease which has brought about a decreasing death rate. Individual Lasker Awards for scientific research, to include $1,000 and a gold statuette, will be presented to Dr. Oswald T. Avery, New York, Rockefeller Institute for Medical Research, for studies on the antigenic constitution of bacteria, particularly the pneumococcus; Dr. Thomas Francis Jr., University of Michigan School of Public Health, Ann Arbor, for his contribution to the knowledge of influenza; Dr. Homer W. Smith, associate professor of surgery, New York University College of Medicine, New York, for studies in cardiovascular and renal physiology, and Dr. Alice Hamilton, Hadlyme, Conn., for her administrative achievement in the prevention of occupational diseases. The two group winners, each to receive a silver replica of the statuette, are the British Ministries of Food and Health for its war-induced program of food distribution in Great Britain, resulting in the improved public health standards there, and the United States Committee on Joint Causes of Death for its method of classification of disease, injuries and causes of death on a worldwide scale, facilitating the exchange of information on health and medicine between the countries of the world. The awards will be formally presented October 9, at the annual meeting of the American Public Health Association in Atlantic City, N. J. The awards were presented to the association by the Albert and Mary Lasker Foundation last year for the first time. The winners were selected from a panel of one hundred eighteen candidates by an awards committee, of which Dr. George Baehr, president of the New York Academy of Medicine, was chairman.

American Academy of General Practice.—A group of general practitioners founded the American Academy of General Practice in Atlantic City, N. J., June 10, 1947. Its purposes as outlined in the constitution are (1) to promote and maintain high standards of the general practice of medicine and surgery; (2) to encourage and assist in providing postgraduate study for general practitioners in medicine and surgery and to encourage and assist practicing physicians and surgeons to participate in such training; (3) to encourage and assist young men and women to prepare, qualify and establish themselves in general practice; (4) to protect the right of the general practitioner to engage in medical and surgical procedures for which he is qualified by training and experience, and (5) to advance medical science and private and public health. Membership is limited to members of the American Medical Association and physicians who have been in general practice at least three years and who are interested in continuing in postgraduate work. To continue as a member it is necessary to complete one hundred fifty hours of postgraduate work during each three years period. To be eligible for general membership the applicant must be a physician engaged in general practice, must have graduated from a medical school approved by the American Medical Association, must be licensed in the state in which he practices and must be a member of his local medical association. He must have had at least one year of rotating internship at an acceptable hospital or the equivalent in postgraduate training. He must have been engaged in general practice of medicine for at least five years immediately preceding his application for membership and during that time must have been engaged in some postgraduate educational activities. Any general membership shall terminate at the end of three years, and to be eligible for reelection a general member must have spent a minimum of one month during his three year period in postgraduate training of a nature acceptable to the membership committee. The officers elected were Drs. Paul A. Davis, Akron, Ohio, president; Elmer C. Texter, Detroit, vice president; Ulrich R. Bryner, Salt Lake City, treasurer, and Stanley R. Truman, Oakland, Calif., secretary.

Prevalence of Poliomyelitis.—Reports of cases of poliomyelitis for the periods indicated have been received from the division of public health methods, U. S. Public Health Service:

VIRGIN ISLANDS

Appointments in Department of Health.—Dr. Kund Knud-Hansen has retired as commissioner of health after many years of government service. The acting commissioner is Dr. John S. Moorhead, a native of St. Croix. After seven years of service, Dr. Norman D. Thetford, St. Croix, has taken a terminal leave from the post of the assistant commissioner of health and chief municipal physician. Dr. Roy A. Anduze, a native of St. Thomas, will succeed him on a temporary basis. The Virgin Islands department of health operates general hospitals and clinics and performs the usual functions of a state health department. The two top positions, commissioner of health and chief municipal physician for St. Thomas and assistant commissioner of health and chief municipal physician for St. Croix, are both federal posts in the U. S. Department of the Interior.

PHILIPPINE ISLANDS

Annual Meeting.—At the fortieth annual convention of the Philippine Medical Association in Manila May 7, the following officers were elected: Drs. Januario Estrada, president; Guillermo Rustia, president-elect, and Antonio S. Fernando, secretary-treasurer, all of Manila.

Drive Against Tuberculosis and Malaria.—The United States Public Health Service and the Philippine Health Bureau are joining to cut the island death rate from tuberculosis and malaria. Dr. Antonio Villarama, secretary of health and public welfare, is reported to have said that of one million Filipinos whose chests were x-rayed 6.5 per cent were believed to present active tuberculosis. Thirty malaria control parties through the island are attempting to lower the death rate of 91 for each hundred thousand, nearly twice the prewar rate.

CANADA

McGill to Grant Degree in Tropical Medicine.—The wartime short course in tropical medicine at McGill University Faculty of Medicine, Montreal, has been revised and additional facilities have been provided for study leading to a D.T.M. degree. The course is being conducted by the department of health and social medicine with the assistance of members of other faculties of the university. The final third of the course is a period of specially arranged supervised training in tropical countries. This includes clinical hospital practice and health unit work. For further information address the Chairman, Department of Health and Social Medicine, 490 Pine Avenue, West, Montreal, Canada.

Montreal Medico-Chirurgical Society.—The fifteenth annual clinical convention of the Montreal Medico-Chirurgical Society will be held in Montreal October 6-11. Clinical sessions will be held at various hospitals. The program will also include demonstrations and exhibits. Other meetings of the society will be as follows: On October 24, Dr. H. Jackson Morgan, professor of medicine and head of the department, Vanderbilt University School of Medicine, Nashville, Tenn., will speak on "Peptic Ulcer," and Dr. Samuel J. Shane, Yarmouth, Nova Scotia, on "Cardiac Edema and the Serum Proteins"; on November 7, Dr. Richard J. Bing, assistant professor of surgery, Johns Hopkins Hospital, on "A Selection of Cases for Cardiac Surgery"; on December 5, Dr. Walter F. Kvale, Rochester, Minn., on "The Use of 'Dicumerol.'" On Jan. 9, 1948, Dr Robert R. Linton of Brookline, Mass., will speak on "Thrombophlebitis and Phlebothrombosis in the Medical and Surgical Patient."

CORRECTION

Location of Physicians.—In the ninth of the series of articles on "Location of Physicians," in The Journal, August 30, page 1552, the city of Berkeley, Alameda County, Calif., was erroneously listed as requesting general practitioners. The opening in this instance was for an associate or partner in general practice.

Marriages

Charles Brooker Cheney, New Haven, Conn., to Miss Frances Crandall Wheelock of Orange, N. J., July 26.

Carl Worrell Roessel, New York, to Miss Barbara Madara Barclay of Mount Kisco, N. Y., August 15.

Bernard Owen Burch, Livermore, Calif., to Miss Antoinette Katherine Erro of Fresno at Carmel, June 18.

Wiley Stewart Flanagin, Jacksonville, Fla., to Miss Lillian Greenlee Tate of Murphy, N. C., July 31.

Cornelius Francis Ryan to Miss Dorothy Baumgardt, both of Oneonta, N. Y., September 3.

Frances Arlene Swan, Livonia, N. Y., to Mr. Walter H. Lieneck of Brooklyn August 16.

Thornton Tayloe Perry III, Charles Town, W. Va., to Miss Gisele Chautemps in July.

James R. Mack, Cincinnati, to Mrs. Frances Meyer Friedman of New York in August.

Edward J. Drangınis, Detroit, to Miss Nancy Singleton of Muskegon, Mich., June 28.

Thomas H. Mason, Syracuse, N. Y., to Miss Louise English of Kenmore August 2.

Hans M. Schapire to Miss Lillian Levin, both of Chicago, September 4.

Deaths

Lunsford Dickson Fricks ⊕ Medical Director, U. S. Public Health Service, retired, Seattle; born in Walker County, Georgia, July 18, 1873; Chattanooga (Tenn.) Medical College, 1897; appointed assistant surgeon, U. S. Public Health Service, in 1898, passed assistant surgeon in 1903, surgeon in 1912, senior surgeon in 1929 and medical director in 1930; retired Feb. 1, 1938; director of district number six with headquarters in Seattle from 1927 to 1935, when he became chief quarantine officer in the Hawaiian Islands; in 1942 became health officer of Helena and Lewis and Clark counties health unit in Montana; member of the American Public Health Association, Association of Military Surgeons of the United States, National Malaria Committee (serving for many years as secretary), Southern Medical Association, Veterans of the Spanish-American War and others; director of the extra cantonment sanitation, Camp Zachary Taylor, during World War I; received the degree of doctor of public health from the University of Georgia in 1926; died in U. S. Marine Hospital, July 9, aged 73, of pneumonia.

Robert Nason Nye ⊕ Boston; born in Springfield, Mass., June 3, 1892; Harvard Medical School in Boston, 1918; assistant professor of bacteriology and immunology at the Harvard Medical School; member of the American Society of Clinical Investigation and the American Association of Pathologists and Bacteriologists; director at large of the Massachusetts Tuberculosis Association; councilor of the Massachusetts Medical Society and the Harvard Medical Alumni Association; trustee and treasurer of the Boston Medical Library; served as assistant director of the division of biologic laboratories of the Massachusetts State Department of Public Health; member of the committee on information of the National Research Council and a member of the committee on information, procurement and assignment service of the War Manpower Commission during World War II; affiliated with the Boston City Hospital; managing editor of the *New England Journal of Medicine;* died September 10, aged 55, of reticulum cell sarcoma.

Walter Prentice Bowers ⊕ Clinton, Mass.; born in Clinton, May 19, 1855; Harvard Medical School, Boston, 1879; formerly secretary of the board of registration in medicine; past president of the Massachusetts Medical Society and the Worcester District Medical Society; for many years vice president and a member of the board of trustees of the Clinton Savings Bank and vice president and member of the board of directors of the Clinton Trust Company; served as selectman, a member of the board of health and a member of the town finance committee; in 1921 became managing editor of the *Boston Medical and Surgical Journal,* continuing when it became the *New England Journal of Medicine,* of which he had been editor emeritis; fellow of the American College of Surgeons; received the honorary degree of master of arts from his alma mater in 1935; founder and for many years president of the Clinton Hospital, where he died July 22, aged 92.

Hugh Page Newbill ⊕ Staunton, Va.; born in Norfolk May 28, 1909; University of Virginia Department of Medicine, Charlottesville, 1934; interned at the Norfolk Protestant Hospital in Norfolk and served a residency at the University of Virginia Hospital in University; formerly on the faculty of the Louisiana State University School of Medicine in New Orleans, where he was on the staff of Charity Hospital; formerly assistant professor of neurology and psychiatry at the University of Virginia Department of Medicine and associated with the Davis Clinic of the University of Virginia Hospital in Charlottesville; in charge of the De Jarnette Sanatorium; found dead July 2, in a cabin at Sunnyacres in Albemarle County, aged 38.

Theobald Robert Rudolf, New Orleans; born in New Orleans May 14, 1877; Medical Department of Tulane University of Louisiana, New Orleans, 1902; member of the American Medical Association; at one time taught chemistry and metallurgy in the old New Orleans College of Dentistry; for many years professor of chemistry in the Boys' High School, which later became Warren Easton High School; at one time assistant in clinical microscopy and bacteriology at the New Orleans Polyclinic; served during World War I; specialist on the medical rating board of the U. S. Veterans Administration; affiliated with the Hotel Dieu; died June 11, aged 70, of coronary occlusion.

Francis Anton Goeltz ⊕ Salt Lake City; born in New York Dec. 13, 1876; New York University Medical College, New York, 1898; specialist certified by the American Board of Urology, Inc.; member and past president of the Western Branch of the American Urological Association; past president of the Utah State Medical Society and the Salt Lake County Medical Society; fellow of the American College of Surgeons; served during World War I; affiliated with St. Mark's, Salt Lake County General and the Dr. W. H. Groves Latter-Day Saints hospitals; died June 25, aged 70, of carcinoma and heart disease.

Roy Carleton Perkins ⊕ Bay City, Mich.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1903; formerly member of the city board of education and board of health, councilor of the Tenth District of the Michigan State Medical Society; served on the Mexican border and during World War I; at one time an officer in the medical corps of the National Guard; formerly member of the state council of health; on the staffs of the Mercy Hospital and the Bay City General Hospital, where he died June 18, aged 68, of coronary thrombosis.

Rollie Hayden Alexander, Owenton, Ky.; Kentucky School of Medicine, Louisville, 1898; died in the King's Daughters Hospital, Frankfort, July 20, aged 78.

William Gilbert Anderson, New Haven, Conn.; Western Reserve University Medical Department, Cleveland, 1883; director of the gymnasium, emeritus, at Yale University; organized New Haven Normal School of Gymnastics, now known as the Arnold College; died July 7, aged 86.

Jacob Brouner Austin, South Euclid, Ohio; Western Reserve University Medical Department, Cleveland, 1902; served overseas during World War I; died July 13, aged 71, of coronary thrombosis.

James H. Benefield, Fort Smith, Ark. (licensed in Arkansas in 1903); member of the American Medical Association; served on the staff of Sparks' Hospital; died July 8, aged 80, as the result of an automobile accident.

Frances S. Carothers Blanchard, Wheaton, Ill.; Woman's Hospital Medical College, Chicago, 1885; died July 4, aged 91.

Joseph Hoge Bogle, Collinsville, Ala.; Vanderbilt University School of Medicine, Nashville, Tenn., 1900; died in the Holy Name of Jesus Hospital, Gadsden, July 5, aged 67, following an operation for stone in the bladder.

Frank E. Bowman ⊕ Detroit; Detroit College of Medicine, 1907; served on the staff of the Harper Hospital; died in the Highland Park General Hospital August 9, aged 73, of auricular fibrillation and old coronary thrombosis.

Samuel Joseph Brown ⊕ Panora, Iowa; Rush Medical College, Chicago, 1898; secretary treasurer and past president of the Dallas-Guthrie Counties Medical Society; served as mayor, councilman, school director and president of the school board; died July 5, aged 75, of angina pectoris.

William J. Brown, Dover, Ark. (licensed in Arkansas in 1903); died in St. Mary's Hospital, Russellville, June 20, aged 69.

Joseph Lyman Bryan ⊕ Xenia, Ill.; St. Louis University School of Medicine, 1906; district health superintendent, Illinois Department of Public Health; died in St. Paul, Minn., July 12, aged 66, of a skull fracture received in an automobile accident.

Delane Stow Calhoun, Ruston, La.; Washington University School of Medicine, St. Louis, 1904; died July 8, aged 68.

Robert William Carrall, Blue Island, Ill.; McGill University Faculty of Medicine, Montreal, Que., Canada, 1893; died June 28, aged 77.

William Morrill Colby, Randolph, Mass.; Boston University School of Medicine, 1898; died in Plymouth June 26, aged 79, of carcinoma of the prostate.

Charles Rodgers Conklin, New York; Albany Medical College, 1899; New York Homeopathic Medical College and Hospital, 1901; for many years medical director of the medical department of the Children's Aid Society; served on the staffs of the Vanderbilt Clinic, Laura Franklin Hospital, Metropolitan Hospital and the Flower and Fifth Avenue Hospitals, where he died July 7, aged 73, of intestinal obstruction.

Lee W. Cotton, Enid, Okla.; Missouri Medical College, St. Louis, 1887; member of the American Medical Association; served as county health officer; medical examiner for the draft board during World War I; died June 8, aged 86.

Jesse Hill Crouch ⊕ Richmond, Va.; Medical College of Virginia, Richmond, 1911; director of public health for Henrico County; formerly epidemiologist of the Montana State Board of Health and of the Fort Worth, Texas, health department; at one time health officer of Williamsburg; died in the Stuart Circle Hospital June 13, aged 60, of coronary occlusion.

John Emerson Derbyshire, Van Buren, Ind.; Rush Medical College, Chicago, 1903; member of the American Medical Association; on the staff of the Marion (Ind.) General Hospital; died June 21, aged 73, of arteriosclerosis.

James R. Des Portes, Fort Mill, S. C.; Medical College of South Carolina, Charleston, 1900; member of the American Medical Association; past president of the South Carolina Medical Association and the York County Medical Society; died June 2, aged 68.

Charles Ezekiel Dumke, Denver; Denver and Gross College of Medicine, Denver, 1906; member of the American Medical Association; died in St. Luke's Hospital June 21, aged 66, of chronic myocarditis and arteriosclerosis.

Charles Frederick Duncan, Jacksonville, Fla.; College of Physicians and Surgeons, Boston, 1910; chief of the surgical staff of the Brewster Hospital, where he died recently, aged 67, of heart disease.

William Chauncey Fox, Chicago; the Hahnemann Medical College and Hospital, Chicago, 1914; died in Fremont, Mich., June 6, aged 63.

Frederick Standish Greene, Northampton, Mass.; Yale University Medical School, New Haven, Conn., 1926; died in the Veterans' Hospital June 11, aged 49, of postencephalitic Parkinsonism.

Louis Richard Haas ⊕ Pittsburg, Kan.; Cornell University Medical College, New York, 1929; specialist certified by the American Board of Ophthalmology and the American Board of Otolaryngology; fellow of the American College of Surgeons; diplomate of the National Board of Medical Examiners; affiliated with the Mount Carmel Hospital; died June 30, aged 44, of coronary diease.

Arthur Otto Hahl ⊕ Clarence, N. Y.; University of Buffalo School of Medicine, 1908; served as medical examiner for local schools and as health officer of Clarence; died in Pasadena, Calif., June 17, aged 66, of coronary thrombosis.

Marcus Lafayette Hickson, Fort Valley, Ga.; Emory University School of Medicine, Atlanta, 1915; served during World War I; died June 18, aged 54, of heart disease.

Gregory L. Higgins, Carbondale, Pa.; College of Physicians and Surgeons, Baltimore, 1910; served on the staff of St. Joseph's Hospital; died June 25, aged 63, of fat embolism and a fractured femur received in a fall.

Benjamin Franklin Iden Jr., ⊕ Washington, D. C.; University of Virginia Department of Medicine, Charlottesville, 1909; served during World War I; on the staffs of the Doctors and Homeopathic hospitals; died July 6, aged 63.

John Martin Jackson, Aurora, Ind.; Medical College of Indiana, Indianapolis, 1905; member of the American Medical Association; served during World War I; died June 30, aged 66, of cerebral thrombosis.

Merit S. Jewell, Little York, Ill.; Louisville Medical College, 1898; member of the American Medical Association; president of the board of health; died June 28, aged 73, of cerebral hemorrhage.

Joseph Wencel Jinderlee ⊕ Cresco, Iowa; Keokuk Medical College, College of Physicians and Surgeons, 1903; died June 13, aged 73, of diabetes mellitus.

John W. Keithley, Beloit, Wis.; Kentucky School of Medicine, Louisville, 1893; member of the American Medical Association; died June 28, aged 82.

Edward Kingsley, Brookline, Mass.; Laval University Faculty of Medicine, Quebec, Canada, 1918; died May 13, aged 57, of carcinoma of the right lung.

Theodore Kuttner ⊕ New York; University and Bellevue Hospital Medical College, New York, 1906; member of the American Chemical Society; for many years associate in chemistry at the Mount Sinai Hospital; inventor of the Kuttner-Leitz microcolorimeter; died July 7, aged 70, of coronary occlusion.

Napoleon La Bonte, Clayton, Ind.; Indiana University School of Medicine, Indianapolis, 1913; member of the American Medical Association; died June 26, aged 64, of coronary occlusion and chronic duodenal ulcer.

Johan Herman Lee, Madison, Wis.; Kongelige Frederiks Universitet Medisinske Fakultet, Oslo, Norway, 1899; died in Wilmington, Calif., June 10, aged 76, of carcinoma of the colon.

William Hall Lewis ⊕ Donora, Pa.; Jefferson Medical College of Philadelphia, 1893; also a graduate in pharmacy; affiliated with Charleroi-Monesson Hospital in Charleroi; died July 3, aged 78, of arteriosclerosis and cerebral hemorrhage.

Maurice F. Linquist, New Haven, Conn.; New York Homeopathic Medical College and Hospital, New York, 1891; served on the staffs of the Hospital of St. Raphael and the Grace Hospital, where he died June 26, aged 78.

James Terry McConnaughey, Mount Pleasant, Iowa; Keokuk Medical College, College of Physicians and Surgeons, 1903; member of the American Medical Association; died June 18, aged 71, of chronic nephritis.

Reuben Terrell McCraw ⊕ Oxford, Ala.; University of Alabama School of Medicine, 1913; died in the Anniston Memorial Hospital, Anniston, June 9, aged 58, of coronary thrombosis.

Carl Raymond Madera, Upper Darby, Pa.; Hahnemann Medical College and Hospital, Philadelphia, 1933; member of the American Medical Association; died in the Hahnemann Hospital July 4, aged 47, of pneumonia.

Joseph James McGarry ⊕ North Tarrytown, N. Y.; Fordham University School of Medicine, New York, 1918; member of the American Society of Anesthetists; police surgeon; on the staff of the Tarrytown Hospital, where he died June 30, aged 51, of carcinoma of the lung with metastasis to the vertebrae.

Stephen Eugene McKenna ⊕ Los Angeles; University of California Medical School, San Francisco, 1937; formerly an intern at the Orange County Hospital in Orange, Calif.; resident in surgery at the Queen of Angels Hospital; served overseas during World War II; died June 16, aged 37, of bulbar poliomyelitis.

Archibald Carlyle McPhaden, Concrete, Wash.; Bennett Medical College, Chicago, 1911; member of the American Medical Association; on the staff of the Memorial Hospital in Sedro Woolley; died June 28, aged 63, of acute coronary occlusion.

Rudolph Manns ⊕ Denver; Gross Medical College, Denver, 1900; for many years surgeon for the Colorado and Southern Railway Company; member of the staffs of St. Joseph's, St. Luke's, Mercy, Children's, Presbyterian and National Jewish hospitals; died recently, aged 71, of coronary occlusion.

Joseph Hyman Marko, Cleveland; University of Virginia Department of Medicine, Charlottesville, 1946; interned at the Mount Sinai Hospital; killed in the crash of a DC4 airliner in the Blue Ridge mountains of Virginia June 13, aged 24.

John Tracy Melvin ⊕ Porterville, Calif.; Gross Medical College, Denver, 1891; an Affiliate Fellow of the American Medical Association; formerly affiliated with the Indian Service; served as president of the Tulare County Tuberculosis Association and as director of the board of the California State Tuberculosis Association; at one time medical director of the Tulare-King Counties Joint Tuberculosis Hospital in Springville; formerly member of the Colorado State Board of Health; died June 21, aged 85.

William Edwin Miller, Camden, N. J.; University of Pennsylvania Department of Medicine, Philadelphia, 1893; died in the Cooper Hospital June 30, aged 74, of fracture of the eleventh thoracic vertebra and arteriosclerosis.

William C. Mitchell, Tunbridge, Vt.; University of Vermont College of Medicine, Burlington, 1907; served as health officer; affiliated with the Veterans Administration Hospital in White River Junction; died June 20, aged 66, of pulmonary edema and chronic endocarditis.

David Bruce Moyer ⊕ Lansdale, Pa.; Medico-Chirurgical College of Philadelphia, 1908; died June 25, aged 64, of coronary occlusion.

Harold Gert Muller ⊕ Cato, N. Y.; Schlesische-Friedrich-Wilhelms-Universität Medizinische Fakultät, Breslau, Prussia, 1934; served overseas during World War II and was awarded the Bronze Star Medal for bravery; affiliated with the Lee Memorial Hospital in Fulton and the City Hospital in Auburn; died in the City Hospital, Syracuse, June 27, aged 38, of mumps and encephalitis.

George A. Nickelson, Pittsburgh; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1902; died June 24, aged 72.

Charles Henry Pate, Scranton, S. C.; Medical College of the State of South Carolina, Charleston, 1904; died June 26, aged 66, of bronchopneumonia, cerebral hemorrhage and diabetes mellitus.

Edward Cornelius Perry, Avon, N. Y.; Columbia University College of Physicians and Surgeons, New York, 1892; past president and treasurer of the Livingston County Medical Society; for many years county coroner, village health officer and surgeon for the Erie Railroad; died June 30, aged 81, of prostatic carcinoma.

Malcolm Hay Phillips, Pittsburgh; University of Pittsburgh School of Medicine, 1908; died in St. John's General Hospital recently, aged 61, of influenza, pneumonia and coronary artery disease.

Louis George Reynolds, Los Angeles; Northwestern University Medical School, Chicago, 1908; died in the Cedars of Lebanon Hospital June 22, aged 76.

William Clyde Roberts, Tallahassee, Fla.; the Hahnemann Medical College and Hospital, Chicago, 1906; at one time assistant medical director of the New York Life Insurance Company in New York; died June 22, aged 65, of congestive heart failure and essential benign hypertension.

Lee Rose, Carpenter, Ky.; Lincoln Memorial University Medical Department, Knoxville, 1914; member of the American Medical Association; chairman of the county board of education; served during World War I: shot and killed July 1, aged 61, by cattle thieves.

Oscar Leo Rudersdorf, Evanston, Ill.; Bennett Medical College, Chicago, 1912; member of the American Medical Association; affiliated with St. Francis Hospital; died June 28, aged 58, of coronary occlusion.

John William Sherman ⊕ Mirando City, Texas; Medical Department of Grant University, Chattanooga, Tenn., 1906; died in Miami, Fla., June 19, aged 60, of coronary thrombosis.

Allie Marion Stuart, Manning, Ark. (licensed in Arkansas in 1903); died May 14, aged 66.

William Sweemer ⊕ Milwaukee; College of Physicians and Surgeons of Chicago, 1884; an Affiliate Fellow of the American Medical Association; served as emeritus professor of diseases of children at the Milwaukee Medical College, of which he had been a founder; died June 21, aged 93, of senility.

Harry French Thompson, Forest City, Iowa; Rush Medical College, Chicago, 1894; member of the American Medical Association; past president of the Winnebago County Medical Society; died June 17, aged 77, of coronary occlusion.

Charles Root Turner, Philadelphia; University College of Medicine, Richmond, 1899; served as dean of the University of Pennsylvania School of Dentistry; died in a hospital at Raleigh, N. C., June 11, aged 71.

Benjamin Van-Sant, Turbotville, Pa.; Jefferson Medical College of Philadelphia, 1890; died June 16, aged 83, of chronic myocarditis.

Capt. Myer H. Boyarsky
M. C., A. U. S., 1917-1945

Howard Lull Van Winkle ⊕ Cedar Rapids, Iowa; Long Island College Hospital, Brooklyn, 1907; past president of the Linn County Medical Society; at one time affiliated with the New York State Board of Health in Albany and on the faculty of the Syracuse University College of Medicine in Syracuse, N. Y.; served during World War I; on the staffs of the Mercy Hospital and St. Luke's Methodist Hospital; died June 22, aged 64, of carcinoma of the pancreas.

Leroy Powell Van Winkle ⊕ Port Jefferson Station, L. I., N. Y.; Long Island College Hospital, Brooklyn, 1903; member of the American College of Radiology; specialist certified by the American Board of Radiology; consulting roentgenologist at the Huntington Hospital in Huntington and the Greenpoint Hospital in Brooklyn; visiting roentgenologist at the Central Islip State Hospital in Central Islip, John T. Mather Memorial Hospital and St. Charles Hospital for Crippled Children; died June 8.

Frank S. Vernon, Charleston, Mo.; Missouri Medical College, St Louis, 1893; served as coroner and county physician; formerly on the staff of the State Hospital in Farmington; died June 28, aged 76, of heart disease.

Heilman Curtis Wadsworth, Washington, Ind.; Rush Medical College, Chicago, 1909; member of the American Medical Association; councilor of the Second District of the Indiana State Medical Association; served during World War I; died June 6, aged 68.

Marcus Fitzherbert Wheatland Jr., Camden, N. J.; Howard University College of Medicine, Washington, D. C., 1927; member of the American Medical Association; died in the University of Pennsylvania Hospital, Philadelphia, June 7, aged 48.

Herbert Temple Wikle ⊕ Brooklyn; Vanderbilt University School of Medicine, Nashville, Tenn., 1919; assistant clinical professor of surgery at the Long Island College of Medicine; fellow of the American College of Surgeons; past president of the Brooklyn Surgical Society and the New York Gastroenterological Society; on the staffs of Cumberland Hospital, Methodist Hospital and the Brooklyn Hospital, where he died June 26, aged 53, of coronary thrombosis.

Alexander Woodward Winkler ⊕ New Haven, Conn.; Harvard Medical School, Boston, 1931; assistant professor of medicine at the Yale University School of Medicine; diplomate of the National Board of Medical Examiners; specialist certified by the American Board of Internal Medicine; member of the American Society of Clinical Investigation; on the staff of the New Haven Hospital, where he died June 26, aged 38, of hypertensive cardiovascular disease.

Capt. Vladimir M. Sasko
M. C., A. U. S., 1914-1945

George Roy Wiseman, Amherst, Ohio; Ohio Medical University, Columbus, 1900; served overseas during World War I; on the staff of St. Joseph's Hospital in Lorain; died June 20, aged 69, of coronary heart disease.

Edward W. Yates, Foreman, Ark. (licensed in Arkansas in 1929); member of the American Medical Association; died July 11, aged 47.

KILLED IN ACTION

Myer Harold Boyarsky, Burlington, Vt.; University of Vermont College of Medicine, Burlington, 1942; diplomate of the National Board of Medical Examiners; interned at St. Luke's Hospital in New Bedford, Mass.; began active duty as a first lieutenant in the medical corps, Army of the United States, on July 31, 1943; later promoted to captain; regimental surgeon of the 47th Infantry Regiment, 9th Division; received the Purple Heart, the Bronze Star and the Silver Star; killed in action in Germany April 19, 1945, aged 27.

Vladimir Molnar Sasko, Chicago; the School of Medicine of the Division of Biological Sciences, Chicago, 1938; interned at the University of Chicago Clinics and the City Hospital in Cleveland; began active duty as a first lieutenant in the medical corps, Army of the United States, July, 1, 1941; promoted to captain; on Dec. 10, 1944 en route by plane from Dobodura, New Guinea, to Hollandia, plane failed to arrive at its destination for reasons unknown; presumed dead in the Southwest Pacific Dec. 11, 1945, aged 31, by the War Department.

The Early Diagnosis of Poliomyelitis

At the present rate of notification of poliomyelitis 5,000 cases are expected before the end of the year, which is much in excess of any previous year since the disease became notifiable in 1912. At a special meeting of some 80 health officers a number of procedures for dealing with the outbreak were recommended. Swimming baths should not be closed unless there are some definite indications that patients may have been infected there. But the number of children admitted on any one day should be restricted, and they should be advised to stay in the baths for only a short period. Overcrowding is probably a more important factor than infection of the water. Hired bathing suits and towels should be washed and laundered before reuse. Schools should reopen as usual unless there are special indications to the contrary. Nursery schools and day nurseries should be closed on the occurrence of the first case. The chances of the spread of the virus there are regarded as greater than in ordinary schools. Children and adolescents who have been in contact with a patient should be warned to keep away from other children and young persons for three weeks.

Poliomyelitis Film for the Instruction of Physicians

Because of the importance of early diagnosis and the fact that few physicians have had an opportunity to see patients in the early preparalytic stage, the Ministry of Health has had a short film on the early diagnosis of poliomyelitis prepared. The British Medical Association has arranged to assist in distributing copies of the film and to have it shown at the meetings of the divisions of the association. By the end of the month there should be a hundred copies of the film ready for distribution. A chart of the age incidence is followed by symptoms. An effective scene shows the early restlessness of the young adult. A feature of this epidemic has been early involvement of the cranial nerves, and an outstanding close-up shows a palate with just enough weakness on the left to be pulled slightly toward the right. Other signs of the disease are demonstrated. Finally, simple measures to prevent the spread of infection are shown. The running time is only fifteen minutes. The latest figures, just announced, show that for the week ending August 16 646 cases of poliomyelitis were reported in England and Wales, compared to 448 and 568 in the weeks ending August 2 and 9. London had 89 notifications, Birmingham 18 and Manchester 15 for the week ending August 16. The total for that week was the largest in the epidemic.

Midwifery Under the National Health Service Act

The Minister of Health has issued a guide to local health authorities on their duties under the National Health Service Act. In the maternity service every woman will be entitled to a family physician, whom she will probably consult when she believes that she is pregnant. Subject to regulations which have yet to be made, it is contemplated that every general practitioner will be given an opportunity to say whether or not he desires to practice midwifery under the act and to answer calls by midwives for medical aid. The experience of practitioners who desire to do so will be reviewed by a local committee of a wholly professional character (consisting of local general practitioners, a consultant obstetrician and local authority's health officer). This committee will draw up a list of approved local practitioners and indicate to those who are not accepted for such a list the need for further obstetric experience. The list will be reviewed from time to time to insure that the physicians on it continue to undertake enough midwifery to remain competent. The duty of a family physician when consulted by a woman who is pregnant will be to see that she knows how to obtain the services of a midwife; if he himself is not on the approved list he will help the woman to choose a general practitioner obstetrician from the list. The physician selected will give her the necessary antepartum and postpartum care and will be present at the confinement if he considers it necessary or is called by the midwife.

Outbreak of Smallpox

An epidemic of smallpox broke out at the beginning of this year. The epidemiologic investigation established that the infection was brought into the city in December 1946 by a patient from Liège, Belgium, where an epidemic prevailed. During December and January some unrecognized cases of severe smallpox must have occurred in Paris; between February 10 and March 30, 33 cases, 2 of which were fatal, had been observed. The epidemic seems to have been confined to the Claude-Bernard, Salpétrière and St. Louis hospitals. It was of the alastrim form and spread among unvaccinated children and among adults either not recently vaccinated or vaccinated without a positive effect. Strict measures of isolation and vaccination have been taken. Vaccinations were extended to inhabitants of buildings where the disease had appeared and neighboring buildings. On advice of the Superior Council of Public Hygiene, the members of the hospitals' staffs, the inpatients and outpatients and the visitors were vaccinated as well as those in the Institutions of the Paris District, all nurslings from the first month onward, school children and persons in homes for the aged and the incurable. Centers for gratuitous vaccination were opened in every quarter of town. In Paris 292,787 vaccinations were performed between March 11 and April 30 by the Service of the Seine District Prefecture. One million vaccinations were performed in the Seine district. Thanks to these measures, the epidemic soon subsided. The only complications arising from the numerous vaccinations were the deaths of 2 children given their first vaccination, 1 of whom died of bronchopneumonia. It has also been found that a postvaccinal complication may arise when, for some reason or other, the vaccine penetrates into the blood circulation. R. Boulain, P. Uhry and Gueniot have vaccinated 33 diabetic persons which, they explained at a meeting of the Medical Society of the Paris Hospitals, brought about an aggravation of diabetes in 7 patients. It is of interest that, at the same time, epidemics of variola were reported in Liège and in the British port of Grimsby. Several cases also occurred in Germany, Spain, Portugal, Italy and New York.

Congress of French-Speaking Pediatricians

The first postwar meeting of French-speaking pediatricians was held in Lyons under the presidency of Professor G. Mouriquand; three hundred French pediatricians and numerous Belgians, Luxemburgers, Dutch, Portuguese, Swiss and Czechoslovaks took part.

Nontuberculous Meningitis of Children.—R. Martin, B. Sureau and A. Milet pointed out that sulfonamide drugs in the treatment of meningococcic meningitis of children bring about 92 per cent of recoveries. In recurrent cases and in nurslings they add to the sulfonamide therapy the use of penicillin. **R. Clement'** observations on 50 cases of acute meningitis, half tr
with sulfonamide drugs only and the oth
bined penicillin and sulfonamide compo

results obtained by the foregoing practitioners. If the general condition and the temperature of the nursling does not improve, Clement performs ventricular paracentesis, followed by an injection of penicillin as early as the second day of the disease. Lelong, R. Joseph, A. Rosier and F. Alison were equally in favor of ventricular paracentesis with an early injection of penicillin. Pneumococcic meningitis, notwithstanding the combined sulfonamide-penicillin therapy, has still a 50 per cent death rate. R. A. Marquezy and Boeswilwald reported their observations on 19 cases of pneumococcic meningitis; of 10 patients treated with only sulfonamide drugs, there were 10 deaths; of 9 patients given sulfonamide-penicillin therapy, 4 recovered. They emphasized the value of early treatment; in nurslings they perform intraventricular injections at the rate of at least two each day (20,000 Oxford units). However, despite the continuation of local penicillin therapy, in 2 cases they have seen the pneumococci reappearing in the cerebrospinal fluid on the sixteenth and the twenty-first day. For the treatment of meningitis due to Hemophilus influenzae E. Gorter (Leyde) proposed intramuscular and intrarachidian injections of streptomycin, complemented, in extremely serious cases, with sulfadiazine, penicillin and, if possible, rabbit antiserum.

Chronic Rheumatic Infections of Children.—M. Lamy, Miss M. Jammet and M. Aussanaire have explained that chronic rheumatic manifestations, whatever be their type, certainly are ascribable to an undetermined infectious process. In the ankylotic form, with osteoarticular lesions, death, according to these authors, occurs after a few years; the prognosis of Still's disease (multiple rheumatoid arthritis) is also bad. To the contrary, R. Clement's observations revealed that, of 6 cases of the latter form, kept under observation for years, 3 lead an almost normal life after cures by sulfonamide therapy, which brought the sedimentation rate back to normal; the fourth case made a spontaneous recovery twelve years ago, after failure of all treatments. In his study of 295 patients kept under observation for ten years, R. Lesne has come to the conclusion that the chronic rheumatism of children is never the sequela of Bouillaud's disease (rheumatic fever). G. Mouriquand and G. Wenger (Lyons) have noted the lasting improvement of the pain by means of parathyroidectomy in a case of chronic rheumatism deformans after failure of treatment by calcium, ascorbic acid and vitamin D. L. Willemin-Clog (Clermont-Ferrand) has insisted on the therapeutic effect of immobilization and of orthopedic apparatuses in chronic rheumatism deformans.

Sept. 7, 1947.

The D. P. Disease

The name D. P. disease was chosen by P. Robinson for a complex of symptoms which he observed in a number of patients in the Allied Commission camps in Italy. In his paper in the *Acta Medica Orientalia* (**6**:188, 1947) he reports on the symptomatology. From 37 cases under observation the following histories were given almost unanimously: The patients felt fairly well as long as they were in concentration camps or with the partisans. Some suffered from angular stomatitis with or without photophobia and blurred vision. Some had night blindness. Others were suffering from edema, partly with peripheral neuritis. The first signs of stomach-intestine trouble appeared immediately after the patients had come to the UNRRA or AC camps. The main complaints were fulness and pressure in the stomach immediately after meals and a feeling of burning or pains late at night. The complaints were alleviated during the intake of food. Ocular trouble was present in a number of cases, and circumcorneal injections were sometimes found to be the cause. Otherwise, the physical examination showed normal results. Tests of the digestive juice revealed in all cases a complete achlorhydria. When roentgen examination of the stomach was done, delayed emptying of the stomach was always found.

From these symptoms the clinical suspicion of ariboflavinosis seemed justified. Administration of riboflavin was usually not successful. Only large doses of liver extract given over prolonged periods achieved definite and lasting improvement, and when the therapy was continued a complete cure resulted.

Two patients were operated on, their stomach trouble giving ground to the belief that they were suffering from gastric ulcers. During the operations, however, it was determined that ulcers did not exist but there was an atrophic gastritis. This atrophic gastritis is well known for its favorable reaction to liver therapy.

In summary Robinson states that the D. P. disease is an atrophic gastritis combined with vitamin B deficiency.

Palestine Society for Medical History

The opening session of the Palestine Society for Medical History took place in April 1947. Leading physicians of the country participated. In his opening address Dr. S. Muntner stressed the necessity and the aims of a Society for Medical History. Lectures held during the first session included, among others, a report by Dr. Sherman, president of the Association of Jewish Physicians in Palestine, on the "History of Jewish Medicine in Palestine during the Past Century." Professor Feigenbaum reported on "Medical Nomenclature, Considering in Particular the Ophthalmologic Terms in the Talmud."

In the first pamphlet published by the Palestine Society for Medical History, the tasks set for the society are sketched, and it is mentioned that shortly a series of publications will appear, which will be devoted to the history of Jewish medicine. The first book of this series, the "Book of Medicine" by Assaf, is already going into print. The reference to the first book written in Hebrew by R. Shabbatai Dolono in Christian Europe is of special importance within the frame of the newly founded Society for Medical History, since it was written in Salerno, Italy, exactly a thousand years ago. The foundation of the medical faculty of the Hebrew University in Jerusalem coincides with the thousandth anniversary of Jewish medicine in Europe.

Medical Department of the Jewish National and University Library

In July the new medical library was opened in the Medical School of the Hebrew University, the Nathan Ratnoff building. The medical library, previously part of the general library of the university, has thus obtained a room of its own, easily accessible to all research men and scholars working in the Medical School of the Hebrew University or in the Hadassah Hospital. The opening ceremony was led by Dr. Jaski, head of the Hadassah University Hospital. He pointed out the merits of two physicians who paved the road toward the success now achieved: Dr. Julius Jarcho, New York, a benefactor of the medical library system in Palestine, and Dr. Emanuel Libman, whose connections with the medical world of Palestine are known. A third physician who should have been mentioned is Dr. Joseph Chasanowitz, who more than fifty years ago in Russia conceived the idea of a great university library in Jerusalem, and who realized his idea in decades of struggling and collecting.

The director of the Jewish National and University Library, Dr. Joel, referred to the great difficulties caused by this new project, but he also pointed out how carefully the new library was equipped by the administration of the university and how it will be utilized in the future.

The medical library comprises, at present, about 22,000 books. In cooperation with the committee of the Jewish Medical Association, under Dr. Doljanski, the medical library was arranged in its new rooms with excellent taste. One reading room contains all the medical magazines and periodicals of the University library and has a selected hand library with more than three hundred current periodicals from all over the world.

Dr. Wallach has been placed in charge of the medical library.

MOSCOW

(From Our Regular Correspondent)

Aug. 19, 1947.

The Sixth All-Union Congress of Pediatricians

In Moscow from May 27 to June 1, 1947 the Sixth All-Union Congress of Pediatricians was held, the first since the war. About 1,800 pediatricians were present Professor George N. Speransky, corresponding member of the Academy of Sciences of the U. S. S. R., member of the Academy of Medical Sciences, was president-elect of the congress. The first meeting was devoted to the memory of the founder of Russian pediatrics, Professor Nil F. Filatov, in connection with the centenary of his birth.

Mary D. Kovrigina, Deputy Minister of Health of the Soviet Union, in opening the congress noted that in 1947 about 25 per cent of all sums granted for public health care—4 billion rubles (about 755 million dollars)—have been given to expenditures for children's and maternity health protection. There are in the Soviet Union more than 18,500 pediatricians, not including 12,000 physicians of rural areas working on children's health and many thousands of medical nurses and teachers.

Nutritional disturbances especially in young children was one of the topics discussed. The principal thesis of Professor Mikhail S. Maslov's report was that the disturbances of children's nourishment resulting from different diseases may be seen simultaneously with symptoms of "toxicosis" and various septic processes. Dystrophy, "toxicosis" and sepsis may successively pass one into another. A young child, even if healthy, is not resistant enough to the action of toxins; all his regulative systems—reticulocytic, endothelial, fermentative and vitamin systems, hemoparenchymatous and hemoencephalic barriers—are insufficient. The endocrine and vegetative portions of the nervous system cannot at this age regulate all the functions because they are not developed completely. The maintenance of the normal condition of the child's organism depends on early diagnosis.

Professor Julia F. Dombrovskaya spoke on alimentary disturbances. The principal diseases of the undernourished child in early infancy are pneumonia and digestive diseases; in the preschool and school age, cardiovascular diseases and endocrine and vegetative disturbances. The initial digestive impairments result in disturbances of gastric secretion, i. e., hypochlorhydria, hyperchlorhydria or achlorhydria. Later disturbances of absorption and digestion may be present. The stool becomes enriched with neutral fats and fatty acid salts—signs of unbalanced hepatic function, according to Professor Speransky.

Professor Nicolas A. Krasnogorsky, member of the Academy of Medical Sciences, noted that alimentary and digestive disturbances in young children reduce the efficiency of the central nervous system. Cerebral and cortical excitability diminish, and the correlation between cortical and subcortical activity becomes delayed. Simultaneously, disturbances of cerebral and endocrine origin are observed, such as anorexia, polyuria and excessive thirst. Hypothyreosis may be present. Sometimes after prolonged dystrophy real endocrine disturbances such as hypophysial dwarfism and hypogenitalism may take place. Cardiovascular disturbances are also present—fall of blood pressure, dilatation of the right auricle and impairment of the pulse rhythm and frequency.

Professor Olga D. Sokolova-Ponomareva from the Omsk (Siberia) Medical Institute, corresponding member of the Academy of Medical Sciences, reported on "Blood Transfusion as a Curative Method for Young Children." On the basis of 6,000 blood transfusions she demonstrated its positive effect on the red blood cells, albumin and ferment contents and the result and improvement of the circulation, including capillaries.

Professor Alga P. Molchanova spoke on the significance of albumins and mineral substances in children's nutrition. Milk is the principal source of albumin for the child, containing in best physiologic proportions calcium, phosphorus and other valuable substances. Assistant doctor Sophy A. Bajandina reported on "Immunity Readings During Infectious and Septic Processes in Infants." She demonstrated that the maternal unboiled freshly drawn breast milk gives the best results in the treatment of nurslings' diseases, especially pneumonia and sepsis.

Professor Vera A. Krestovnikova reported that she discovered in the nasopharynx of newborn children with infectious diseases a predominance of hemolytic streptococci. In her opinion the nasopharynx is the primary nidus and entrance for toxic diseases. Dr. I. A. Stern, on the basis of Professor Krestovnikova's bacteriologic observations, divides the diseases of newborn into three principal groups: (1) acute diseases of the respiratory tract (nasopharyngitis, pneumonia and influenza), (2) septic purulent diseases and (3) infectious toxic diseases with entrance in the nasopharynx. Dr. Stern used for their prophylaxis a staphylococcic vaccine with good results.

One meeting was devoted to the etiology, pathogenesis and clinical course of pneumonia in infants, prematurely born infants and children of early age.

Prof. Mikhail A. Skvortsov stated that interstitial pneumonias often arise in the course of septic diseases. Their characteristic properties are an absence of exudate in the bronchi and alveoli simultaneously with large infiltrative and proliferative changes in alveolar and interlobar septums and in the peribronchial cellular tissue. Clinically the interstitial pneumonia is characterized by a rapid attack of cyanosis and by difficult breathing.

Interesting data were presented by the Kiev University docents D. L. Segalov and I. A. Maximovich. They differentiated two types of pneumonias in the case of infants with disturbed alimentation: (1) a usual reactive pneumonia and (2) an asymptomatic dysergic form. This differentiation is based on clinical observations of the course of the disease and on histologic study.

Professors E. I. Kvater and S. A. Jagunov in their reports, "Contact Work Between Obstetricians and Pediatricians" and "Rational Newborn Service," turned the congress' attention to the need for careful work of both types of specialists, especially in questions of correct lactation, preparation of the mammary gland for feeding, prophylactic measures against mastitis, report of the effect of obstetric operations on the newborn and of the significance of acute infectious diseases on the future sexual development of girls.

More than eighty reports were presented at the congress. In the Soviet Union there exist fifteen state scientific investigatory institutes for maternal and child welfare. This year for the work of only three principal institutes 29 million rubles (about $5,500,000) are granted. There are sixty-two pediatric clinics as departments of medical institutes with a total of more than one thousand specialists and scientific workers in pediatrics. There are also fifty scientific pediatric societies.

In closing the congress Professor George N. Speransky, the president, urged its members to creative work to solve great problems of Soviet pediatrics, emphasizing the role of scientific societies in the development of the correct mode [illegible]diatric thought.

Correspondence

THE STABILITY OF PROTHROMBIN

To the Editor:—The recent current comment on Stability of Prothrombin in THE JOURNAL, September 9, page 36, contains certain statements to which I am compelled to take exception; particularly to one: "Unreliable values for prothrombin obtained by the one stage method etc." It might be well to inquire concerning the actual facts. In 1943 I reported in the *American Journal of Physiology* (**140**:212 [Nov.] 1943) my discovery that the delayed prothrombin time in stored plasma was due to the disappearance of a factor which was different from the prothrombin principle, which is reduced in "dicumarol" poisoning and which is adsorbable by aluminum trihydroxide, $Al(OH)_3$. From these results I concluded that prothrombin was a complex and that one of the components was this labile factor whose activity was slowly diminished in stored plasma by oxidation. Recently Owren (*Lancet* **1**:446 [April 5] 1947) reported a case in which the bleeding tendency appears definitely to be due to a lack of this factor. That this factor is missed in the analysis of stored plasma by the more elaborate two stage method is probably accounted for by the possibility that the thromboplastin employed (beef lung) contains sufficient quantity of the labile factor as an impurity to mask the defect in the highly diluted plasma.

By means of my one stage method I have discovered two families in each of which several members have a congenital hypoprothrombinemia; but, curiously, the factor deficient in the one family is different from the one lacking in the second family (*Lancet* **2**:379 [Sept. 13] 1947). The concentration of the labile factor is normal in the affected members of both families. This clearly suggests that the prothrombin activity as indicated by the prothrombin time of the one stage procedure is dependent on three factors. A diminution of any one of these three factors sufficient to increase the prothrombin time to 20 second (in human beings) appears to produce a bleeding tendency. Since the test of prothrombin time, when carefully and correctly performed, has a sensitivity so delicate that a variation of only 2 or 3 seconds marks the difference between normal hemostasis and a hemorrhagic diathesis, it seems high time to stop quibbling about the theoretic reliability of the one stage method and to concentrate on having the test carried out correctly and accurately (according to my specific directions) in both the clinical and the research laboratories, thereby putting an end to the abominable confusion concerning prothrombin values which is rampant at present.

CAVERNOUS SINUS THROMBOSIS

To the Editor:—In an article entitled "Cavernous Sinus Thrombosis" by Samuel L. Fox and J. Brooks West published in THE JOURNAL, August 23, the authors say on page 1454: "A careful review of the literature by us fails to reveal any report of a case in which 'dicumarol' was employed, with or without other agents, so that the use of this drug in 1 of our cases may well represent its earliest use in treatment of this condition."

In an article entitled "A Case of Cavernous Sinus Thrombosis Successfully Treated by Combined Anticoagulant and Chemotherapy," which was published in the *Annals of Internal Medicine* (**24**:1093 [June] 1946) we state on page 1095 that this patient was treated with "dicumarol."

PROPHYLAXIS AGAINST OPHTHALMIA NEONATORUM

To the Editor:—At the June session of the American Medical Association this year, I presented a resolution before the Section on Ophthalmology condemning the use of silver nitrate and urging its replacement by antibiotics in the prevention of ophthalmia neonatorum. A copy of this resolution was published in THE JOURNAL July 5.

In the August 9 issue of THE JOURNAL there appears an important publication entitled "Prophylaxis Against Ophthalmia Neonatorum" by H. Charles Franklin of Memphis, Tenn. This report is a comparison of the efficacy of penicillin compared with silver nitrate. Although this piece of research work has many weak points, it emphasizes the beginning of the end of silver nitrate in the prevention of ophthalmia neonatorum. Like most clinicians, Dr. Franklin seeks to point out the fallacy which most of us have glorified since the year 1884, that one drop of any chemical can stop the growth of any pathogenic organism. Ophthalmologists, particularly those in Philadelphia, have discovered that the efficacy of silver nitrate is in the use of irrigating solutions, principally salt solution and boric acid. Keeping in mind that the silver served only as a silver lining of imagination, the mechanical flushing of the eyes actually accomplished the prevention of the disease.

Credé originally emphasized the cleansing of the birth canal, using silver nitrate in the babies' eyes only as a secondary thought. Through the years both the obstetricians and the ophthalmologists forgot completely about the source of infection, namely the birth canal, and found it convenient to believe in the safety of one drop of silver nitrate in the eyes of the newborn. It seems short of folly for physicians to use silver nitrate today in lieu of the effectiveness of antibiotics.

It is unscientific to treat or prevent any disease except at its sources. It is my contention that the babies' eyes should receive no preventive treatment whatever. Emphasis should be placed on partial sterilization of the birth canal for at least twenty-four hours before delivery. This can be accomplished by the use of penicillin vaginal suppositories or by the parenteral use of penicillin, using a single dose of 300,000 units in oil. It is rightly believed that the vaginal tract cannot be completely sterilized. It is not necessary to sterilize the vaginal tract completely before delivery. Approximately 98 per cent of all babies would escape infection even if 100 per cent of the mothers were infected with pathogenic organisms. In other words, there is a natural safety of 98 per cent by natural means. It is not necessary to put irritating chemicals in the eyes of all newborn babies in order possibly to save infection of the other 2 per cent. It is my personal experience that all cases of gonorrheal ophthalmia in the newborn can be positively cured in a few days. There is no need for a single case of blindness to result. A decade ago, practically all cases of ophthalmia neonatorum required weeks of treatment and in almost every case some damage to the eyes was noted. The baby world is free from this danger in the antibiotic period.

The prevention of ophthalmia neonatorum should be directed to the treatment of the infected expectant mother by the use of antibiotics, and the eyes of the newborn should receive no treatment whatever. Should an occasional case of infection in the newborn develop, penicillin will cure it.

I have not mentioned the many organisms responsible for ophthalmia neonatorum. There is only one damaging organism and that is the gonococcus. Cases of infection from other organisms do not result in blindness. Since the gonococcus can be controlled by antibiotics, the prevention of ophthalmia neonatorum of the future must be directed to the expectant mother alone.

Medical Examinations and Licensure

COMING EXAMINATIONS AND MEETINGS

NATIONAL BOARD OF MEDICAL EXAMINERS EXAMINING BOARDS IN SPECIALTIES

Examinations of the National Board of Medical Examiners and the Examining Boards in Specialties were published in The Journal, Sept. 27, page 246.

BOARDS OF MEDICAL EXAMINERS

Alabama: *Examination.* Montgomery, June 22-24, 1948. Sec., Dr. D. G. Gill, 519 Dexter Ave., Montgomery 4

Arizona: * *Examination.* Phoenix, Oct 7-8 Sec., Dr. J. H. Patterson, 826 Security Building, Phoenix.

Arkansas: * *Examination.* Texarkana, Nov 6-7, 1947. Sec., L. J. Kosminsky. Texarkana. *Eclectic.* Little Rock, Nov. 6. Sec., Dr. Clarence H. Young, 1415 Main St., Little Rock

California: *Written.* Sacramento, Oct. 20-23. *Oral.* Los Angeles, Nov. 8-9. Sec., Dr. Frederick N. Scatena, 1020 N St., Sacramento 14.

Connecticut: *Examination.* Hartford, Nov 11-12. Sec., Dr. Creighton Barker, 258 Church St., New Haven.

Delaware: *Examination.* Dover, Jan 13-15 *Endorsement.* Dover, Jan. 20. Sec., Dr. J. S. McDaniel, 229 S. State St., Dover.

Florida: * *Examination.* Jacksonville, Nov 25-26. Sec., Dr. Harold D. Van Schaick, 6675 Windsor Lane, La Gorce Island, Miami.

Georgia: Atlanta, Oct. 14-16. Sec., Mr. R. C. Coleman, 111 State Capitol, Atlanta, 3.

Hawaii: *Examination.* Honolulu, Ja [illegible], 1948. Sec., Dr. S. E. Doolittle, 881 S. Hotel St., Honolulu, T. H.

Idaho: Boise, Jan. 13-15. Sec., Miss [illegible] S. Mulliner, 355 State Capitol Bldg., Boise.

Illinois: Chicago, Oct. 14-16. Supt. of Registration, Dept. of Registration and Education, Mr. Philip M. H[illegible] Springfield.

Indiana: *Examination.* Indianapolis, J[illegible]-18 Sec., Board of Medical Registration and Examination, Dr. Paul R. Tindall, K of P Bldg., Indianapolis.

Kansas: Topeka, Dec. 3-4. Sec., Board of Medical Registration and Examination, Dr. J. F. Hassig, 905 N. 7th St., Kansas City.

Maine: * Portland, Nov. 12-13. Sec., Dr. A. P. Leighton, 192 State Street, Portland.

Maryland: *Medical Examination.* Baltimore, Dec. 9-12. Sec., Dr. Lewis P. Gundry, 1215 Cathedral St., Baltimore. *Homeopathic. Examination.* Baltimore, Dec. 9-10. Sec., Dr. J. A. Evans, 612 W. 40th St., Baltimore.

Massachusetts: *Examination.* Boston, Nov. 18-21. Sec., Dr. H. Q. Gallupe, 413-E State House, Boston.

Michigan: * *Examination.* Lansing, Nov [illegible] Sec., Board of Registration in Medicine, Dr. J. E. McIntyre, 100 W. Allegan St., Lansing 8.

Minnesota: * Minneapolis, Oct. 21-23. Sec., Dr. J. F. DuBois, 230 Lowry Medical Arts Bldg., St. Paul 2.

Mississippi: *Endorsement.* Jackson, Dec. 1947 Asst. Sec., State Board of Health, Dr. R. N. Whitfield, Jackson.

Missouri: *Examination.* St. Louis, Oct. 20-22 Exec. Sec., Mr. John A. Hailey, State Capitol Bldg., Jefferson City.

Montana: Helena, Oct. 6-8. Sec., Dr. O. G. Klein, First National Bank Bldg., Helena.

Nevada: Carson City, Nov. 3. Sec., Dr. G. H. Ross, 215 N. Carson St., Carson City.

New Jersey: *Examination.* Trenton, Oct. 21-22. Sec., Dr. E. S. Hallinger, 28 W. State St., Trenton.

New Mexico: * Santa Fe, Oct. 13-14. Sec., Dr. LeGrand Ward, 141 E. Palace Ave., Santa Fe.

New York: *Examination.* Albany, Buffalo, New York and Syracuse, Oct. 6-9, 1947. Sec., Dr. Jacob L. Lochner, Jr., Education Bldg., Albany.

North Carolina: *Endorsement.* Raleigh, Oct. 20. Act. Sec., Mrs. L. J. McNeill, 226 Hillsboro St., Raleigh.

North Dakota: Grand Forks, Jan. 6-9. Sec., Dr., G. M. Williamson, 4½ S. Third St., Grand Forks..

Ohio: *Examination.* Columbus, Oct. 14. *Endorsement.* Columbus, Dec. 2-4. Sec., Dr. H. M. Platter, 21 W. Broad St., Columbus.

Oklahoma: *Endorsement.* Oklahoma City, Oct. 28-29. Sec.; Dr. F. Clinton Gallaher, 813 Braniff Bldg., Oklahoma City.

Oregon: * *Endorsement.* Portland, Oct. 17-18. Exec. Sec., Miss L. M. Conlee, 608 Failing Bldg., Portland.

Pennsylvania: *Examination.* Harrisburg, Jan. 1948. Acting Sec., Board of Medical Education and Licensure, Mrs. M. G. Steiner, 351 Education Bldg., Harrisburg.

South Carolina: Columbia, Nov. 10-12. Sec., Dr. N. B. Heyward, 1329 Blanding St., Columbia.

South Dakota: * Pierre, Jan. 20. Sec., State Board of Health, Dr. Gilbert Cottam, Capitol Bldg., Pierre.

Texas: San Antonio, Nov. 12-14, 1947. Sec., Dr. T. J. Crowe, 918-20 Texas Bank Bldg., Dallas 2.

Utah: *Reciprocity.* Oct. 8. *Examination.* Salt Lake City, June, 1948. Asst. Dir., Department of Registration, Miss Rena B. Loomis, 324 State Capitol Bldg., Salt Lake City.

Virginia: Richmond, Dec. 4-6. Sec., Dr. K. D. Graves, 30½ Franklin Rd., Roanoke.

Wyoming: *Examination.* Cheyenne, Oct. 6. Sec., Dr. G. M. Anderson, Capitol Bldg., Cheyenne.

---

* Basic Science Certificate required.

BOARDS OF EXAMINERS IN THE BASIC SCIENCES

Arizona: Dec. 16. Sec., Mr. Francis A. Roy, Science Hall, University of Arizona, Tucson.

Arkansas: *Examination.* Little Rock, Oct. 7. Sec., Mr. L. E. Gebauer, 701 Main St., Little Rock.

Colorado: *Examination.* Denver, Dec. 17-18. Sec., Dr. Esther B. Starks, 1459 Ogden St., Denver.

Connecticut: *Examination.* New Haven, Oct. 11. Exec. Asst., State Board of Healing Arts, Mr. W. G. Reynolds, 250 Church St., New Haven 10.

District of Columbia: *Examination.* Washington, Oct. 20-21. Sec., Commission on Licensure, Dr. G. C. Ruhland, 6012 E. Municipal Bldg., Washington.

Florida: *Examination.* Gainesville, Nov. 1. Final date for filing application is Oct. 16. Sec., Dr. W. M. Emmell, University of Florida, Gainesville.

Iowa: Des Moines, Jan. 13, April 13, July 13, Oct. 12. Sec., Dr. Ben H. Peterson, Coe College, Cedar Rapids.

Michigan: *Examination.* Ann Arbor and Detroit, Oct. 10-11. Sec., Miss Eloise LeBeau, 101 N. Walnut St., Lansing.

Minnesota: *Examination.* Minneapolis, Oct. 7-8. Sec., Dr. Raymond N. Bieter, 105 M Hall, University of Minnesota, Minneapolis.

Nebraska: *Examination.* Omaha, Oct. 7-8. Dir., Bureau of Examining Boards, Mr. Oscar F. Humble, State Department of Health, Room 1009, State Capitol Bldg., Lincoln 9.

New Mexico: *Examination.* Santa Fe, Nov. 2. Sec., Miss Marion M. Rhea, 114 E. Marcy, Santa Fe.

Oklahoma: Spring 1948. Sec., Dr. Frank Clinton Gallaher, 813 Braniff Bldg., Oklahoma City.

Oregon: *Examination.* Portland, Dec. 6. Admin., Mr. C. D. Byrne, Univ. of Oregon, Eugene.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Federal Food and Drug Acts: Sufficiency of Evidence to Seize and Condemn Colonic Irrigator.—The United States filed actions for the seizure and condemnation of two devices intended for use as colonic irrigators, bearing plates reading "Tox-Eliminator Company, Inc., Glendale, California" and accompanied by circulars relating thereto. From judgments dismissing the actions, the United States appealed to the Circuit Court of Appeals, Tenth Circuit.

It was stipulated that the sale of the two devices in question had been made, one to a doctor of naturopathy and the other to a doctor of chiropractic; that the devices were displayed, together with certain circulars extolling their merits, in the places of business of these two men for the purpose of selling the services of the devices; that both the devices and the circulars had been transported in interstate commerce. The devices are described as colonic irrigators. They differ from an ordinary enema device in that they have an inflow and an outflow tube. The inflow tube is equipped with a thermostatic valve, by which the temperature of the water can be regulated, and a pressure valve, which limits the pressure of the water entering the body to 40 inches. The outflow tube has a transparent arrangement by which the contents coming from the bowels can be seen and observed as they leave the body. The devices are attached to an ordinary water faucet. One of the circulars involved was labeled "The Modern Scientific Drugless Way to Health," and the other was called "The Magic Power of Water." Much of the controversy centers around the representations contained in these two circulars.

The government's case was based on the testimony of five medical experts, whose qualifications in their respective fields stand admitted. These experts testified that, while they had neither used the device nor seen it in use, they understood fully the principles on which it operated, namely, the washing out of the colon by forcing a stream of pulsating water into the intestines. They explained in considerable detail the physiology of the human system as well as the causes, and treatments therefor, of the diseases listed in the circulars. They admitted, however, that the causes of a number of the diseases listed were still unknown and that the treatments therefor were not definitely catalogued. They testified that intestinal toxemia, referred to in the circular, was not a condition known to medical science and that the function of the colon had little, if anything, to do with the numerous diseases mentioned. In their opinion a colonic irrigation will not cure hardening of the arteries, migraine, lumbago, colitis, gallbladder complications, high or low blood pressure, irregular heart, rheumatism or any of the other named diseases. In conclusion, they said that colonic irrigations are helpful in a limited sense only as relief measures in temporary discomfort caused by severe impaction or as a preparation in case of some major abdominal surgical operations, but that colonic irrigations do not, and cannot, constitute an appropriate treatment for any of the diseases listed in the circulars.

The defense, on the other hand, offered the testimony of Neal Bishop, a chiropractor, and of J. O. Wolvin, the manufacturer and distributor of the devices in question. Bishop testified that the statements in the circulars were true; that he had treated patients with such a device in connection with other therapy, such as chiropractic adjustments and diathermy, and that its use was helpful. He did not, however, testify specifically that its use had effected a cure in a single case of any of the diseases enumerated in the circulars. Wolvin testified that the use of the device had cured him of a chronic case of asthma and said that when the asthma has a tendency to recur, his use of the device eliminates it. The only other evidence offered by the defense consisted of excerpts from several medical books, only one of which stated that a colonic irrigation would aid in the treatment of any of the diseases named in the circular, other than some diseases of the colon.

The excerpts from these medical books were introduced by the defense over the objection of the government. While the authorities are not in complete accord, the weight of authority, said the court, is that medical books and treatises are not admissible to prove the statements therein contained. The trial court, therefore, erred in admitting and receiving in evidence excerpts from these books offered by the defendants for the purpose of establishing the truth of the statements contained therein.

While the trial court did not exclude the testimony of the five medical experts offered by the government, it was of the apparent opinion that their testimony was entitled to no consideration because they had neither tested the device in question nor observed it in operation. That these medical experts were competent and qualified to testify as to the matters in issue, said the appellate court, is clear. They were not disqualified merely because they had neither used the devices in question nor seen them in operation. They testified not only that they were conversant with colonic irrigation but also that they were familiar with the principles of these particular devices. Fundamentally, these devices are not essentially different from any other circulatory apparatus for the purpose of giving an enema. The testimony of these medical experts was competent and constituted substantial evidence.

The trial court found that the two circulars in question constituted labeling as defined in the Food and Drug Act. It did not make a separate finding whether the statements contained therein were true or constituted mislabeling. It must, however, have been of the opinion that it did not constitute mislabeling, otherwise it could not have concluded as a matter of law that the relief prayed for should not be granted. In order for the government to prevail, said the appellate court, it was not necessary to prove that all the representations in the two circulars were false. The charge of mislabeling would be established if the evidence proved any one of the representations to be false. Here the substantial evidence by the government establishes the falsity, with minor exceptions, of practically every one of the broad claims set up in these circulars. The defendants offered positive evidence only as to one claim—asthma. It must therefore be conceded that the government has established the falsity of many of these claims not only by the greater weight of the evidence but by all the evidence in the record.

It may be conceded, the appellate court continued, that the device's use in flushing out the colon under expert supervision has a tendency to eliminate some toxins therefrom, thus preventing their entrance into the blood stream and thus contributing somewhat to the purification of the blood and improvement in general health. But this is not what the labeling circulars state. In effect, they hold the machine out as a cure-all for all the ills that affect the human body. It may be argued that the circulars do not promise a full cure in all these cases but only relief and improvement. A casual reading of the circulars is sufficient to establish beyond doubt that the statements in these circulars would induce and were intended to induce the belief in the minds of many of the ailing and suffering that the "toxeliminator" promised absolute and general relief from all their ailments. The circulars, concluded the appellate court, are inherently dishonest and deceiving and constitute misbranding within the meaning of the Act.

Accordingly the judgments of the trial court denying the government's petition for seizure and condemnation were reversed.—*United States v. One Device, Intended for Use as a Colonic Irrigator, 160 F. (2d) 194 (1947).*

Medical Experts: Training and Experience Required.—The defendants were jointly indicted for murder, found guilty and sentenced to death. From such conviction they appealed to the Supreme Judicial Court of Massachusetts.

The deceased had been shot in the back. The shirt worn by him was found beside the body and there was no bullet hole in it. At the trial the medical examiner, called by the commonwealth, testified that there was in the middle of the back of the deceased a small bullet wound; that "there was very little powder marks outside but there was a ring which could have been made by the muzzle . . . or the jacket of a gun"; that "Beneath the skin was this fairly wide cavity which was blackened and filled pretty much with burnt powder . . ."; that "there was quite a cavity below the skin which was blackened and covered with burnt powder fragments"; that the powder marks on the outside were "just speckles"; that the ring was "interrupted" and about a half inch in diameter; and that there was very little powder on the skin. Thereafter, subject to exception, the witness was allowed to testify that there was at least some powder on the skin about the wound; that the black of the powder was underneath the skin; and that in his opinion the muzzle of "the gun was directly on the skin."

The defendants assign error in that the medical examiner was not sufficiently qualified as an expert to testify that the marks in or about the wound were caused by powder or that the muzzle of the gun was directly on the skin of the deceased. Bearing on qualification, there was evidence that the witness had been a practicing physician, specializing in surgery; that he had been a medical examiner for fifteen years; that he had operated perhaps three times on persons having gun shot wounds, including the type inflicted at close range and the type inflicted at long range; that as medical examiner he had looked at quite a number—about fifteen—bodies where death had been caused by bullet or gun shot wounds, of which about fourteen were bullet wounds; that he believed about eight of these were from bullets fired at close range, all of which, however, were fired through clothing; that he had examined, he should say, six bullet wounds in a nude part of the body, some of these being in the head; but that he had never examined a body where the bullet entered the back of an individual without any clothing.

The defendants argued that the witness was not qualified because it did not appear that he had ever seen a wound from a bullet fired at close range that had not passed through clothing. Assuming that the presence or absence of clothing might affect the appearance of the wound from a bullet fired at close range, said the court, we think it clear, nevertheless, that the professional experience of the witness, particularly with respect to wounds from bullets, both those fired at long range and those fired at short range, would place him in a better position than the average juryman to form conclusions whether the "speckles" observed by him outside the wound and the black appearance under the skin were due to powder and as to the position of the gun when the bullet was fired. A witness's training and experience may well qualify him to give an opinion in reference to a problem which he had never before encountered in precisely the same form. There was no error in allowing the medical examiner to testify as he did.

Other contentions of the defendant were also overruled and the conviction for murder was affirmed.—*Commonwealth v. Bellino, 71 N. E. (2d) 411 (Mass., 1947).*

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1937 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied with stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Leukocyte Counts in Normal White Women Before and After Delivery. L. R. Cason and G. W. Phillips.—p. 483

Hemoglobinuric Nephrosis in Traumatic Shock.—According to Mallory, army experience has made many physicians familiar with the syndrome of renal insufficiency following resuscitation from shock. Lucké has shown that a similar lesion, which he has termed "lower nephron nephrosis," may develop in mismatched blood transfusions, the crush syndrome, blackwater fever, heat stroke, high altitude anoxia, thermal and chemical burns, carbon tetrachloride and mushroom poisoning, and sulfonamide sensitivity. The author has seen it following anaphylactic shock, severe streptococcic infection and infantile gastroenteritis. It is possible to recognize cases in the literature under such titles as interstitial nephritis and hepatorenal syndrome. His discussion is based on 60 fatal cases of battle injury which were studied clinically and pathologically. These observations are reinforced by a survey of 200 similar cases from the files of the Fifteenth Medical General Laboratory. The constant clinical features are oliguria, azotemia, excretion of pigment and albumin in an acid urine and fixation of specific gravity. The appearance of mild hypertension on the third or fourth day is inconstant but is of great diagnostic importance. The initial histologic change appears eighteen to twenty-four hours after injury and consists of lipid vacuolization of the ascending limbs of Henle's loop. The second stage is precipitation of pigment in the distal convoluted and collecting tubules. Moderate dilatation of convoluted tubules follows pigment precipitation. Sometimes on the third day, regularly on the fourth and fifth days, necrosis and regeneration of epithelium in the ascending limbs and distal tubules become evident and simultaneously lymphocytes appear between the tubules and about the vessels. From the fifth day on, rupture of tubules with herniation of their content into the stroma and consequent granuloma formation become frequent. The last development in many cases is the formation of nonocclusive mural thrombi in many of the small veins. In clinicopathologic correlation two factors were constant: the excretion of benzidine positive pigment in the urine and recovery from shock or related physiologic abnormality. Renal insufficiency was found to antedate all structural change but was never progressive in the absence of a demonstrable pigment nephropathy. Although pigment precipitation is an essential factor in the development of the "shock kidney," the mechanism of its effect remains unelucidated.

Agnogenic Myeloid Metaplasia of Spleen.—Levinson and Limarzi point out that Jackson and others in 1940 described a syndrome of extramedullary myeloid metaplasia which they designated as agnogenic. Because this condition is often confused with myelogenous leukemia or acquired hemolytic jaundice, these authors separated agnogenic myeloid metaplasia of the spleen from other conditions. Extramedullary myelopoiesis may occur in various infectious and septic states such as metastatic carcinoma to bone and leukemia. In these types of extramedullary myelopoiesis the clinical and pathologic disorders are known and the therapy and prognosis are obvious. In agnogenic myeloid metaplasia the diagnosis may not always be established, but often one can, by hematologic methods (peripheral, sternal and splenic puncture), clinical examinations and later by microscopic studies of the spleen separate this entity from others simulating it. Levinson and Limarzi tell of a housewife aged 49 in whom agnogenic myeloid metaplasia of the spleen was diagnosed clinically. The essential clinical findings of this condition are insidious onset of progressive weakness, abdominal distress and enlargement of the spleen, with or without hemorrhagic tendency. The hematologic findings are characterized by a slightly elevated leukocyte count with the presence of immature red and white elements in the peripheral blood. A biopsy of bone marrow may show normal, hypoplastic or hyperplastic marrow with myeloid immaturity and no involvement of the myeloblastic tissue. The megakaryocytes are increased and present a normal dispersion. The spleen is enlarged and shows histologically fibrosis and myeloid metaplasia. There was no evidence of myeloid metaplasia in any of the organs other than the spleen.

Kernicterus: Follow-Up on 35 Erythroblastic Infants.—Stiller says that, with the advent of knowledge concerning the pathogenesis and treatment of erythroblastosis fetalis, interest has been focused on the possible untoward effects of a successful therapeutic regimen that may result in a live but helpless infant with kernicterus. The term "kernicterus" was devised by Schmorl in referring to what Orth had called "nuclear jaundice." Among the records in the Children's Hospital in Washington from 1920 up to and including Dec. 31, 1945 there were 47 cases that appear to fit the pattern of erythroblastosis. An attempt was made to have the mother and child in these families typed and to ascertain the child's developmental status. The criteria for inclusion in this series were the typical pattern of an Rh-positive child born of an Rh-negative mother, with the presenting complaint of either neonatal jaundice or anemia. Of 35 for whom follow-up records were obtainable, 29 are still living and 6 have died. The necropsy reports of the 6 deaths failed to show correlation between the degree of clinical involvement of the central nervous system and the pathologic picture. Of the 29 living children 4 show signs of involvement of the central nervous system that may be interpreted as evidence of kernicterus. Two of these 4 showed evidence of involvement of the central nervous system in the neonatal period. None of the remaining 25 normal children showed such neonatal involvement. Transfusion therapy should be directed against the anemia and is of no value in ameliorating the damage to the brain that has already occurred.

Familial Hypoplastic Anemia of Childhood: 8 Cases in Two Families.—Estren and Dameshek present two families with familial hypoplastic anemia. Three of 7 siblings in the first family and 5 of 14 siblings in the second family had apparently identical disorders characterized by peripheral pancytopenia, pallor, weakness and a bleeding tendency. Hypoplasia of the marrow was present in those cases in which the marrow was examined. These are the first recorded instances in which hypoplasia of the marrow has been noted as the sole familial trait. The closest similar cases in the literature are those of Fanconi, in which hypoplasia of the marrow was one of several congenital and familial abnormalities. Familial hypoplastic anemia must be added to the other heredofamilial hematologic conditions. Splenectomy in 1 of the patients resulted in pronounced improvement. In cases of complete or almost complete aplasia of the marrow and in cases in which a reduction of blood platelets is accompanied by a reduction or absence of megakaryocytes in the marrow, splenectomy would not be of value. Splenectomy may be considered as offering a beneficial therapeutic result when megakaryocytes are present to some degree in the marrow, and particularly when lack of platelet production in the megakaryocytes can be demonstrated and the red cell elements show some evidence of regenerative activity.

Orientation to Forensic Psychiatry. H. A. Davidson.—p. 730.

Loss of Axis Cylinders in Sclerotic Plaques.—Putnam and Alexander call attention to the fact that different stains lead to contradictory observations on the damage to axis cylinders in sclerotic plaques. The ideal method of resolving the difficulty would be to find a stain which combines the best features of the technics which are found to give conflicting results. Such a method has recently become available: the Bodian stain, which depends on the reduction of a silver proteinate. Twenty-six blocks containing 31 distinct plaques were taken from embedded material from 7 cases of multiple sclerosis. Studies by means of the Bodian silver stain for axis cylinders showed that some degree of damage or destruction of axons occurred in all the sclerotic plaques investigated. In all but 2 of the plaques examined the axis cylinders were reduced to a small fraction of the normal number. The pathologic appearance of surviving axis cylinders was more striking in fresh plaques than in old ones. Similar changes of about the same degree of intensity were seen in some other lesions of vascular origin not sufficiently intense to cause complete necrosis. The evidence here presented is compatible with the point of view that the parenchymal lesions in multiple sclerosis are secondary to a local disturbance of circulation. It suggests that the conception of a specific process of demyelination peculiar to multiple sclerosis deserves revision. The fact that fibrous gliosis is not observed in the most acute lesions of multiple sclerosis suggests that the glial scar is secondary to the local destructive process. The fact that many axis cylinders are damaged in lesions of multiple sclerosis has also an important bearing on prognosis and treatment. The acute stage of swelling and distortion of axis cylinders seems to correspond to the acute stage often observed in symptoms. There seems to be little hope that treatment would increase the number of existing axis cylinders once the lesion is formed.

Electroencephalographic Studies Following Electric Shock.—In the 51 patients studied by Weil and Brinegar varying numbers of electric shock treatments were administered by a machine delivering unidirectional fluctuating current. Brain waves were recorded prior to treatment, four days after the last treatment and fourteen days thereafter. The highest percentage of abnormal records was obtained in manic-depressive patients, closely followed by that for the schizophrenic group. Patients with involutional psychoses and psychoneuroses demonstrated more normal preshock records. In general, an increase of abnormality in the electroencephalographic record was observed after treatment, but the electroencephalograms of a large percentage of patients receiving less than ten shock treatments had returned to normal fourteen days after the last treatment. The electroencephalographic changes seemed to be less pronounced after shock treatment when unidirectional current was used than when alternating current was used. Postshock electroencephalograms closely resembled the records of epileptic patients. The following clinical relationships between various changes in the brain waves and the psychiatric picture were found: (*a*) An abnormal preshock electroencephalogram usually indicated that a longer course of treatment was necessary in order to achieve clinical improvement. (*b*) A highly abnormal electroencephalographic record fourteen days after the last treatment was usually found with patients requiring further hospitalization. (*c*) A normal preshock electroencephalogram promised a better clinical result from electric shock treatment than an abnormal preshock record.

Experience with Salmonella Typing in Canada. L. E. Ranta and C. E. Dolman.—p. 286.

Diphtheria Toxoid and Pertussis Vaccine.—Greenberg and Fleming found evidence in experiments on guinea pigs that the addition of pertussis vaccine to diphtheria toxoid enhances the immunizing power of the latter. Quantitative determinations demonstrated that as the numbers of pertussis organisms are increased the immunizing efficiency of the diphtheria toxoid also is increased. The concentrations of pertussis organisms usually found in commercial preparations increased the immunizing efficiency of the toxoid at least twofold.

Retention of Ascorbic Acid in Canned Fruit Juices During Storage After Opening.—Branion and Cameron found that the loss of ascorbic acid from fortified apple juice is greater than from tomato juice, tomatoes or grapefruit juice during storage in open containers either at room temperature or in a refrigerator. Loss of ascorbic acid from tomato juice, tomatoes and grapefruit juice under the same conditions was negligible for twenty-four hours' storage and was small up to forty-eight hours, particularly during storage in the refrigerator.

Backache and Fibrositis.—According to Caven, fibrositis is the name given to a condition that produces in certain susceptible individuals small nodules in the connective tissue; these are sometimes painful or may give rise to referred pain or may be only tender to the touch. It is probably the most common cause of pain in the large group of individuals who suffer from so-called rheumatic conditions. Some authors speak of fibrositic nodules and others, mostly English, of rheumatic nodules. In the English literature fibrositis is usually grouped with rheumatic conditions, in which are also included various types of arthritis. The author thinks that fibrositis should be kept separate from these conditions, as there is no evidence of infection. The predisposing causes have been listed as sudden strain, wear and tear, chill, worry, poor posture and lack of use of certain groups of muscles. The essential pathology of fibrositis is now well known, as Stockman has described the changes in the white fibrous tissue of the muscles, nerves and fascia as being due to edema with serofibrinous exudation; in this the fibroblasts proliferate rapidly, numerous minute new blood vessels appear and the whole forms a soft, ill defined, congested little swelling. The author regards fibrositis as one of the most common causes of backache and of pains referred to the back. Along with fibrositis there usually exists some muscle spasm. Physical therapy is most important in the treatment. In the acute case with sudden onset, heat and rest with the use of analgesic drugs may be necessary for the first few days before massage can be used. In the more chronic cases manipulation and deep massage can be used from the start. The essential part of treatment is to stretch the tissues involved, by some means or other, either by traction when that is possible or by firm massage directly on the tender nodules. Before any manipulative treatment is undertaken it is wise to have x-ray films made of the spine to rule out abnormal bone conditions. The author describes manipulations to be carried out by the physician and exercises to be done by the patient.

March Hemoglobinuria.—Bell defines march hemoglobinuria as the condition in which free hemoglobin appears in the urine during and after erect exercise, such as running and marching. This hemoglobinuria is preceded by an elevation above normal of the free hemoglobin in the blood. A youth aged 18, who exhibited the syndrome of march hemoglobinuria for almost three months, was under observation during the last two. The history, negative Wassermann reaction and inability to produce a paroxysm when exposed to chilling, as well as the remission, ruled out any other type of paroxysmal hemoglobinuria. The presence of food in the upper digestive tract as long as three hours after its ingestion was a factor in the development of the paroxysms. When the upper digestive tract was empty, that is, seven or more hours after a meal, erect exercise did not precipitate symptoms. Erect exercise caused the appearance or the increase of albuminuria at all times. No theory can be formulated to explain why an apparently normal young man should suddenly exhibit for three months hemoglobinemia, hemoglobinuria, albuminuria and abdominal distress after walking for thirty minutes. Nor can any explanation account for the fact that for at least part of the three months the appearance of these symptoms depended on the presence of food in the upper digestive tract.

Serologic Studies on Influenza.—Studies described by Kalter and Chapman were designed to ascertain the approximate time of the appearance of epidemics or an indication of their approach by preepidemic increases in serum antibodies, to determine the nature of the epidemic in this area, to determine the effect of vaccination and to determine what antibody titers may be expected in presumably normal persons. The epidemic in the area studied was due to influenza B. This virus was present for several months before the actual outbreak. Recognition of the preepidemic period makes it possible to employ the vaccines early enough. Vaccination results in an antibody increase lasting in most cases for at least five months. Vaccines should then be administered in the fall of the year in order to prevent infection. Serologic studies are of value in (*a*) determining the etiologic agent, (*b*) ascertaining the duration of antibody titers and (*c*) estimating the approximate time for administration of vaccines. These tests may be used by the laboratory to ascertain the etiology of this type of respiratory infection.

Comparative Action of Mecholyl Chloride and Histamine.—The reaction of the tracheobronchial tree, measured chiefly by changes in the vital capacity, to mecholyl chloride administered intramuscularly in doses of 0.25 to 6.0 mg. was determined by Curry in 10 normal subjects, 11 patients with uncomplicated hay fever and 27 patients with active bronchial asthma or a history of asthmatic attacks. In the latter two groups the reaction was compared with that due to parenteral histamine administered chiefly by the intravenous route in doses of 0.02 to 0.04 mg. of the base. In the normal group 3 subjects had a slight reduction in vital capacity after the intramuscular injection of 6 mg. of mecholyl chloride, though all noted a feeling of tightness in the chest. All the patients with hay fever had a slight reduction in vital capacity following the administration of 6 mg. of mecholyl chloride intramuscularly, and in 7 cases the reduction was 5 per cent or greater. By contrast, in the latter group the intravenous administration of 0.02 to 0.03 mg. of histamine base caused a reduction in vital capacity in 6 of 11 subjects, but in only 2 cases was the decrease 5 per cent or greater. In the 27 subjects with bronchial asthma all had a reduction in vital capacity after the intramuscular injection of from 1 to 6 mg. of mecholyl and in only 1 instance was the decrease less than 5 per. cent. On the other hand, following the administration of parenteral histamine, 23 subjects had a reduction in vital capacity, and in 22 of these cases the reduction was 5 per cent or greater. It appeared that patients with hay fever and asthmatic subjects were more reactive to mecholyl chloride than to histamine and that both drugs acted by different mechanisms on the hyperresponsive respiratory tract of these persons.

Thiourea Plus Iodine in Hyperthyroidism.—According to Winkler and his associates the thyroid depressant effect is enhanced if thiourea is used in combination with strong solution of iodine. He cites facts which suggest that the dosage initially employed was unnecessarily large. The present study arose from an attempt to avoid hypothyroidism by the use of the minimimum effective dose of thiourea. Effects of small doses of thiourea, 0.075 to 0.015 Gm. daily, together with iodine solution in inducing and maintaining a remission in hyperthyroidism were studied. Doses of thiourea as small as 0.07 Gm. daily, in conjunction with iodine solution, produced a remission in hyperthyroidism with considerable regularity. The remission in hyperthyroidism can usually be maintained by the use of 0.05 to 0.025 Gm. of thiourea daily in addition to iodine solution. Withdrawal of thiourea, even when the maintenance dose is as low as 0.025 Gm., is frequently followed by exacerbation of previously controlled hyperthroidism. Control of hyperthyroidism with iodine solution alone is only rarely possible, with or without previous thiourea treatment. Prolonged, and perhaps indefinite, maintenance on thiourea and iodine is necessary to prevent recrudescence of hyperthyroidism.

Lung Calcification and Histoplasmin Tuberculin Skin Sensitivity.—Sontag and Allen report investigations of serial chest x-ray and histoplasmin-tuberculin sensitivity reactions in 170 essentially "normal" southwestern Ohio children. They applied haplosporangin and blastomycin skin tests to thirty-three children with positive calcification and negative skin reactions. They reemphasize the findings of other investigators that a far greater number of children are sensitive to histoplasmin than to tuberculin and that the incidence of pulmonary calcification is much more closely associated with the incidence of histoplasmin sensitivity than with tuberculin sensitivity. There is a much closer association between the onset of the calcification and the development of histoplasmin sensitivity than between calcification and the development of tuberculin sensitivity. A considerable number of calcifications occur in children negative to both histoplasmin and tuberculin. One of these was associated with a positive blastomycin test and one with positive haplosporangin plus a positive blastomycin test. In this series there is a tendency for familial distribution of positive lung calcifications, but not of positive histoplasmin skin reactions. The majority of the calcifications in this study have their soft tissue changes before 48 months of age. Many of these can be traced back to the early months of life. Infiltrates and occasional round areas of consolidation are the precursors of the calcifications in the parenchyma. Progressively appearing new lesions followed by new calcifications both in parenchyma and in hilus are often seen in histoplasmin positive children over a period of several years.

Sexual Precocity and Accelerated Growth of Child with Follicular Cyst.—Kimmel observed a girl aged 25 months in whom the presenting complaint was vaginal bleeding. There was hypertrophy of the breasts and nipples, with quite prominent pigmentation about the nipples. The labia minora were moderately enlarged. Combined rectoabdominal examination revealed a moderately enlarged uterus. The child was very tall for her age, her height being 39½ inches (94 cm.), 5 inches (12.7 cm.) taller than the average. A tentative diagnosis of granulosa cell tumor of the ovary was made. At operation the right ovary was found to consist chiefly of a cyst 4 by 3 cm. in diameter, which had destroyed most of the ovarian tissue. A right salpingo-oophorectomy was performed. There was no evidence of a granulosa cell tumor, but it was assumed that sufficient estrogen to cause the changes noted might have been produced by granulosa cells which lined the cyst. It has now been four years and four months since the cyst was removed. The patient has been seen several times during this period. There has been no recurrence of vaginal bleeding, and the labia, uterus and breasts have regressed to normal size. A search of the literature revealed only 2 previously reported cases similar in some respects to the case reported here.

Biologic Assay of Human Kidney Tumors by Heterologous Ocular Transplantation.—This investigation by Masina is an attempt at biologic assay of some of the tumors of the human kidney encountered by the urologist. Studies were made on 1 papilliferous epithelioma of the renal pelvis from a man aged 37, 1 clear cell carcinoma from a woman aged 61, and 1 granular cell carcinoma from a man aged 60. The specimens for transplantation were obtained in the operating room, were transported to the laboratory under sterile precautions and immediately transplanted into the anterior chamber of the eyes of a series of male and female guinea pigs. These three different types of tumors display in heterologous ocular transplantation activities of their cells which may greatly modify previous concepts concerning the evaluation of the degree of malignancy solely in terms of morphology of the tumor cells. It was disclosed that the relatively benign papilliferous epithelioma can be heterologously maintained, whereas the highly malignant granular type gave negative results, a feature which was unexpected. The cytologic evidence of transition of clear cell type toward granular cell variety suggests that the clear cell carcinoma may be a precursor of the granular cell, and the formation of granules in the clear cells may possess some endocrine function that may initiate in the patient a chain of interrelated biologic phenomena responsible for the clinicopathologic manifestations displayed by the granular cell carcinoma of the kidney in the human subject, a sequence which is not initiated in the guinea pig. The absence of this sequence may be responsible for negative results with the transplantation of the granular cell carcinoma, as also for the absence of metastases throughout the series.

Solution of Vesical Calculi.—Abramson reports that the bladder calculi of 7 patients detected among 35 paraplegic patients responded by disintegration to irrigations with solution G. The time necessary to dissolve the bladder calculi ranged from six to forty-four days, the average being fourteen days. The method of treatment is outlined.

Streptomycin in Treatment of Tuberculosis of Urinary Bladder.—Redewill reports that 2 patients with tuberculosis of the urinary bladder responded to treatment with streptomycin. The development of bacterial resistance to streptomycin can be avoided by administering parenterally no less than 800,000 units of the drug in eight doses three hours apart each twenty-four hours. It was also found that streptomycin will check the tendency of tubercle bacilli developing increased resistance if penicillin is administered along with streptomycin. Penicillin alone has no demonstrable effect on tubercle bacilli, but when given with streptomycin, it enhances the bacteriostatic effect. The first of the 2 patients was started on 100,000 units of penicillin in beeswax and peanut oil daily by injection and sulfathiazole by mouth. Streptomycin was administered both parenterally (800,000 units daily) and by bladder iontophoresis twice a week. After six weeks of treatment the bladder was normal and the patient was declared apparently cured. The follow-up disclosed no recurrence of bladder symptoms. In the second patient cystitis and ulceration cleared in eight weeks. This patient also had incipient tuberculosis of the right kidney and involvement of the left seminal vesicle and epididymis, all of which apparently cleared under streptomycin treatment. Treatment with quartz light is an important adjunct. Redewill describes a modification of the Caulk intravesical application of ultraviolet light.

Products of Plasma Fractionation.—Janeway shows that separation of blood into its functional components makes it possible to accomplish many therapeutic purposes. For instance, if the plasma from 8 pints is fractionated, there is obtained two 25 Gm. bottles of albumin, several packages of blood grouping globulins, twelve 5 cc. vials of gamma globulin, several packages of fibrin foam and film, an excess of thrombin and ultimately, it is hoped, a number of other useful products. In addition, important tools have been secured for the study of disease. It has been possible to do things which could not be done with whole blood. By giving albumin it is possible to raise the patient's serum albumin level and by that means we have learned a lot about the control of water balance in liver disease and we are learning something about nephrosis, in which albumin is probably not the answer to the problem. The problem arises as to how these agents are to be secured. They were developed for the army and navy but not for civilian use, although certain surplus products, dried plasma and gamma globulin are being distributed by the Red Cross. In Massachusetts and Michigan the Red Cross is cooperating in getting donors. Blood is collected by the states and is processed in the states' own laboratories. It is planned to distribute whole blood, resuspended red cells, plasma, albumin, gamma globulin and the whole range of blood derivatives at public expense. It is to be hoped that programs will be developed in different parts of the country, each best suited to the facilities and needs of the area.

Androgenic Arrest of Familial Enuresis.—Kugelmass studied 75 children with familial enuresis with and without emotional and training difficulties because they failed on all forms of therapy. Boys predominated in this group (3 to 1) probably because of their greater difficulty in learning bladder control. Treatment consisted in the administration of methyl testosterone 10 to 30 mg. daily in divided doses for one to three months. If oral administration produced no significant improvement within a fortnight, it was supplemented with intramuscular administration weekly of 10 mg. of testosterone propionate. Fluid intake was restricted except for milk morning and noon, cracked ice between meals, and rinsing of the mouth with water to quench thirst. Mothers were advised to remain unemotional about wetting episodes, because parental anxiety has an untoward influence on the child's psyche. Fifty-nine children were cured, 10 were improved and 6 failed to benefit from this treatment.

Ocular Findings in Diabetic Children.—In routine fundoscopy of 128 diabetic children, Givner and Lodyjensky found 3 who had retinal hemorrhages and 1 a diabetic cataract. Since none of the patients had complaints referable to vision, and since the importance of retinal hemorrhages in regard to a better evaluation of the case has been emphasized, it would seem good practice to study every diabetic patient under a mydriatic. Special emphasis should be put on pinpoint hemorrhages and aneurysmal capillary dilatations, as they can be overlooked easily.

Early Ambulation After Cataract Operation.—Smith says that although the early ambulation of postoperative cataract patients is a departure from the conventional, this procedure was carried out on a series of 60 nonselected patients during 1946 with results comparable to those obtained with prolonged bed rest and quiet. In all these cases a monocular dressing was applied immediately after surgery, and the patients were allowed out of bed in from sixteen to twenty hours later. The nursing problem was practically nil. The patients for the most part looked after themselves, and because of the monocular dressing the hysterical problem sometimes seen was not encountered. The fact that no iris prolapses ensued and that the anterior chamber quickly reformed, and for the most part stayed reformed, may be attributed to the high conjunctional flap and the excellent coaptation of the limbal wound obtained by the Daily scleral conjunctival technic.

Intestinal Extract in Rheumatic Diseases. — Renshaw found in postmortem examinations that atrophy of the small intestine was often severe in patients with rheumatic disorders. He decided to test the effect of extract of intestinal mucosa. Enzyme specialists agreed to prepare an extract of intestinal mucosa rich in erepsin. The resulting product was presented in enteric coated capsules for oral administration. These were designed to release their contents one hour after being swallowed. Since the hydrochloric acid of the gastric juice would inactivate the enzymes, an interval of two and a half hours after food seemed to be the optimal time for administration; this would allow the intact capsule to pass into the duodenum, there to dissolve and liberate its contents for subsequent action in an alkaline medium. Treatment of patients with this extract have now been proceeding for seven years. Most types of rheumatic disease have been treated—rheumatoid arthritis, osteoarthritis, fibrositis, synovitis, intermittent hydrarthrosis, acute and subacute rheumatism and spondylitis. Among over 700 cases treated by the writer personally, good results have been obtained in rheumatoid arthritis, osteoarthritis and fibrositis. Also some intractable cases of ankylosing spondylitis and Still's disease have responded to this therapy. The beneficial effects observed as a result of the administration of the intestinal extract in various rheumatic conditions would appear to indicate a common factor underlying all and to support the idea of a rheumatic diathesis. This rheumatic diathesis may be a constitutional state of the tissues, inherited or acquired, as a result of which such tissues are more vulnerable to the action of toxins, bacterial invasion or trauma, and the ill effects of which are further aggravated by defects in intestinal digestion and assimilation.

Severe Erythema Multiforme. I. B. Sneddon.—p. 925.

New Euphoriant for Depressive Mental States.—Stockings believes that the syndrome of thalamic dysfunction, or neurotic depression, is frequently encountered in general practice and is often one of the most intractable. The commonest forms of the condition are the chronic neurotic depressions, anxiety states, reactive and hysterical depressions, and obsessional disorders. The depressions of later life, in which the dysphoria is unaccompanied by hallucinosis, delusions and other gross psychotic symptoms may also be included in this group. The essential feature of these disorders is that the perception threshold for unpleasant affects and sensory impressions is lowered, while that for pleasant sensation is correspondingly raised—the anhedonic or dysphoric syndrome. Although it is generally believed that these conditions are psychogenic in origin, there is evidence that the basis of the condition is primarily a disturbance of the thalamic-hypothalamic mechanisms, possibly a metabolic disorder. During the last century attempts were made to utilize the euphorigenic properties of cannabis in the treatment of depressive states, but these were found to be unsatisfactory. The discovery of the new synthetic cannabis-like derivatives of the dibenzopyran class has given new types of euphoriant drugs. One of the most active pharmacologically is the synthetic hexyl analogue called synhexyl, pyrahexyl or parahexyl. The drug was given to 50 patients showing the thalamic dysfunction syndrome. The dosage employed varied from 15 to 90 mg., the drug being administered on rising in the morning. Thirty-six showed improvement, while 14 were unaffected or made worse. Of the 6 illustrative cases, 4 were dysoxic (psychotic-depressive) and 2 were examples of simple thalamic dysfunction (neurotic depression).

Nitrogen Mustards in Hodgkin's Disease.—ApThomas and Cullumbine say that the effects produced by nitrogen mustards in animals are similar to those caused by x-rays and that for this reason it was assumed that they might prove useful in the treatment of malignant disease. Reports by American authors induced them to try nitrogen mustards in treating 25 patients, 21 of whom had Hodgkin's disease in an advanced stage, some recurrent after radiotherapy, and 4 had other reticuloses. The diagnosis in all cases was confirmed by biopsy. On the basis of the results obtained the authors conclude that the nitrogen mustards are useful in the palliative treatment of extensive Hodgkin's disease, the manifestations of which are consistently diminished. The symptoms can still be alleviated by nitrogen mustard in cases in which radiotherapy has been abandoned. Leukopenia seems to be the limiting factor as far as dosage is concerned. The tris form of the drug has shown no better results than has the bis compound. Diminution of leukocytes and of platelets is more severe after the tris form. Radiotherapy is to be preferred as a first treatment in Hodgkin's disease; for, though the improvement with x-rays is slower, it is maintained longer and the side effects are less serious.

*Tuberculosis Infection in Nurses. D. Anderson.—p. 752.
Victoria's Tuberculosis Problem. H. M. James.—p. 754.

Incidence of Tuberculosis in Male Medical Students.—Lowe and Hallam report a survey to determine the incidence of skin sensitivity to tuberculin and the incidence of active pulmonary tuberculosis in medical students. No difference in the proportion of positive skin reactors is found between medical students in the preclinical years and the general university population of the same age. A significant increase in the proportion of positive skin reactors is seen in medical students at the end of their clinical years. No case of active pulmonary tuberculosis was found among medical students in their preclinical years, but an incidence at least four times as high as that in the general population occurred among these students during their clinical years.

Tuberculosis in Nurses.—Anderson applied the intracutaneous tuberculin test to nurses at eleven hospitals of the New South Wales. He was able to report the reactions in 2,705 nurses. Tables and graphs indicate that the rate of infection is greater in nurses than in other young women. It may be inferred that the nursing of tuberculous patients in the general hospital in special wards pays good dividends in the protection of nurses from infection. Removal of tuberculous patients from the general wards was followed by a lessening of the frequency with which nurses became infected during their training.

Causes of Hemoptysis.—Aanonsen reports that in 112 out of 275 patients from Ullevål Hospital admitted on the diagnosis of hemoptysis the cause was pulmonary tuberculosis; 88 had active tuberculosis, and in 33 of these the hemoptysis had led the patient to seek medical attention. Among the 153 patients without evidence of tuberculosis there was pulmonary tumor in 4, certain bronchiectasis in 40 and probable bronchiectasis in 27, bronchitis circumscripta nonspecifica (Leegaard) in 9, pulmonary infarct in 12 and bleeding from the throat in 12. In 22 no certain cause of the hemoptysis could be found

Eczema in Infants from Pediatric and Dermatologic Points of View.—Wallgren states that eczema in infants is an expression of a constitutional anomaly on a hereditary basis. The eczema usually appears at about 3 months and disappears before the age of 2 or 3. The cause of the manifestation as well as exacerbation is often acute infection or mechanical, thermal or chemical irritation of the skin. Hypersensitivity to certain foods does not as a rule seem to be significant, and diet plays a subordinate role in treatment; only in exceptional cases does elimination of certain aliments lead to definite improvement. Of greater value are partly the elimination of acute infections and cutaneous irritations of various kinds and partly local dermatologic treatment.

*Clinical Picture of Retrobulbar Neuritis in Intracranial Tumors. S. Larssen and B. Nord.—p. 1059.

Significance of "Histamine Antagonists" in Treatment of Allergic Disease.—Kallós concludes that antasten (2-phenyl-benzyl-aminomethyl-imidazolin), a histamine antagonist not employed in the United States, is valuable in the symptomatic treatment of urticaria, angioneurotic edema, neurodermatitis, serum sickness or exanthem due to drugs, Ménière's disease and certain forms of headache, but without effect in the treatment of migraine or asthma. The general reactions which occasionally appear on specific desensitization can probably to some extent be influenced by antasten. Its toxicity is slight and it may be given orally, injected intramuscularly or intravenously and be applied directly to the mucous membrane (eyes, nose). There is no indication that histamine antagonists affect the antigen-antibody reaction and the cell injury it causes.

Effect of 2-Phenyl-Benzyl-Aminomethyl-Imidazolin in Allergic Disease.—Use of this preparation in the treatment of 43 outpatients with vasomotor rhinitis, angioneurotic edema, urticaria and asthma, Skouby says, gave good results in the first three groups and was without effect in the fourth group. By-effects, seen in 13 patients, persisted in only 7 on the necessary maintenance dose. In 2 instances treatment was discontinued because the discomforts from it were more annoying than the symptoms. The majority of patients with urticaria were women and in several cases the symptoms were aggravated in connection with the menses, which suggests that the disorder may have an endocrine basis.

Clinical Picture of Retrobulbar Neuritis in Intracranial Tumors.—Larssen and Nord warn that in cases of tumor in the anterior and middle fossa reduced vision and central scotoma with or without papilledema or atrophy of the optic nerve constitute an early symptom the diagnostic value of which is frequently not recognized. The symptom is often attributed to sclerosis disseminata, and surgical intervention is thus delayed. Especially in cases with a protracted course, encephalography is indicated. Eight personal cases, namely 2 of meningioma of the olfactory groove, 2 of suprasellar meningioma, 1 case of meningioma originating in the lesser wing of the sphenoid, 1 of adenoma of the hypophysis, 1 of hypophysial duct tumor and 1 of subfrontal meningioma, are described in detail. All presented diagnostic difficulties, and retrobulbar neuritis was prominent in all. Spontaneous improvement in vision suggested the erroneous diagnosis of sclerosis disseminata in the first 4 cases, 1 case was ascribed to anemia, 1 possibly to brain trauma, 1 to arteriosclerosis; in only 1 case was cerebral tumor diagnosed without preceding misconception.

*Experimental Research on Leukemias and on Tumors of Reticuloendothelial System. M. Guérin.—p. 13.
Hemopathy as Untoward Reaction. A. Tzanck and B. Dreyfus.—p. 37.

Leukemias and Tumors of Reticuloendothelial System.—Guérin's experiments on chickens, rats and mice at the Cancer Institute of the University of Paris revealed an intimate relationship between leukemia and tumor growth. This was demonstrated by the production of sarcoma in chickens by inoculation with various leukemic strains. A myeloma was produced in rats at the point of entrance of an injection of crushed liver and spleen from a rat with chloroleukemia. The cycle was completed by the appearance of a myeloid leukemia in the advanced stage of the tumor. The only difference between the leukemias or the tumors of the birds and of the mammals consists in the fact that in the first the determining agent may be isolated from the cell in virus form, while in the second it is intimately connected with the leukemic or neoplasmic cell and cannot be separated from it by filtration. Immune phenomena were demonstrated concerning the leukemia in chickens which suggest the use of serum therapy or vaccination as effective means of combating the disease. Definite recovery resulted in 7 of 10 chickens with virulent leukemia from intravenous injections of massive doses of 6 methoxy-8 diethylamino-n-propylamino-quinoline (rhodoquine). Crushed liver injections from mice with spontaneous reticuloendotheliosis were given to mice; a diffuse reticuloendotheliosis was produced in some of the animals, a pseudoleukemic granulomatosis in others and subcutaneous sarcomas in several animals. Two of these sarcomas were successfully [illegible] Leukemias or tumors of the [illegible] duced in chickens by painting [illegible]

Book Notices

Practical Anæsthetics for Students, Hospital Residents and Practitioners. By J. Ross Mackenzie, M.D., D.A., Senior Anæsthetist, Royal Infirmary, Aberdeen. With foreword by W. C. Wilson, M.B., Ch.B., F.R.C.S.E. Second edition. Fabrikoid. Price, $3. Pp. 172, with 71 illustrations. William Wood & Co., Mt. Royal & Guilford Aves., Baltimore 2, 1946.

The popularity of Mackenzie's book is indicated by the demand for a new edition less than two years after the printing of the first. The author has fulfilled a double object: to provide students, hospital residents and general practitioners with a guide to the administration of the most commonly used anesthetics, also to give a summary of the knowledge of anesthetics which every student should possess on graduation.

He describes the preparation and after-care of the patient and gives directions for administration of the commonly used anesthetics: ether, chloroform, ethyl chloride, intravenous pentothal and nitrous oxide with oxygen. He describes the necessary apparatus and the technic of administration of the gas anesthetic agents. He has chapters on endotracheal, on intravenous and on local and regional anesthesia, including the spinal and splanchnic technic, on anesthesia and analgesia in obstetrics, on the choice of the anesthetic agent, on complications and sequelae of anesthesia, and on anesthesia for some special operations.

Anesthetic practice in Scotland differs in some respects from ours. We find that susceptibility to anesthetic drugs varies with the metabolic rate rather than with the weight of the patient. We agree that the stomach should not contain solid food and that liquids may be taken up to a few hours before operation, but we find that a simple enema given on the evening before operation reduces the chance for postoperative nausea and vomiting. The author's list of thirty-three items of essential anesthetic equipment may be confusing to the beginner or the occasional anesthetist. We do not think that trichlorethylene has had sufficient trial to warrant its recommendation to the beginner.

The book has chapters on oxygen therapy, on medicolegal notes and on anesthetics today and tomorrow. It provides interesting reading, well illustrated.

Morell Mackenzie: The Story of a Victorian Tragedy. By R. Scott Stevenson. Cloth. Price, $5. Pp. 194, with illustrations. Henry Schuman, 20 E 70th St., New York 21, 1947.

This story of more than half a century ago has needed retelling. Beside the figure of Mackenzie, a leading otolaryngologist of his day, pass those of Germany's last kaiser, Emperor William II and his ill fated father; of Virchow, von Bergmann, Queen Victoria and her household, Bismarck and others.

The author is a laryngologist of standing in London. His former chief, Mr. Irwin Moore, had known Mackenzie and felt that he had been misunderstood and poorly treated. The author takes us to a remotely familiar time of leisurely and spacious living in an England proudly confirmed in her world leadership.

Morell Mackenzie's polished and cultured father was a general practitioner in a village 6 miles from London. The son was ambitious and his medical education was excellent. He attended the magnificent clinics on the continent and met Charcot, Nélaton, Trousseau, Bretanneau, Rokitansky, Skoda and Czermak, who had popularized the laryngeal mirror and so helped to establish modern laryngology. Mackenzie had great ability. In 1887 he was called in consultation to see Crown Prince Frederick of Germany. The prince had been seen only by German physicians; they had diagnosed carcinoma of the larynx and advised operation.

Mackenzie examined the crown prince and opposed operation until a biopsy could be made. The first and subsequent ones were pronounced negative for cancer by Virchow. Operation was postponed but later it became necessary to do a tracheotomy. The patient's father, the emperor, died in a few weeks. The crown prince ascended the throne to rule for about three months and then passed away, to be succeeded by his son, Kaiser William II, the last emperor of Germany.

There have been few medical cases about which there has been more debate, mystery, recrimination and hidden politics. Some said that Mackenzie was influenzed by British statesmen not to pronounce the crown prince a victim of incurable disease. It was in British interests that the prince succeed his father and make his wife, who was a British princess and the daughter of Queen Victoria, an empress. It is hard to believe that Mackenzie would lend himself to this sort of thing. Mackenzie, by present day standards, was correct in insisting on a biopsy. Virchow's negative report led to the delay which later made laryngectomy the only possible treatment. This operation in those days had a high mortality, and the patient refused to consider it. As for Mackenzie, possibly the best explanation of circumstances which led to his unhappiness was that the prince had a carcinoma low in the larynx, the so-called subglottic type, from which it was not possible to obtain a proper specimen. This was before the anesthetic properties of cocaine had been discovered and before laryngologists had our modern electrically lighted instruments.

This biography can be read with profit by any one interested in the politics and intrigues of a day not so long past.

Le problème biologique du cancer. Par Jacques Delarue, professeur agrégé à la Faculté de médecine de Paris, Paris. Préface de M. le recteur G. Roussy Paper. Price, 300 francs. Pp. 200, with 31 illustrations. Masson & Cie, 120 Boulevard Saint-Germain, Paris 6^e, 1947.

The first 140 pages of this monograph contain a summary of present knowledge of cancer from the clinical, experimental and public health points of view. This section mentions and discusses most of the important facts concerning cancer that have come out in the last few years, such as the work with carcinogens, hormones, heredity, the milk factor and transplantation into the eye. The author does not fully realize the advances in surgical technic that have been particularly striking in the United States in the last few years and his judgment as to the treatment is hampered by such ideas as "pneumonectomy and lobectomy are very dangerous operations."

The last 60 pages consist of a discussion of the causes of cancer, the causes of recurrence and the causes of metastases. This discussion starts with the theory that cancer arises as a result of chemical changes in the body as a whole and in the local area in particular. He believes strongly that when cancer arises at one point in a tissue it is also likely to arise at other points in the same tissue. This agrees fully with the studies of Shields Warren in this country, but the author apparently does not know of his work. He is on a sound basis in discussing recurrences in the local operative area. These, he believes, are due either to gross tissue left behind at an incomplete operation or to the development of a new cancer which we in the United States have been distinguished for some years as re-occurrence. His discussion of metastasis, however, is not so sound. He believes that metastases are not due to the transplantation of cancer cells to other parts of the body but to an influence either chemical, viral or neurogenic which causes a metaplasia of the cells in the neighborhood in which this influence works, the result of which is a local area of cancer identical or nearly identical in structure with the primary focus of cancer. Such theoretical material will undoubtedly leave many serious students of cancer cold.

The value of the book to students of cancer is reduced by its complete absence of a bibliography. The author quotes many authors by name in the text but does not mention the date of the particular work that he is quoting.

The Acute Infectious Fevers: An Introduction for Students and Practitioners. By Alexander Joe, D.S.C., M.D., F.R.C.P., Medical Superintendent, City Hospital, Edinburgh. Fabrikoid. Price, $4.50. Pp. 276, with 64 illustrations. Blakiston Co., 1012 Walnut St., Philadelphia 5, [n. d.]

In the preface it is stated that, "whilst it would be too much to expect that those with great experience of the subject would agree with all the views expressed, the latter at least ought to form a reasonable guide for the beginner until adequate observation has enabled him to form his own opinions." It seems strikingly apparent throughout the fifteen chapters comprising this volume that the foundations for beliefs are built of personal experience. Yet one cannot help but feel that the superb teachings of Ker have exerted a profound influence on the concepts in the text.

There is little discussion regarding individual patients or series of cases which are likely to be recorded in a contagious disease hospital and with which the medical superintendent would be familiar. Statistics are surprisingly few. For the most part the opinions expressed are sound and practically identical with those adhered to in fever hospitals elsewhere. In America, however, there are some who will not agree that a lumbar puncture "is necessary in cerebrospinal fever . . . for the relief of pressure." And for other conditions the use of poultices and mustard baths would be frowned on in most contagious disease hospitals of this country.

The best chapters are those which concern scarlet fever, diphtheria and smallpox. There is no bibliography, but the works of many authors are quoted, with the years in brackets. Though the great majority of these references extend back ten years or more, there is little to criticize on the ground of incompleteness. There is a chapter on puerperal sepsis and one on enteric fever, but no reference is made to poliomyelitis. Practically all of the other common contagious diseases are described.

The book is convenient in size. The various topics are set forth in a concise manner and follow closely opinions held by many who have made an extensive study of the acute infectious diseases. The volume should be helpful to the medical student but valued more highly by the resident and appreciated most by the experienced medical officer. There are a number of excellent photographs illustrative of such diseases as smallpox, scarlet fever and measles, also tables and numerous fever charts.

Chirurgie der Infektionen mit weitgehender Berücksichtigung der Behandlung. Von Prof. Dr. Rudolf Demel, Vorstand der II. Chirurgischen Abteilung der Krankenanstalt "Rudolfsstiftung" in Wien. Cloth. Price, $18. Pp. 659, with 181 illustrations. Grune & Stratton, Inc., 443 Fourth Ave., New York 16; Wilhelm Maudrich, Spitalgasse 1B, Wien IX/2, 1947.

The author points out in the preface that the surgeon must rely on his experience more when treating infectious processes than other conditions because the correct appraisal of the virulence of bacteria and the resistance of the invaded organism can be learned only from numerous observations. It is this experience that he tries to share with his readers.

The first part of the book deals with classification of infections, choice of anesthesia, preoperative treatment and postoperative care, while the second part is formed by description of surgical procedures in topographical order.

Perusal of the book detects numerous deviations from popular concepts and from the use of therapeutic measures in vogue in the United States. Regional ileitis is not mentioned. Newer sulfonamide compounds such as sulfathalidine and sulfasuxidine, also amino acids, dicumarol, heparin, menadione and absorbable sponges apparently are not being used by the author. Some methods are at distinct variance with those commonly used in the United States. One mg. (1/60 grain) of atropine preoperatively seems to be a rather large dose. In acute pancreatic necrosis the author recommends the drainage of the hepatic duct in preference to that of the gallbladder. To avoid tears during the removal of the drain, with the resulting fistula formation or cicatrical stenosis, the author uses a Nelaton catheter instead of a T tube for the drainage of the common duct. No distinction is made between thrombophlebitis and phlebothrombosis. For some obscure reason gastric resection and gastroenterostomy have been included in the text, although it is difficult to conceive what infections can necessitate such operations.

The book contains much practical material, offers sound advice and points out common errors. The illustrations, some in color, are numerous and instructive. The book should be of great interest to a seasoned, critical reader, if for no other reason than out of curiosity to see what is doing in medicine in a country ravaged by war.

Gynecology with a Section on Female Urology. By Lawrence R. Wharton, Ph.B., M.D., Assistant Professor of Gynecology, The Johns Hopkins Medical School, Baltimore, Maryland. Second edition. Cloth. Price, $10. Pp. 1,027, with 480 illustrations. W. B. Saunders Co., West Washington Square, Philadelphia 5, 1947.

The second edition of Wharton's book contains only a few changes in the text and a number of new illustrations. However, there is nothing wrong with this fact because the first edition was an excellent book and there have been no changes in the field of gynecology during the last four years which would demand radical changes in the book. The progress which has been made is indicated by the author because all the subjects including chemotherapy are brought down to date. In the large and excellent section on female urology, a chapter has been added on water cystoscopy, and the subject of the female urethra has been given a separate chapter. The present edition, like the first one, contains a large number of borrowed illustrations, but all of them are beautiful and instructive. The book is well written, the material embraces all the important phases of gynecology and female urology and the text and illustrations are clearly printed on good paper.

Diagnóstico y terapéutica quirúrgicos de urgencia. Por el Dr. F. Doménech-Alsina. Fabrikoid. Pp. 912, with 330 illustrations. Salvat Editores, S. A., 371 Lavalle, Buenos Aires, 1947.

This will be an excellent textbook for medical students who are desirous of getting acquainted with the European concept of modern emergency surgery. The treatment for burns and gas gangrene is excellently outlined and very logical. The chapter on brain and cranial injury is weak compared with the works of Cushing, Naffziger, Glasser and others. However, the book covers well the particular types of injuries it discusses. It gives some original approach to the problems of thoracic surgery which reflects the fruition of the Spanish civil war experience. Our own textbooks on thoracic surgery, as a whole, are better. The author draws extensively from his vast experience obviously gained during the two wars—especially during the Spanish civil war of some ten years ago. Concise and explicit directions are given for tendon and nerve surgery. Although the chapter on acute conditions of the abdomen falls short on diagnosis, it more than compensates in its therapeutic and surgical approach. The treatment of acute peritonitis is rather drastic and unlike ours. Sulfonamide drugs and penicillin are sparsely used, although these drugs are recommended in other septic cases taken up in the text. Streptomycin is not mentioned. Some rare abdominal lesions with acute syndromes are skilfully treated in the text, with excellent analytic and diagnostic approach. The various lesions incident to hand injury, including nerve and tendon sutures, are well covered. The chapter on urologic lesions is not sufficiently inclusive to be further informative to seasoned American urologists. It is, however, very pertinent for general surgeons. Although the index is poorly done, this is a good book for general surgeons and a quick reference work for surgical emergencies.

Handbook of Medical Emergencies. Thomas B. Fitzpatrick, M.D., Chairman, Contributors. Cloth. Price, $2.50. Pp. 106. Harvard University Press, Cambridge 38; Oxford University Press, Amen House, Warwick Sq., London, E. C. 4, 1947.

Although the methods, drugs and dosages used in hospitals for each of the various kinds of medical emergencies vary, the intern and the resident often find need for a compendium which provides a sound pattern. This handbook, prepared with consultative help from faculty members, presents procedures for each emergency, step by step in outline form—drugs to be used and their dosages, supportive therapy and other indicated measures. Diagnostic criteria for some of the emergencies and suggested procedures to establish the diagnosis are presented. Opposing pages throughout the book are left blank, so that treatment changes or other notes can be recorded readily. There are sections dealing with penicillin and sulfonamide therapy, intoxications, infectious diseases, diseases due to allergy and to physical agents, and diseases of the various body systems. The longest sections are, appropriately, on intoxications, cardiovascular emergencies and neuropsychiatric diseases. Examples of specific topics discussed are laryngeal infection, meningitis, Jarisch-Herxheimer reaction, serum accidents, acute agranulocytosis, barbiturate poisoning, botulism, acute hepatic insufficiency, peripheral arterial embolism, addisonian crisis, congestive heart failure and transfusion reactions. Tables of equivalents and of normal blood, urine and spinal fluid values are provided. This excellent handbook fits snugly into the intern's coat pocket. It should be helpful to the young practitioner as well as to the hospital physician, for it contains a wealth of immediately useful information. The Harvard University Press and the faculty deserve congratulation for encouraging the authors to embark on medical writing projects early in their careers periods of six to eight months. This study is not conclusive because it is based on totally inadequate data to support the claims made. Until more convincing data are presented, therefore, the use of fluorides in dentifrices, mouthwashes, tablets and lozenges cannot be recommended."

It would appear, therefore, that at the present time there is no acceptable scientific evidence adequately controlled which would indicate that fluoride tablets taken by adults will or will not reduce the incidence of dental caries.

TESTOSTERONE AND ARTERIOSCLEROSIS

To the Editor:—Of what benefit is testosterone in the treatment of arteriosclerosis? Is there not an element of danger? My patient cited the advice of a physician who also felt the androgenic hormone would help his anginal attacks. This patient insisted his nocturnal micturition was abolished by the use of this agent.

Paul W. Van Metre, M.D., Rockwell City, Iowa.

Answer.—Thus far convincing evidence has not been elicited that testosterone affects arteriosclerosis either beneficially or adversely. Arteriosclerotic changes start many years before they become clinically manifest, and it is highly unlikely that the processes are appreciably reversible. Arteriosclerosis in women is not affected by estrogenic therapy; there is little likelihood that the same disorder in men will be significantly benefited by androgen administration. The symptoms of the male climacteric, which usually occur somewhere between 55 and 65 years, are vague and indefinite: anxiety, indecisiveness, apokamnosis, hyperhidrosis, insomnia and the like. These may or may not be as much of psychogenic origin as due to hormonal depreciation, for at these years profound changes in social status and social security are apt to occur. Retirement, the dissolution of the family by marriage of children, loss of potency and diminution of the signs of respect from younger competitors in vocational fields all contribute to the emotional instability which is the predominant sign of the male climacteric. It is claimed that testosterone is of great value for these patients, but one must be skeptical and consider also the element of psychologic effect.

The dangers of testosterone are insidious and therefore all the more significant. Prostatic hypertrophy is accelerated and there is some evidence (not absolutely convincing as yet) that androgens may accelerate conversion of prostatic hyperplasia into cancer. Certainly the growth of prostatic carcinoma is accelerated. In the light of present knowledge, testosterone is probably not indicated in the management of arteriosclerotic disease.

PROLONGED PNEUMONIC CONSOLIDATION

To the Editor:—A patient has delayed resolution from lobar pneumonia. This is the second case of this kind I have had in the last twenty years. My treatment of the first case was unsatisfactory. The second case seems to be following the same course. Is there any treatment or way of handling this type of case that promises a cure?

H. I. Blood, M.D., Hazel Green, Ky.

Answer.—The question cannot be answered satisfactorily without information about the clinical course. Delayed resolution may imply simply a delay in the absorption of the infiltrate or exudate in the lung without subjective symptoms, which needs no treatment and usually clears up in time. If the term delayed resolution is used synonymously with unresolved pneumonia, a common error, it implies a continuation of the disease. In the case of pneumococcic lobar pneumonia, this occurs without explainable reason in rare instances even after proper treatment. Often, however, some other process is present such as bronchiectasis, abscess, foreign body or neoplasm. In viral pneumonia the course may last three or more weeks before resolving. Effort should be made to determine the type of pneumococcus involved in the first place and if any of the complications mentioned are present before proper therapy can be given.

HEMATOCRIT VALUES IN CHILDREN

To the Editor:—Would you give me the hematocrit values of normal children according to the age, ranging from birth to six years?

M.D., Buffalo.

Answer.—The hematocrit values for children vary greatly and do not have significance except in relation to the red cell count. At birth and during the first few days of life the hematocrit values are higher than the red cell count because of the fact that the mean volume of the red cell is larger than normal. The cell soon returns to normal, however.

COSMETIC EFFECT AFTER REMOVAL OF FACIAL CYST

To the Editor:—The answer to the query in The Journal July 19, 1947, page 1056, concerning the removal of a sebaceous cyst from the face with minimum postoperative scarring can be improved on. For years, in all wounds of the face, as well as in the incision for the removal of goiter, I have used a subcuticular suture of 000 iodine catgut. No stitch holes are made in the skin, the suture is absorbed, no dressing is used, and the resulting scar is less than by any other method.

John D. Singley, M.D., Pittsburgh.

To the Editor:—A simple, successful and nonscarring procedure to treat sebaceous cysts has been used in my practice for eighteen years and in dozens of cases. The advantage of the procedure is seen especially in sebaceous cysts which involve the entire ear lobe or which have been repeatedly infected and are thereby rendered more recalcitrant to surgery. Anesthesia consists of an intradermal wheal in the roof of the cyst with 1 per cent procaine, then forcible injection with considerable pressure of the anesthetic solution into the cyst sac. This anesthetizes the proposed point of incision and the wall of the cyst sac. The latter portion of the anesthetic maneuver is important. With the actual cautery, fulgurating point or a blunt or sharp instrument a small opening is made into the cyst and the retained sebum is then completely expressed. With a dry cotton applicator the interior of the cyst scar is dried, multilocular extensions explored and evacuated, and all sebaceous material removed. A cotton applicator soaked with liquefied phenol (95 per cent) is then inserted and all surfaces of the cyst sac are thoroughly cauterized. The skin about the incision is protected with frequent applications of 70 per cent alcohol on a cotton sponge. After five minutes the phenol within the sac is neutralized with alcohol, A drain is then inserted and changed each day tor two or three days. The wound is then permitted to heal. Sometimes the cyst sac presents at the incision on the second day and may be extracted, but this is not important as it will be absorbed. If properly done this will eradicate 100 per cent of sebaceous cysts without unsightly scarring.

Hiram D. Newton, M.D., San Diego, Calif.

To the Editor:—In The Journal, July 19, the question is asked as to the best method of removing a sebaceous cyst from a girl's face without leaving a scar. The answer states "There is no way possible to remove a cyst of this type without an incision through the skin," apparently evidencing unfamiliarity with the method described by Joseph A. Danna (*New Orleans M. & S. J.* 98:5 [July] 1945). By this technic a needle is inserted into the cyst and the unipolar desiccating current applied. I have treated sebaceous cysts by this method with uniform, complete obliteration and no resultant scar.

Norman R. Goldsmith, M.D., Lancaster, Pa.

To the Editor:—In The Journal July 19 the answer to the query on "Cosmetic Effect After Removal of Facial Cyst" is incomplete. It is misleading also because an "incision" in the ordinary sense of the word is not necessary for the cure of this lesion. Formerly it was believed that sebaceous cysts were formed by the blocking of outlets of otherwise normal sebaceous glands. Whether or not this is true, they can be cured by making artificial outlets provided the new outlets are made in a manner to insure their remaining open for a month or longer. I use the high frequency cutting current from a vacuum tube type of machine and make a hole about 0.5 cm. in diameter (larger for large cysts) which penetrates the skin and the sac. It remains open for a sufficient length of time for the sac to atrophy or regress to about the size of a normal sebaceous gland. When this occurs, it usually appears about like the hole remaining after extraction of a blackhead. This method is especially applicable in a case such as the one described, because the preceding infection would make removal in toto by sharp dissection rather difficult and productive of further scarring. This method is not new and it has certain disadvantages. A somewhat longer time is required for cure and some surgical judgment is required, as too small a hole will close prematurely, while an unnecessarily large one makes a conspicuous scar; but in my opinion the advantages far outweigh the disadvantages.

Lyman C. Blair, M.D., Houston, Texas.

To the Editor:—In Queries and Minor Notes in The Journal of July 19 Willis P. Baker of Santa Ana, Calif., inquired how to remove a sebaceous cyst from the face with a satisfactory cosmetic result. I should like to call attention to a method advocated by Dr. Joseph A. Danna in the *New Orleans Medical and Surgical Journal* 98:5 (July) 1945 in an article entitled "A Simple Treatment for Sebaceous Cyst." While I have used it since 1939, Dr. Danna is entitled to full credit for publicizing this effective method which consists in anesthetizing the high point of the cyst with procaine or some other local anesthetic and then inserting a fine needle into the cavity at this thinnest point. The current is then applied until a whitish eschar forms at the needle. The contents are then forcibly expressed. The cyst grows smaller and smaller until it eventually levels off with the skin. One treatment is usually enough for cysts up to 3 cm. but several punctures may be used for larger cysts. The cosmetic result is excellent if properly done.

Edwin Matlin, M.D., Mount Holly Springs, Pa.

To the Editor:—The answer to the query on Cosmetic Effect After Removal of Facial Cyst fails to mention utilization of the monopolar high frequency current. A technic of long standing and certainly widely known is to place the needle of a high frequency machine Oudin current into the cyst. The current soon softens the sebaceous material content, which is released when the needle is withdrawn. Further current on reinsertion of the needle into the first aperture loosens the sac. Very little traction with a forceps permits the withdrawal of the sac through the same opening. No suture is required. The scar is small. Sebaceous cysts of the face and scalp have been removed by this method over the past twenty years. The results are excellent. Local anesthesia is not required. The high frequency apparatus must be of the type permitting current flow from its Oudin coil with the needle inserted into the cyst. Some apparatus fails in this important feature of the method.

PRIMARY CANCER OF THE LUNG

Chairman's Address

ALTON OCHSNER, M.D.
MICHAEL DeBAKEY, M.D.
and
J. LEONARD DIXON, M.D.
New Orleans

Within the past few decades two well established and generally accepted concepts of primary cancer of the lung have been completely disproved. One is the concept that carcinoma of the lung represents the "rarest form of disease." [1] The other is the concept that pulmonary cancer is a hopeless condition. The present, completely antithetic concepts came about in the first instance through intensive and more accurate studies, which demonstrated that the lung is second in frequency only to the stomach as a primary site of malignant growth, and in the second instance through the pioneering achievement of Evarts Graham,[2] who showed fourteen years ago that resection of a primary pulmonary neoplasm is possible. This successful achievement contributed still further stimulation to studies on the incidence of the disease. In many respects these facts reflect the rapid progress which has taken place in this relatively short time in the field of thoracic surgery.

Our surgical experience with carcinoma of the lung covers a period of approximately twelve years, during which 412 patients with this disease were observed on the Tulane University School of Medicine service in Charity Hospital of Louisiana at New Orleans and in private practice at the Ochsner Clinic. Of the 412 patients, 246 underwent surgical exploration, and of the 246, 147 were subjected to primary pulmonary resection. This article is based on an analysis of the experience described, with particular emphasis on follow-up studies, which were carried out in all patients who submitted to primary resection.

INCIDENCE

In the recent literature much emphasis has been placed on the apparently increasing incidence of carcinoma of the lung. This phase of the subject has been extensively reviewed in previous publications.[3] Although some observers have expressed the opinion that this increase in incidence is actual, others believe that it is only apparent. However, the important practical consideration is that virtually all observers *who have analyzed the experience in their institution* over a long period of time have found a definite increase in the incidence of this disease. It now appears to be one of the most frequently encountered malignant neoplasms, being preceded only by the stomach as a primary site of cancer.

Our experience in the Charity Hospital of Louisiana at New Orleans supports these observations. During the ten year period ending Dec. 31, 1945 the annual incidence of carcinoma of the stomach, although showing transient changes, remained about the same, whereas the incidence of carcinoma of the lung revealed a steady rise. Suggestive of a racial factor is the fact that this increase in incidence occurred primarily among white patients, with little or no change among the Negro patients. This observation obtains further support from a comparison of the racial incidence of carcinoma of the lung and stomach with all admissions. Whereas the ratio of white to Negro patients is about 2 to 3 for carcinoma of the stomach and perhaps not significantly different from that for all admissions, for carcinoma of the lung this ratio is practically reversed, being 2 to 1 in favor of the white race. Although the white preponderance is even more striking among the patients in whom pneumonectomy was performed, this is readily explained by the large proportion of patients who were treated at hospitals which serve only white patients.

It has long been recognized that carcinoma of the lung is predominantly a disease of the male sex, an interesting but unexplained fact. In our series of 412 cases there were 356 (86.4 per cent) in men and 56 (13.6 per cent) in women. Of the 147 patients in whom pneumonectomy was performed, 121 (82.3 per cent) were men and 26 (17.7 per cent) were women. These figures conform closely with those obtained in a series of 8,575 collected cases in which 6,769 patients (78.9 per cent) were men and 1,806 women (21 per cent).[3a]

Carcinoma of the lung, like other carcinomas, occurs most frequently in the fifth, sixth and seventh decades of life. Approximately 90 per cent of the patients in

both our total series as well as in the cases of resection were in this age group. The youngest patient in this series was 12 years of age, and the oldest was 81.

ETIOLOGY

The apparent increase in the incidence of carcinoma of the lung stimulated much speculation concerning its cause. The numerous explanations advanced to account for this fact have been reviewed in previous publications.[3] In the analysis of this series none of these factors was found to bear a significant relation to the occurrence of the disease. Both occupation and smoking, which have been particularly emphasized by some observers as possible etiologic factors, and which we were inclined previously to consider more seriously, were found to have no special significance in his analysis. Of the 147 patients in whom pulmonary resection was performed 76 per cent were smokers and 24 per cent were nonsmokers, and the number of those who had indoor occupations was almost equal to that of those who did outdoor work.

PATHOLOGY

Most primary tumors of the lung are malignant, and with few exceptions they are bronchiogenic in origin. Recently, Ikeda[4] has called attention to the occurrence of alveolar carcinoma of the lung, which differs from most pulmonary carcinomas in that it occurs with equal frequency in both sexes and originates in the alveoli rather than in the bronchi. There is a good deal of variation in the pathologic types of bronchiogenic carcinoma. They will not be discussed here, because they will form the subject of a subsequent report. Of the 147 cases of resection, there were 141 cases of bronchiogenic carcinoma, 2 cases each of fibrosarcoma and lymphoblastoma, and 1 case each of melanoma and neurogenic sarcoma. The right lung is involved somewhat more frequently than the left in primary cancers of the lung. In a series of 4,732 cases which we[3a] previously collected from the literature, there were 2,761 (58.3 per cent) tumors involving the right lung and 1,971 (41.6 per cent) involving the left lung. In the present series of 147 cases of primary pulmonary cancer in which pulmonary resection was done, the right side was involved in 87 cases (59 per cent) and the left side in 60 (41 per cent). The upper lobes of both lungs and the lower lobe of the right lung were involved in 11.6 per cent of cases. The fact that the upper lobes in our operative series were involved so frequently is significant because of the difficulty in bronchoscopic visualization and biopsy of these lesions.

CLINICAL MANIFESTATIONS

Because of the paucity of symptoms, particularly in the earlier stages, and the usually insidious onset, it is difficult to portray a characteristic clinical picture of carcinoma of the lung. These factors undoubtedly account for the frequent delay in diagnosis. In the present series of 147 cases of resection, the commonest symptoms were cough, loss of weight, pain or discomfort in the chest, a history of a previous respiratory infection, hemoptysis and dyspnea in about that order of frequency. Not infrequently only one or two of these manifestations are present, and occasionally the patient has no symptoms, the diagnosis being made from a routine roentgenogram of the chest. Cough is particularly difficult to evaluate because it may so frequently be explained as due to smoking. For this reason it is particularly important to distinguish any change in the cough and to determine any associated thoracic symptoms of recent development. Another manifestation which deserves some consideration is a history of a previous respiratory infection. Instead of prompt and complete recovery after such an infection the symptoms persist. Too frequently the significance of this is not appreciated until several months have elapsed, and then proper studies reveal the true diagnosis.

The physical observations in carcinoma of the lung are also variable and, like the symptoms, are generally not characteristic, especially in the earlier stages. They depend on the site, size and direction of growth of the tumor. Significant manifestations are more likely to be encountered if the tumor encroaches on the lumen of larger bronchi or on the pleura. A relatively small tumor completely occluding a main stem bronchus will produce impressive physical evidence, because of the atelectasis which follows the bronchial obstruction. On the other hand, a peripherally located tumor of considerable size which does not cause obstruction to a major bronchus or encroach on the pleura may produce relatively few physical symptoms.

DIAGNOSIS

The most important factor in the diagnosis of primary pulmonary neoplasms is the consideration of its possible presence. As emphasized previously, primary carcinoma of the bronchus should be suspected in every man over 40 years of age who has unexplained thoracic discomfort, a persistent cough or hemoptysis. This is the key to increasing the incidence of early diagnosis.

The important diagnostic methods include roentgenographic, bronchographic, bronchoscopic and cytologic examination of the sputum or bronchial secretions. Roentgenography is of great value in the diagnosis of bronchiogenic lesions, although in the early, nonobstructing lesions the roentgenogram may show no change. Serial roentgenograms are of particular value in the early stages by revealing an increase in the size of the shadow. Not infrequently, relatively small lesions will occlude a large bronchus and produce atelectasis of the lung distal to the point of occlusion. In such an instance a shadow much greater than one would expect from the size of the neoplasm will be seen in the roentgenogram. For this reason an opacity of considerable size does not necessarily signify actual invasion of the lung to that extent but may simply indicate a collapsed atelectatic lung. Centrally located lesions are often difficult to diagnose radiologically because of the confusion with hilar shadows produced by other lesions and by normal structures. Here again, the use of serial roentgenograms is of importance to determine the progress of the lesion. Occasionally, a relatively small lesion in the periphery of the lung will produce a large hilar shadow because of involvement of the mediastinal nodes, the shadow produced by the nodes being much larger than that of the originating lesion. Because of the stasis produced in an area of the lung drained by a bronchus which is occluded by the tumor or because of interference with the blood supply in the center of a rapidly growing tumor, necrosis and infection of the lung may occur with the production of a pulmonary abscess or bronchiectasis. In fact, in a man past 40 years of age an abscess of the lung which cannot be otherwise explained satisfactorily should always be considered of carcinomatous origin until

disproved. Roentgenographically, pulmonary abscess associated with bronchiogenic cancer not infrequently is evidenced by an irregularity of the wall of the abscess because of the neoplastic tissue which extends into the abscess cavity. Tomographic examination is of value in these cases because of the better visualization and the sharper delineation of the walls of the cavity. Roentgenographic examination of the chest should be performed routinely both because it can be done so simply and because it yields such good results. The importance of routine roentgenograms is shown by the fact that the growth, which was producing no symptoms and consequently was not suspected, was discovered as a part of the routine examination in 5 of our 147 cases in which pulmonary resection was done for carcinoma of the lung. In 121 of the 147 cases (82.3 per cent) the roentgenographic diagnosis was bronchiogenic carcinoma. The diagnosis of pulmonary abscess in 8 cases (5.4 per cent) was the most frequent error, but in almost every case an abscess was actually present in association with the carcinoma.

Although bronchographic study is not essential in all cases of bronchiogenic carcinoma, it is a valuable diagnostic aid in some instances. This is particularly true in lesions located in the periphery of the lung and in those which involve the bronchi of the upper lobe. In the peripherally located bronchi and in the bronchi of the upper lobe which are beyond the vision of the bronchoscopist, visualization of an obstruction in a bronchus is confirmatory evidence of a primary neoplasm. In our series of 147 cases of pulmonary resection, bronchographic examination was performed in 69 (47 per cent).

Of all the diagnostic methods, bronchoscopic examination with biopsy is the most accurate, because this procedure frequently not only permits direct visualization of the tumor but also the section of a piece of tissue for microscopic examination. Unfortunately, the procedure is of no value in a large group of cases because of the peripheral position of the tumor beyond the vision of the bronchoscopist or more frequently because of its position in the bronchi of the upper lobe, i. e., "around the corner," which precludes visualization by routine bronchoscopic methods. By means of a mirror or a special bronchoscope which permits periscopic visualization, many of these tumors can be seen, but biopsy is not possible. At times the induction of artificial pneumothorax by permitting the upper lobe to fall will bring the upper lobe bronchus in more direct line with the main stem bronchus and will permit visualization of an upper lobe bronchus which would not be visible otherwise. In our 147 cases in which pulmonary resection was performed for cancer, bronchoscopic examination was done in 125 cases. In the remaining group, the procedure was not used because of the peripheral location of the tumor. In the 125 cases in which bronchoscopic examination was performed a specimen for biopsy was obtained in 74 (59.2 per cent) with a positive diagnosis in 61 (82.4 per cent). Thus, of 147 cases of cancer of the lung treated by pulmonary resection, a positive diagnosis was obtained by bronchoscopic biopsy in 61 (41.5 per cent). This figure is somewhat lower than many of those reported by others in which a correct diagnosis was made bronchoscopically in as high as 60 to 75 per cent. Our lower incidence (of positive diagnosis by biopsy) may be due to the fact that operative intervention was performed on a large number of patients in whom the lesions were not visible bronchoscopically; although a positive preoperative diagnosis could not be made, the patient was not denied the advantage of operative treatment. This is supported by the fact that the lesion was in the upper lobes in almost half (49 per cent) of our cases of resection.

Another important diagnostic procedure, and one which may prove with increasing experience to be the most important, is cytologic examination of the sputum or bronchial secretions. It is particularly useful in cases in which the tumor is beyond the range of bronchoscopic visualization. From the reports in the literature the method is proving increasingly successful.[5]

The demonstration of tumor cells in the pleural fluid is also of diagnostic value. However, this method is of more prognostic than diagnostic significance; although the presence of tumor cells in the pleural cavity verifies the diagnosis, it usually indicates a hopeless prognosis.

Although Craver[6] has been an ardent advocate of aspiration biopsy in bronchiogenic carcinoma, we believe that this method should not be used in a patient in whom there is a possibility of resection but should be limited to cases in which operative intervention appears definitely contraindicated. A positive diagnosis frequently can be made following aspiration biopsy, but the procedure is undesirable because of the danger of implantation of tumor cells in the tissues traversed by the biopsy needle. We have seen 3 patients in whom implants have occurred along the site of the aspirating needle, a cure being precluded because of the implanted carcinoma on the thoracic parietes, and this complication has been reported by others.[7]

Although an exploratory operation possibly cannot be considered as a diagnostic procedure, it is our belief that in a man past 40 years of age with an unexplained thoracic complaint in whom the existence of a bronchiogenic neoplasm can be neither disproved nor verified, exploration of the chest is justified, especially since the risk is now minimal. Previously, we believed that an operation was not justified unless a positive diagnosis could be made preoperatively, but had we continued to adhere to that contention, we would have denied a number of patients an opportunity for cure. In our series of 246 cases in which an exploratory operation was performed, a positive diagnosis was established prior to operation in 164 (66 per cent).

TREATMENT

The treatment of primary cancers of the lung consists ideally of extirpation of the involved lung before the lesion has extended beyond the confines of the lung. Extirpation of the process offers the only cure. Whereas occasionally a patient may be benefited by irradiation, generally the results from this form of therapy are of little or no value. It may be used as a palliative procedure and may be of value in hopeless cases in the alleviation of symptoms. Certainly, in view of our present knowledge, it is not justifiable to use roentgen therapy in early and operable lesions. Recently, the use of nitrogen mustard, methyl-*bis*(beta-chlorethyl) amine hydrochloride, has been reported to be of possible value in alleviating symptoms in inoperable cases, but we have had little experience with its use.

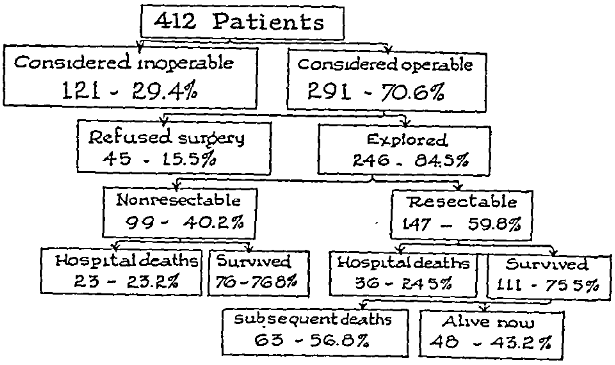
Contraindications to exploration, we believe, are relatively few. Involvement of the phrenic and recurrent laryngeal nerves has been considered by some a definite contraindication to exploration, but we do not share this opinion. Although in many instances these cases will prove inoperable, we have repeatedly seen persons with this type of involvement in whom at exploration it was possible to resect the lesion. Our indications of definite inoperability are distant metastases, obvious involvement of the carina or trachea and the observation of malignant cells in the pleural fluid. Every other patient should be given the advantage of thoracic exploration, because only in this way can one determine whether the lesion is operable.

The desideratum in the treatment of bronchiogenic carcinoma is curative resection of the lung. However, we are of the opinion that in many instances palliative resection is justified. Even though the patient may subsequently succumb to extension of the malignant process, removal of the involved lung with its contained tumor, which has undergone necrosis and which has become infected with the development of an abscess, is sufficient justification for the procedure. The remaining days of the patient's life are made more comfortable, and he is spared the sepsis and the continued exudation which would have existed had the lung not been removed. We appreciate the fact that there may not be complete agreement with this point of view, but it seems to us justifiable on a purely humanitarian basis. Moreover, as will be observed later, the survival periods following palliative resection seem to be sufficiently long to justify operative therapy.



412 Patients
Considered inoperable 121 - 29.4%
Considered operable 291 - 70.6%
Refused surgery 45 - 15.5%
Explored 246 - 84.5%
Nonresectable 99 - 40.2%
Resectable 147 - 59.8%
Hospital deaths 23 - 23.2%
Survived 76 - 76.8%
Hospital deaths 36 - 24.5%
Survived 111 - 75.5%
Subsequent deaths 63 - 56.8%
Alive now 48 - 43.2%

Fig. 1.—Schematic representation of results in present series of 412 cases of pulmonary cancer.

No attempt will be made here to discuss technical considerations of the operation, since they have been presented elsewhere.[8] We are still of the opinion that with few exceptions pneumonectomy is the procedure of choice because it permits more thorough extirpation of the involved tissue and the possibly involved hilar lymph node.[9] Simple lobectomy was performed in only 2 of the 147 cases of resection, in 1 because at the time of operation the condition was thought to be inflammatory (this patient has remained well for over five years), and in the other as a palliative procedure. Both the anterior and the posterolateral approaches have been used, but in general the former is preferred because it has seemed to us to have certain advantages over the latter and because it has proved technically satisfactory.

ANALYSIS OF RESULTS

Of the 412 cases reported in this paper, 246 patients (59.7 per cent) were operated on and 166 (40.3 per cent) were not operated on (fig. 1). The latter number includes 121 (29.4 per cent) cases which were considered clearly inoperable at the outset and 45 in which the lesion was considered operable but the patients refused surgical treatment (fig. 1). Of the 246 lesions which were explored, 99 (40.2 per cent) proved to be nonresectable and 147 (59.8 per cent of the number explored, or 35.7 per cent of the total series) were resected. In other words, of every 3 cases of clinical pulmonary cancer 2 will appear to be operable and only 1 will prove to be resectable. Although these incidences are somewhat higher than those found in a collected series of 2,034 cases (29.2 per cent for exploration and 13.4 per cent for resection), they are in accord with those appearing in the more recent reports which reflect an encouraging trend toward higher incidences.[10] However, they are still much too low and emphasize the need for wider recognition of the problem and for earlier diagnosis.

Of the 99 patients in whom the tumor was not resectable, 23 died in the hospital (23.2 per cent) and 76 (76.8 per cent) left the hospital alive. Of the 147 patients in whom resection was performed, 36 (24.5 per cent) died in the hospital and 111 (75.5 per cent) left the hospital alive. Of the latter group, 63 (56.8 per cent) have subsequently died and 48 (43.2 per cent) are still alive, 1 of whom was operated on eleven years ago.

An analysis of the resectable tumors according to whether operation was performed before or after 1942 shows the hospital mortality for these periods to be 46.4 per cent and 19.3 per cent, respectively. It may be reasonably assumed that the lower mortality rate in the later period is due to better operative technic and better preparation and postoperative care of the patient. The relatively high operative mortality for the entire series (24.5 per cent) is, we believe, due in great measure to the fact that resections were performed in patients with extensive disease as well as in those with poor cardiovascular function. This is illustrated by the fact that in order to resect the lesion which had extended beyond the confines of the lung it was necessary to ligate the pulmonary vessels in the pericardium in 18 cases (12 per cent), to resect and suture a portion of the auricle in 8 (5 per cent), to resect a portion of the diaphragm in 9 (6 per cent) and to resect a major portion of the chest wall in 8 (5 per cent). Earlier in our experience many of these cases would have been considered inoperable, but we now believe that the limits of operability can be extended by these procedures and that the effort is justified in order to give the patient his only chance of relief.

The postoperative complications were principally empyema and a blown bronchus. In 18 (12.2 per cent) of the 147 cases empyema developed, and in 8 of these

(5.4 per cent of the entire group) the bronchus opened. It is our general impression that chemotherapy, whether in the form of sulfonamide drugs or penicillin, has not materially influenced the incidence or the morbidity of these complications.

Further evidence of improvement in the surgical management of these cases with increasing experience is shown by a consideration of the morbidity rate and the length of hospitalization in the patients treated before January 1942 and those treated since that date. In the former group the longest hospital stay was 107 days, the shortest 11 days, and the average 32.3 days. In the latter, the longest period of hospitalization was 118 days and the shortest 6, with an average of 13.5 days. It would seem that the decrease in the hospital stay in the later period is a reflection of better preoperative preparation and more effective postoperative care.

Of the patients who died in the hospital, death occurred within the first twenty-four hours in 33 per cent, from the first to the fifth day in 19.4 per cent, from the sixth to the tenth day in 22.2 per cent, from the eleventh to the fifteenth day in 11.1 per cent and on the eighteenth day in 1 case, and 4 died on the forty-third day. In the 36 cases which ended fatally within the hospital, cardiovascular lesions were responsible for the fatality in 47 per cent. The fact that almost half of the hospital deaths were the result of cardiovascular lesions has prompted us to include a cardiologist in our thoracic team in order to observe these patients preoperatively and postoperatively. It is our belief, however, that the incidence of this cause of death will not be greatly reduced unless the criteria of operability are so strictly limited that patients in whom this complication is likely to occur are excluded from surgical treatment and are thus denied what is admittedly their only chance of salvage.

SURVIVAL RATES

In the evaluation of any form of therapy follow-up studies are essential, and this is particularly true for malignant disease. In this series of 147 cases in which resection for pulmonary cancer was done, every patient who was operated on six months or more ago has been followed to date, in the majority of instances the postoperative examination being made by one of us. Because the 123 patients who had been operated on six months ago or longer were treated surgically at varying periods of time during the past eleven years, the number of cases in each category is different, and the numbers become smaller as the possible survival time increases. Patients operated on only a year ago, for instance, obviously have had no opportunity to survive longer than a year. Of the 123 patients operated on six months or more ago, a little over half survived the first six-month period after operation (fig. 2). The 55 deaths in this period, however, include the 36 deaths which occurred in the hospital immediately after the operation. Slightly less than three fifths of the patients, again including those who died in the hospital, died within the first year. After that time, however, the death rate increased much less rapidly. At the end of five years approximately one fourth of the patients (23.3 per cent) who had submitted to resection were still alive (fig. 2). To express it differently, the distribution curve for the survival rate drops rather rapidly within the first two years after operation, but by the third year it becomes stabilized and continues almost as a plateau until the fifth year. It is obvious that a patient with carcinoma of the lung who has survived pneumonectomy for two years has a good chance of being alive at the end of five years.

If hospital fatalities are excluded and an analysis is made only of those patients who left the hospital alive, the distribution curve is similar to the curve for the entire group but is simply at a higher level and thus appears more encouraging; the survival rate at the end of five years then reaches 44 per cent as contrasted with 23.3 per cent when all the patients are included (fig. 2).

Unfortunately, as has already been indicated, there was a large number of cases in this series in which there was gross evidence of extension to other structures, such as the mediastinal lymph nodes or the adjacent viscera. Obviously, when such extension has occurred the chance of a cure is considerably less, because once there has been involvement of the adjacent structures the possibility of removing all the tumor cells, even though these structures are resected, is reduced. Therefore we divided the cases into two groups: those in which there was no gross evidence of extension beyond the lung at the time of operative intervention and those in which the other structures were involved. As was expected the survival rate among the patients with localized growths was significantly greater than that for patients with extension, the figures being 42.9 per cent and 6.2 per cent, respectively, at the end of five years (fig. 3).

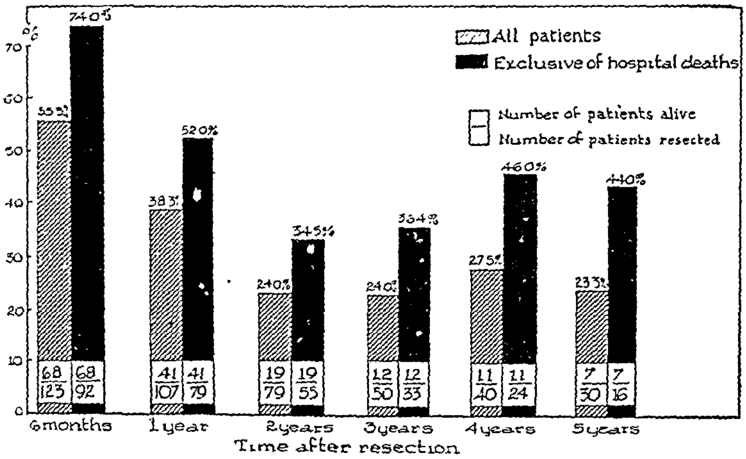

Fig. 2.—Survival rate after resection in present series of pulmonary cancer.

Since with increasing experience there has been definite improvement in the operability, hospital mortality and morbidity of pulmonary resection for carcinoma of the lung, it was considered possible that similar improvement might be reflected in the survival rates. Accordingly, the material was analyzed with this objective in mind, the cases having been divided into two groups, depending on whether operative intervention was performed before or after 1942. The analysis of the whole group, as well as the localized and the nonlocalized lesions, reveals no [illegible]t diffe ences in the survival rates before and after 1942. It would therefore seem that improvement in the technical management of the case exerts little influence on the survival rate and that the most important factor in this connection is extent of the growth or the feasibility of complete extirpation of the lesion.

To summarize the operability and survival rate for all cases of carcinoma of the lung according to our present statistics, it may be stated that in a given group of 25 cases, only 15 would meet the criteria of operability and thus be explored, only 9 would prove resectable, almost 7 would survive the operation and only 2 would survive five years or longer (fig. 4). On the other hand, if it were assumed that all the patients were seen early enough that resection could have been performed in all 25 cases, then based on our present tatistics, which include many cases with palliative esection and consequently minimal chance of cure, 15 patients would survive six months to a year and 5 plus would survive five years or longer. There is no reason to consider this an impossible goal.

It is of interest to compare these results with those obtained in the treatment of gastric carcinoma. The relative frequency and the clinical importance of gastric cancer have been generally realized for a long time. There has been no comparable appreciation of the frequency and clinical importance of pulmonary cancer. Presumably, then, better results would be expected from treatment in gastric carcinoma than in bronchiogenic carcinoma, for the greater awareness of the problem should permit early diagnosis and therefore more effective therapy in a larger number of cases. Yet this is not the situation. The survival rate in carcinoma of the lung is now actually better than the survival rate in carcinoma of the stomach. The survival rate in carcinoma of the stomach is reported to be about 5 per cent, and our own experience is in accord with this figure. The survival rate in carcinoma of the lung is about 8 per cent. These observations seem to justify two conclusions: 1. The clinical course of bronchiogenic carcinoma is slower than that of gastric carcinoma. 2. With greater awareness of the problem of pulmonary cancer by the members of the medical profession, and with a consequent increase in the proportion of cases diagnosed early, there will be a considerable improvement in the survival rate of the disease.

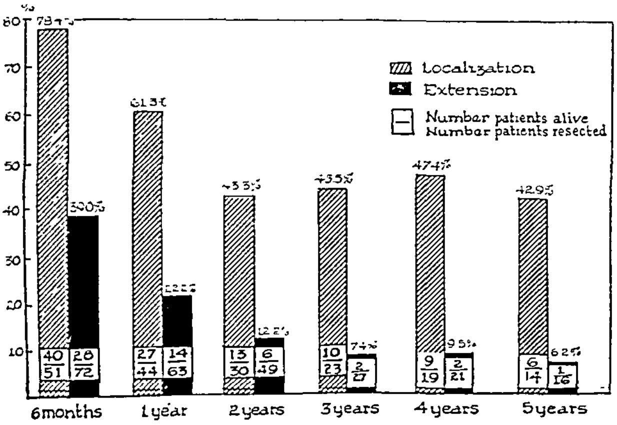

Fig. 3.—Survival rate after resection according to extension and localization of lesion.

SUMMARY AND CONCLUSION

1. An analysis has been made of the experience with primary pulmonary cancer during a period of almost twelve years and in a total of 412 cases, with special emphasis on diagnostic considerations and survival rates.

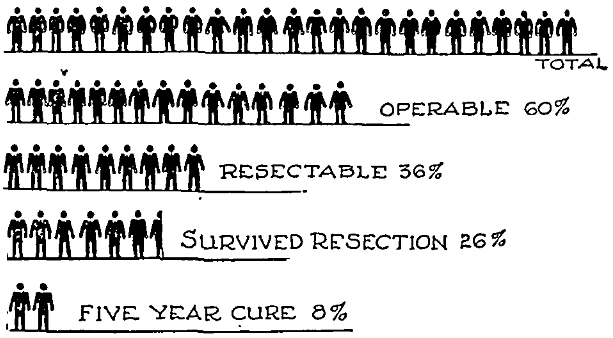

Fig. 4.—Schematic representation of actual survival expectancy in pulmonary cancer based on present experience.

2. Bronchiogenic carcinoma is a common lesion and probably represents about 10 per cent of all carcinomas. It is a disease primarily of men, most frequently in the fifth, sixth and seventh decades of life.

3. The right lung is involved somewhat more frequently than the left. In the present series of cases of resection, the upper lobes of both lungs and the lower lobe of the right lung were involved with equal frequency.

4. The disease begins insidiously, and there is no characteristic clinical picture. The most important factor in making an early diagnosis is the assumption that an unexplained thoracic disorder in a man past 40 years of age is bronchiogenic carcinoma until proved otherwise. Frequently the first manifestation in bronchiogenic carcinoma is an antecedent respiratory infection, the symptoms of which do not subside as they normally should.

5. Routine roentgenologic examination is the most valuable of all diagnostic methods. Bronchoscopic examination, when it permits visualization of the tumor and removal of tissue for biopsy, is perhaps the most accurate. Unfortunately, the lesion in a high proportion of cases (approximately half of the present series) is beyond the range of bronchoscopic visualization. Cytologic examination of the sputum or the material obtained by bronchoscopic aspiration is of increasing diagnostic importance.

6. Although it is extremely desirable to make a positive diagnosis before operation, in many instances (in the present series, 33 per cent) it is necessary to confirm the presumptive diagnosis by exploratory thoracotomy. The incidence of operability in carcinoma of the lung remains discouragingly low and emphasizes the need for wider recognition of the problem and for earlier diagnosis. Of the 412 cases in the present series, 246 (59.7 per cent) were explored and 147 (35.7 per cent) were resected. In simpler terms, of every 3 cases 2 will appear operable and 1 will prove resectable.

7. The surgical mortality has shown progressive improvement. Whereas the total mortality was 24.5 per cent for the entire series, it was 46.4 per cent for the group operated on before 1942 and 19.3 per cent for those operated on since that date.

8. The most frequent cause of death in the cases [illegible]le the patient was in the hospital was cardiovascular disease (47 per cent). This risk must be assumed if patients in whom cardiovascular complications are likely to develop are not to be denied their chance of salvage.

9. Of the patients in whom resection of the lung was possible and who were operated on five years ago or more, 23.3 per cent are still alive. This gives about an 8 per cent five year survival rate for all cases of carcinoma of the lung.

10. Although the results following the surgical treatment of primary malignant neoplasms of the lung are not good at the present time, they are better than those obtained in the treatment of gastric carcinoma, even though this latter lesion has been known for some time and its frequency is generally appreciated by the members of the medical profession. When the physician becomes cognizant of the relative frequency of primary pulmonary malignant neoplasms and recognizes these cases earlier, much better results will be obtained. The fact that a better than 20 per cent five year salvage rate can be obtained in cases of resection, in many of which only palliative resections are performed, indicates that the lesion is relatively slow-growing and that the ultimate outlook is not as pessimistic as it has been considered in the past.

AMERICAN RADIOLOGY

Its Contribution to the Diagnosis and Treatment of Disease

GEORGE W. HOLMES, M.D
Boston

Radiology is, comparatively speaking, a youth among the great medical specialties. Its entire life history lies within the life span of the average person; it is only half as old as the American Medical Association. Roentgen made his great discovery on Nov. 8, 1895. Radiology may be said to have appeared as a specialty in American medicine in the year 1900 with the organization of the American Roentgen Ray Society. It was not listed as a major specialty by the American Medical Association until 1921. Yet in this relatively short period of time it has revolutionized the practice of medicine. Physicians have always been prompt to utilize great scientific discoveries whenever they seemed to offer help in the diagnosis or treatment of disease. In the long history of medicine there is no record of the acceptance of a scientific discovery with such enthusiasm as that which greeted the roentgen ray. During the year 1896 more than one thousand articles and fifty books on the subject were published;[1] three of these books and many of the articles were on the use of the roentgen ray in medicine.

In the early years discoveries were being made almost daily and were being reported by surgeons, internists, general practitioners, engineers and physicists; and it is still a fact that many of the great advances in radiology are being made by workers outside the specialty. This is true to some extent in any new field, but radiology, perhaps more than any other specialty, is dependent on progress in other branches of medicine and on the instruments which it uses. Each step forward in associated fields has been followed by a corresponding advance in the science of radiology. It has rarely been the leader, but with an increase in the number of young *men well trained in the basic sciences who are entering* the specialty one may expect the radiologist to take a more active part in medical research. No other specialty with the exception of pathology, which is not a clinical specialty, covers as wide a field. Perhaps it is this very wideness of opportunity that has prevented detailed study, and without detailed study new facts *are not discovered. On the other hand, an amazing* number of advances in the diagnosis and treatment of disease, covering almost the entire field of medicine, may be directly attributed to the use of the roentgen ray. I shall point out only a few which seem to me to have had the greatest effect on medical progress.

CONTRIBUTIONS TO DIAGNOSIS

Diseases of the Bones and Joints.—The first use of the x-ray in medicine was in the diagnosis of diseases of, or injury to, the bones and joints, and this is still one of its most important uses. So many reports appeared almost simultaneously that it is impossible to give priority to any one author, but the names of some of the early workers have become permanently associated with certain procedures or with certain diseases. Warren's anatomic variations of the hands and feet, Hickey's[2] work on the development of the human skeleton, and Baetjer's contribution to the diagnosis of tumor of the bone are only a few of the first important publications. The great advances which have been made in the treatment of injuries of the bones and joints would not have been possible without the use of the roentgen ray. The painful manipulations formerly necessary to establish a diagnosis are no longer required. The data obtained from a properly conducted roentgenologic examination enable the surgeon to select at once the appropriate treatment, and repeated examinations demonstrate the results of treatment and the progress of healing. All this information is secured with the minimum amount of discomfort to the patient.

Although as early as 1896 records of disease conditions in bone began to appear in the literature, it was not until 1901 that any serious attempt to classify these lesions and to correlate them with the pathologic observations was made. Köhler[3] of Germany and Hickey, Caldwell[4] and Baetjer in this country made outstanding contributions, and later Baetjer and Waters[5] published their important work on tumor of the bone. This, with the investigations of Codman[6] and others, has brought the roentgen diagnosis of lesions of the bone to such a degree of accuracy that it is now considered the most valuable single factor in prepathologic diagnosis.

There are a considerable number of more or less generalized diseases of bone, perhaps best illustrated by hyperparathyroid disease, which have become better understood following the general use of the roentgen ray.

On the Board of Consultation and from the Department of Radiology, Massachusetts General Hospital.

Centennial address read before the Section on Radiology at the Ninety-Sixth Annual Session of the American Medical Association, Atlantic City, N. J., June 11, 1947.

Diseases of the Chest.—In 1901 Williams[7] of Boston published a book of 650 pages concerning the use of the roentgen rays in medicine and surgery. His studies of the chest were made almost entirely with the fluoroscope, yet so accurate and detailed were his observations that he was able to lay a foundation for the interpretation of most of the pathologic changes occurring in the chest. He was probably the first to describe the changes in the heart resulting from vitamin B_1 deficiency—the so-called beriberi heart, a condition unknown at that time. Williams was a diagnostician of unusual ability. He made a complete physical examination on all patients before subjecting them to examination with the roentgen ray, and many of his observations were checked by postmortem examination. He was one of the first to proclaim the importance of the roentgen examination in the diagnosis of diseases of the chest. With better equipment and increasing ability in the art of interpretation, Williams' statements have been amply justified. Most clinicians today would hesitate to make a negative diagnosis without the help of the roentgen ray.

The development of iodized oil by Sicard and Forestier[8] in 1921 and its use in visualization of the bronchial tree provided a new and dramatic approach to the diagnosis of diseases of the bronchi. It has added greatly to the understanding of such lesions as bronchiectasis and tumor of the bronchi. The recent advances in thoracic surgery and in the use of the bronchoscope have made it possible for the radiologist to interpret more accurately shadows such as those caused by obstruction of the bronchi, which formerly were not well understood.

The work of Hampton and Castleman[9] and others on the diagnosis of pulmonary infarction has led to the development of new therapeutic procedures in the management of pulmonary emboli.

Although the use of the roentgen ray has not been of as much assistance to the clinician in the study of the heart and great vessels as in the examination of the respiratory system, nevertheless it has led to a better understanding of the anatomic and physiologic structure of these organs. Among the early contributors in this field were Williams, Baetjer and Pfahler in this country and Köhler in Europe. In 1905 Köhler[10] introduced teleoroentgenography. This procedure—the taking of films at great distances—produced roentgenograms free from magnification and distortion which permitted accurate measurement of the heart and great vessels. Many errors in the older methods were found and corrected. Perhaps the most important single contribution in this field was that of Robb and Steinberg,[11] who in 1938 gave a 70 per cent solution of iodopyracet injection ("diodrast" N. N. R.) into the median basilic vein and followed it by taking a series of roentgenograms of the heart, great vessels and lungs. This method is of great value as a means of studying the physiology of these organs; it is also of assistance in studying the anatomy of the heart in both health and disease, as shown by Sussman and his associates.

The use of motion pictures to demonstrate the living, moving organs of the chest has been attempted by many workers. The observations made by Stewart[12] are perhaps the most important, as they have laid a foundation on which others, using equipment soon to be developed, may add a new chapter in roentgen diagnosis. Stewart, by photographing the image on the fluoroscopic screen, was able to demonstrate the pulsating heart after its chamber had been made opaque by the Robb-Steinberg method. With improvement in fluoroscopic screens and development of a method of intensifying images produced by light of low intensity, this procedure should become of considerable practical importance.

The Gastrointestinal Tract.—Probably the first successful attempt to use the roentgen ray in studying the gastrointestinal tract was made by Cannon[13] in 1898, when he introduced opaque substance into the esophagus of animals. In 1901, in collaboration with Williams, he studied the human stomach after the ingestion of a meal containing bismuth subnitrate But it was not until after the publications of Rieder[14] in 1904 that this method of examination became generally accepted. During the next decade the chief progress was along the lines of improvement in technic and in the correlation of abnormal observations. It was in this period that serious injuries to persons who had exposed themselves to the roentgen rays during prolonged fluoroscopic examinations appeared in considerable numbers, and the use of the fluoroscope began to be avoided by the radiologists in this country. As a result, most of the advances in gastrointestinal diagnosis were made in the clinics of Europe. In America the outstanding contributors were Leonard,[15] Cole,[16] and Carman.[17] Cole introduced a method of examination in which serial photographic plates replaced the fluoroscopic examination. Later, a modification of this method was combined with use of the fluoroscope to produce the present more or less standardized examination. Accurate diagnosis of lesions of the gastrointestinal tract has now become almost entirely dependent on the data obtained by a skilled observer during the roentgen examination. The early detection of lesions which in the past were not discovered until they had passed a curable state has led to advances in therapeutic measures and to the relief of many patients who would formerly have succumbed to their disease.

During the first years after Roentgen announced his discovery many attempts were made to demonstrate gallstones by the use of the roentgen ray. Beck[18] in 1900 was probably the first to achieve satisfactory results. With improvement in apparatus and in technic, Case,[19] Cole and George[20] and Leonard were able to demonstrate a high percentage of the gallstones of the opaque variety. It was not until 1924, however, when

Graham and Cole[21] showed that the intravenous injection of tetrabromphenolphthalein would cause the gallbladder to become visible, that the use of the roentgen ray in the diagnosis of diseases of this organ became firmly established. Since then many improvements in technical methods have been made, and new and better preparations for oral as well as intravenous administration have been introduced. Today, as a result, accurate diagnosis of the presence or absence of disease of the gallbladder can be made, and the physiology of the gallbladder both in health and disease is better understood than formerly.

The Genitourinary Tract.—That renal stones could be demonstrated roentgenologically was discovered almost at once, and this simple procedure has now reached such a degree of perfection that negative as well as positive observations are made routinely. The injection of opaque substances into the urinary tract in order to visualize the kidney pelves and ureters was done as early as 1904, and by 1918 the employment of a solution of sodium iodide for this purpose was producing satisfactory results. In 1923 Rowntree and his associates[22] conceived the idea that the urinary tract could be made visible by utilizing its excretory function. Their experiments were not entirely successful, but in 1928 Lichtwitz and others[23] produced an organic compound of iodine which, when injected intravenously, was excreted almost wholly by the kidneys. This procedure with some modifications has greatly simplified the methods of studying the urinary tract and, when combined with other measures, has removed most of its difficulties.

The roentgen method of examination has been widely used in the diagnosis of diseases of the reproductive organs, in both the male and the female, but in this field its use, though helpful, has not led to such far reaching results as in the examination of the urinary tract. Space does not permit a discussion of this subject.

Diseases of the Nervous System.—The roentgen examination played an unimportant part in the diagnosis of diseases of the nervous system until 1918, when Dandy[24] injected air directly into the ventricles of the brain through a trephine opening. A year later he described the procedure of encephalography using the intraspinal route.[25] This epoch-making accomplishment was followed by contributions from Sosman,[26] Dyke[27] and others, until the technical procedure and the diagnostic criteria were established, and the roentgen examination became an important factor in neurologic diagnosis.

In 1922 Sicard and Forestier[8] reported that iodized oil could be injected into the spinal canal for diagnostic purposes without injury to the patient and that in this manner tumors could be demonstrated. Subsequent work by Camp[28] and others placed the diagnosis of tumors of the spinal cord on a solid foundation. Mixter and Barr[29] as well as Hampton and Robinson[30] reported in 1934 that this form of examination could be used to show protrusion of intervertebral disks. The accurate diagnosis of this condition, in addition to the fact that it can be cured by surgical operation, has brought about a revolution in the diagnosis and treatment of low back pain.

Although many attempts have been made to show changes in the peripheral nerves, the results so far have been unsatisfactory.

It has been possible to sketch here only the briefest outline of the accomplishments of radiology in the field of diagnosis. Many important contributions have of necessity been omitted. For a more complete record the reader is referred to the publications of Brown[31] and Rigler.[32]

THERAPEUTIC USE OF THE ROENTGEN RAY AND RADIUM

The use of the roentgen ray in the treatment of disease was attempted as early as 1899, and since then it has been tried in a great variety of lesions. The results, although at times spectacular, have not brought about a revolution in therapeutic procedures as was the case in diagnostic methods. Perhaps the greatest usefulness of the roentgen ray, as of radium, is in the treatment of malignant tumors, especially those which do not respond well to other forms of therapy. In this field progress has been due largely to the efforts of the physicist, the engineer and the biologist, whose work has preceded that of the clinical radiologist. Improvement in equipment has been continuous. The establishment of an international unit of dosage by Duane and others permitted comparison of the results of treatment; and the work of Quimby[33] and others both in this country and in Europe has made possible a better understanding than formerly of tissue dosage and of the effect of irradiation on normal and abnormal cell growth. The biologist and the worker in medical research using radiation in some of its forms have been able to probe deeply into the mysteries of the living cell, the transmission of hereditary characteristics and the origin of life itself. The development of the cyclotron in 1941 by Lawrence and the production of radioactive isotopes have opened up an entirely new field of investigation. It is still too early to evaluate the studies being made on the movement of inorganic substances within the body or on the use of these substances in the treatment of disease. That the results will be of far reaching importance there can be no doubt.

CONTRIBUTIONS IN THE PREVENTION OF DISEASE AND IN PUBLIC HEALTH

Although the use of roentgenologic examination has made possible the detection of many types of disease in the early stages of their development, increasing the possibility of lasting cure, it has not been widely used in preventive medicine except in conditions involving the respiratory system. In the fight against tuberculosis the roentgen ray examination has played an important part. Williams in 1901 emphasized its value in this field, but it was not until Chadwick[34] in 1924 showed that it could be used to great advantage in the examination of school children that it became generally accepted in public health programs. The high cost of this type of examination prevented its adoption as a routine until 1938, when Potter,[35] two years after the development of the photofluorographic technic in Europe, introduced it into this country. This method has now been brought to a high degree of perfection, and its low cost permits its use in survey studies of large groups of persons. It has already added considerably to the knowledge of the prevalence of tuberculosis in different age groups and of the hazards to which the worker in various occupations is exposed.

RADIOLOGY IN MILITARY MEDICINE

The roentgen rays were first used as an aid in the diagnosis of war injuries by physicians of the British army during the Tirah Campaign of 1897.[36] The contributions of radiology, however, were of minor importance to military medicine until World War I, when roentgenography became widely used not only in the diagnosis of injuries and disease but also in the localization of foreign bodies and as an aid to their surgical removal. During the war large numbers of physicians became familiar with the possibilities of roentgen diagnosis in the hands of experts, and at its close there was great increase in the use of the radiologic examination ughout the United States. In World War II the of chemotherapy and the advances made in surgical nic reduced to a considerable extent the necessity for accurate localization of foreign bodies in the forward station hospitals. The principal value of the roentgen examination was in the large base hospitals and in the induction centers. The photofluorographic method made possible the roentgen examination of the chest in all candidates for induction into the armed forces, and as a result many persons unfit for military service were eliminated and a significant saving in health and money was accomplished. The data obtained from the examination of such large numbers of young men and women are also of considerable scientific value.

CONTRIBUTIONS TO MEDICAL EDUCATION

Teachers in the various branches of medicine began to use lantern slides made from roentgenologic plates to illustrate their lectures before 1900. That this method of presentation of material is of great value is shown by the rapidity with which it was accepted and by its almost universal use today not only in teaching but also in the presentation of scientific papers.

Organized teaching in radiology was of somewhat slower development. Its position as a medical specialty was questioned, and there was doubt in the minds of educators as to its importance in undergraduate teaching except when closely integrated with medicine in general. It was not until the need for graduate teaching in the specialties began to be recognized that the medical schools gave the teaching of radiology by a radiologist a place in their curriculums. The idea that undergraduate teaching should lay the foundation for the practice of medicine and that skill in the various specialties should be obtained by means of organized teaching and training after graduation has now been generally accepted. The establishment of an examining board in each medical specialty has done much to raise the standard of practice and has stimulated the growth of better graduate teaching. Radiology was among the first of the specialties to establish hospital residencies and to recognize the importance of a thorough knowledge of the basic sciences.

CONTRIBUTIONS TO ORGANIZED MEDICINE

The American Roentgen Ray Society was founded in 1900, the Radiological Society of North America in 1916, the American College of Radiology in 1923, the Section of Radiology of the American Medical Association in 1921 and the American Board of Radiology in 1934. In addition to the national organizations there are local organizations in nearly every state and in several of the large cities. The American Roentgen Ray Society and the Radiological Society of North America each publish a monthly journal of high quality, and the American College of Radiology has been a leader in the establishment of better relations between the hospital, the public and the medical profession.

Radiology like surgery is becoming a hospital specialty. The modern roentgen laboratory requires a considerable capital expense, and unless it can be used to capacity the cost per patient is beyond that which the average patient is able to pay. Furthermore, the number of nonambulatory patients is continually increasing. The answer to the problem seems to be either hospital or group practice. The examination and treatment of a large number of paying patients in a hospital clinic has created a situation in the hospital-physician relation which did not exist when the large hospitals were concerned only with patients unable to pay for medical services. Gradually, through the efforts of organized medicine, the conclusion has been reached that the interests of the patient are best served when medical fees are not divided between the physician and the hospital. In the working out of this problem and in its practical application, radiology has played an important part.

CONCLUSION

As one of the older radiologists, one who has seen radiology develop throughout the fifty years of its existence I cannot resist the temptation of making some predictions as to its future. Like surgery and other specialties requiring extensive laboratory facilities, its practice, even to a greater extent than at present, will be carried out in the hospital. Since progress in any field of human endeavor is dependent on the character and ability of the young men and women who choose it as their life work, radiologists must see to it that opportunity for interesting and remunerative work in their specialty is afforded. A wise and cooperative attitude on the part of the hospital administration and of the medical school can do much to assure the continuation of progress in radiology. The use of irradiation in the treatment of disease is becoming more limited and with the discovery of new methods for the treatment of cancer may become still more restricted. Advance in roentgen diagnosis, however, is as great as at any time in its history, and there is every indication that it will continue. Many problems are still unsolved, and the young physician entering this field should find an excellent opportunity for productive work.

HYPERTROPHIC PYLORIC STENOSIS

A Follow-Up Study

R. M. BENDIX, M.D.
and
H. NECHELES, M.D., Ph.D.
Chicago

The cause of hypertrophic pyloric stenosis is unknown. The number of theories about its cause, most of them vague and none accepted generally, attest to this. Our interest in the problem of the etiologic basis of this disease was aroused by seeing an adult with active peptic ulcer, who had undergone a Rammstedt operation as an infant. Since both hypertrophic pyloric stenosis and duodenal ulcer may be related to autonomic imbalance, the idea suggested itself that if we could analyze a number of similar cases, studying the patients as well as their families, we might learn about factors predisposing to this disease; in other words, if an autonomic imbalance exists in an infant with hypertrophic pyloric stenosis it may manifest itself later in life in one or another form.

Our data on patients and their families were obtained by direct contact with the patients or their physicians and by a questionnaire. A total of 20 histories were obtained. We consider that the information about these patients and their families warrants the following report.

Most subjects have been patients in our Children's Hospital (Sarah Morris) and had been operated on in our department of surgery. The surgical technic was the A. A. Strauss modification of the Rammstedt operation.[1] Three subjects not included in the tables are white male infants, 2 of whom died at the ages of 6 weeks and 10 months, respectively, and 1 of whom is living and well. They are mentioned here only for the percentage sex distribution of the disease and for data on family background. The data on the adult subjects are presented in table 1. Seventeen subjects are adults between 18 and 28 years of age, with an average age of 21¼ years. Four subjects are women (20 per cent) and 16 men (80 per cent). Two subjects are brothers, and 2 are female twins.

Two male subjects have active duodenal ulcer which have been sufficiently severe to require hospitalization and treatment for years in the free clinics (cases 1 and 2). Another male patient has typical ulcer syndrome without roentgenologic evidence of ulcer (case 3). This subject gives the impression of ulcer "constitution"; he is a highstrung, conscientious, hard-working, worrying, introverted young man, thin and underweight. A year ago he had a typical attack of grand mal. Patients 6 and 7 are twin sisters. Their weights at birth were 4 pounds 11 ounces (2,127 Gm.) and 4 pounds 3 ounces (1,900 Gm.), respectively, and both sisters are definitely underweight now. They are highstrung and have elevated basal metabolic rates. Patient 6 was unable to finish eighth grade in grammar school.

All adult patients comment on the fact that they suffered from no immediate or late effects of the Rammstedt operation. None of them, except those with ulcer symptoms in later life, ever suffered from upper abdominal distress. In the series of 17 adults only 4 (24 per cent, 1 woman and 3 men) described themselves as of stable nervous habitus (cases 14 to 17) and without complaint or disease. Of the 4, 3 are of normal weight and 1 is overweight; the brother of the latter (case 14) is of normal weight. Of the 17 adults, 7 are underweight, 8 are of normal weight and 2 are overweight. A summary of the medical histories of the adult subjects is presented in table 2.

TABLE 1.—*Follow-Up of Patients with Previous Rammstedt Operation*

Case; Sex	Present Age, Yrs.; Weight*	Present Condition	High-strung, Unstable, Irritable	Family Background
1 ♂	25 U	Duodenal ulcer	+	
2 ♂	21 U	Duodenal ulcer	+	Father and 1 brother have peptic ulcer
3 ♂	23 U	Ulcer syndrome, grand mal	+	Mother has migraine and hypertension
4 ♀	25 N	Migraine; constipated; cannot relax	+	Father had mental disease followed by Parkinson's disease; brother has migraine
5 ♂	20 N	Allergy	+	Father has migraine, allergy, spastic colon; mother has migraine and allergy
6† ♀	18 U	B. M. R. +14%	+	Father has migraine
7† ♀	18 U	B. M. R. +28%; very slow mentally	+	Father has migraine
8 ♂	28 U	Extremely low blood pressure	+	2 daughters with pyloric obstruction; father has mucous colitis; mother has migraine, nervous disease and constipation; father, mother and sibling have extremely low blood pressure
9 ♂	25 U	Constipated, with bleeding hemorrhoids; nervous skin disorder	+	Father, mother and sister constipated
10 ♂	23 O	Constipated, frequent gas pains	+	Mother died of tuberculosis
11 ♂	23 N	Blood in stools recently	+	Father and sister have ulcer syndrome; uncle has schizophrenia; grandfather had gallbladder disease
12 ♂	23 O	....	+	
13 ♂	18 N	....	+	Father and father's brother had penetrating ulcers, and each of them had a gastroenterostomy; father died from perforation and hemorrhage of ulcer; mother since childhood suffered from intolerance to starches and fats; had convulsions and fainting spells since the age of 10; she is in the hospital now with nontropical sprue
14‡ ♂	27 N	....	Stable	Father has spastic colon
15‡ ♂	21 O	....	Stable	Father has spastic colon
16 ♂	23 N	....	Stable	
17 ♀	21 N	....	Stable	

* N signifies normal weight; U, underweight, and O, overweight.
† Twins. ‡ Brothers.

The histories of the families of 10 of our subjects yield the following data. Subject 1, with active duodenal ulcer, reports that his father and one brother are suffering from chronic peptic ulcer. Patient 3, a medical intern, reports that his father and sister suffer from the ulcer syndrome. The father and uncle of patient 13 suffered from severe complicated ulcers. The mother and the maternal grandmother of one of the infants previously mentioned suffer from ulcer syndrome and from constipation.

Migraine is another disease well represented in this group. The following members are afflicted:

From the Departments of Gastro-Intestinal Research and Surgery of Michael Reese Hospital.

Aided by a grant from the A. B. Kuppenheimer Fund. The department is in part supported by the Michael Reese Research Foundation.

Dr. L. S. Reavley, Sterling, Ill., provided the data on patients 6 and 7; Drs. Jacob Meyer and A. Bernstein, Chicago, the data on patient 2. Dr. Isaac Abt gave information about many of the patients.

[1] Abt, I. A., and Strauss, A. A.: Clinical Study of Two Hundred and Twenty-One Operated Cases of Hypertrophic Congenital Pyloric Stenosis, M. Clin. North America 9: 1305, 1926.

mother of patient 3, a brother of patient 4, the father and mother of patient 5 (they have allergy in addition), the father of the female twins (cases 6 and 7) and the mother of patient 8. The mother of patient 13 is suffering from convulsions, intolerance to foods and. recently, from nontropical sprue.

Mucous or spastic colitis is present in the father of subjects 5, 8, 14 and 15. Of other symptoms related to *nervous mechanisms we may mention: extremely* low blood pressure of entire family (case 8), hypertension (case 3), mental disease of the father (case 4) and schizophrenia of the uncle (case 11). One male subject (case 8) 28 years of age had two daughters who had pyloric obstruction in their infancy; this may have been pylorospasm, since operation was not necessary.[2] A summary of the diseases in families of the adult subjects is presented in table 3.

COMMENT

We are dealing with a group of subjects selected for the occurrence of hypertrophic pyloric stenosis and the Rammstedt operation. Most of the adults are living now in different villages, cities and states and under widely varying economic and social situations. In this group it appears that the incidence of peptic ulcer and of ulcer syndrome (18 per cent), of body weight below normal (41 per cent) and of highstrung and unstable persons (77 per cent) is above the average incidence of such conditions in the members of the general population.

TABLE 2.—*Summary of the Medical Histories of the Adult Subjects*

Condition	Subjects	
	Number	Percentage
Peptic ulcer and ulcer syndrome	3	18
Normal weight	8	47
Underweight	7	41
Overweight	2	12
Stable	4	24
Irritable, highstrung, unstable	13	77
Thyroid deficiency	2	12
Allergy	1	6
Epilepsy	1	6

TABLE 3.—*Summary of Disease Incidence in the Families of Ten Subjects*

Disease	Incidence
Peptic ulcer or ulcer syndrome	8
Migraine	6
Allergy	2 or 3
Spastic colon	3
Pylorospasm	2

Since hypertrophic pyloric stenosis may be a disease which has its beginnings during embryonic life,[3] the data on the families of our subjects are of interest. These data are incomplete, since a number of the subjects do not know of the whereabouts or the condition of a number of close relatives. The diseases tabulated in table 3 are attributed by many to disorders in the autonomic nervous system. The incidence of these diseases in the families of our subjects and the multiple occurrence in one member of the family of a number of such disturbances seems to be high. It is possible therefore, that nervous disturbances in the parents play a role in the formation of the hypertrophic pylorus in the embryo or in the infant. A review of the pertinent references in the literature[4] reveals that most hypotheses on the etiologic basis of this disease center around nervous disturbances. The following theories have been assumed to prove that a disturbance in the autonomic nervous system plays a role in the causation of hypertrophic pyloric stenosis:

1. The disease is frequently seen in children who later show allergic tendencies.
2. The predilection of the disease for males suggests an origin in the sympathetic nervous system, because the male is more susceptible to peptic ulcer than the female.
3. There is a congenital lack of stability in the balance between gastric and pyloric contraction and relaxation; a disturbance in innervation of the stomach leads to contraction instead of relaxation when food reaches the antrum.
4. An abnormal arrangement of the neuromuscular mechanism of the pylorus leads to continuous activity and consequent hypertrophy of the sphincter.
5. Preexisting pylorospasm, due to abnormal reflex disturbances or local irritation, causes edema of the pyloric mucosa.
6. Hypofunction of the adrenal gland during the first few weeks of life causes vagotonia.

None of these theories have been proved, and no valid experimental production of hypertrophic pyloric stenosis has been reported. Results of experiments on rats have been interpreted as involving a vagus mechanism in hypertrophic pyloric stenosis.[3] Albino rats kept on a vitamin B deficient diet had litters of which 1.2 per cent exhibited an enlarged stomach and gastric retention. When the young animals were kept on a similar diet, 22 per cent of their offspring showed the same condition. The vagi of the sick animals showed myelin degeneration. In some of these rats there developed polyneuritis. These observations indicate that the animals did not have hypertrophic pyloric stenosis but were afflicted with beriberi. It has been reported that following the administration of dessicated yeast to pregnant women no case of hypertrophic pyloric stenosis was observed over a period of five years.[3] Against this stands the fact that hypertrophic pyloric stenosis does not spare the families of wealthy persons who have an ample diet rich in vitamins. Furthermore, we have been informed that hypertrophic pyloric stenosis does not occur in Filipinos, among whom beriberi is frequent, and that the only cases of hypertrophic pyloric stenosis observed in Manila were in white children or in children of mixed parentage.[5]

Aside from the theories quoted, there are a number of observations which may serve as a basis for further studies on the causative factors in hypertrophic pyloric stenosis:

1. It is an undisputed fact that the disease occurs predominantly in the male infant. This may indicate that hormonal disturbance exists in the mother (antepartum) or in the infant, which may *affect the autonomic nervous system.*
2. After the Rammstedt operation the pyloric tumor disappears; when a gastroenterostomy has been performed, or when a child with hypertrophic pyloric stenosis is not operated on, the tumor persists. We have been informed that in Copenhagen, Denmark, the Rammstedt operation is not performed. Infants with hypertrophic pyloric stenosis are treated with atropine in rather large doses; they are given a semisolid diet with careful feeding and nursing care. No deaths have been

---

[2] A case of a perforated, bleeding duodenal ulcer in an infant and of hypertrophic pyloric stenosis in another infant of the same family has been reported by Bird, C. E.; Limper, M. S., and Mayer, J. M.: Surgery in Peptic Ulceration of Stomach and Duodenum in Infants and Children, Ann. Surg. **114:** 526, 1941.

[5] Quintos, F. X.: Oral communication to the author.

recorded with this form of treatment, and complete recovery and normal growth of the patients has ensued.[6]

3. We have observed a seemingly high incidence of disturbances in adults on whom a Rammstedt operation was performed in their infancy and in the next of kin of these adults. Not infrequently there is a familial incidence of the disease.

The foregoing observations evidently do not answer the question of the origin of hypertrophic pyloric stenosis, but they may be helpful in the approach to a solution of the problem.

We do not believe that the Rammstedt operation involves a complete denervation of the pyloric sphincter. The nature of the operative procedure and the innervation of the sphincter make a complete denervation hardly plausible. However, the splitting of the circular muscle of the sphincter leads to a regression of the tumor. Abt and Strauss[1] and Ladd and Gross[4a] have commented on the fact that complete splitting of the muscle insured better results, particularly less postoperative vomiting, than incomplete splitting. The sectioned circular musculature seems to lose its power for concentric contraction and seems to undergo atrophy of disuse.

Our own observations point in the direction of autonomic and nervous lability in our patients and in their next of kin. Such symptoms as peptic ulcer and ulcer syndrome, nervous instability, migraine and spastic colon are considered by many to be due wholly or in part to disturbances in the autonomic nervous system. We are unable to offer statistical comparison with a normal segment of the population, but the incidence of these symptoms and diseases in both the patients and their families seems unduly high.

Why, then, is there a localization of a nervous imbalance in one organ, the pyloric muscle? A tentative hypothesis may be offered from the considerations already raised. A disturbance may localize and become more serious in an imbalanced organism than in a balanced organism, when a local irritating process is present. The embryo swallows meconium, cell detritus and possibly hair, with amniotic fluid. One or the other of these substances may so irritate the sphincter that edema, spasm and consequent enlargement result. It has been shown in this laboratory that meconium is a rather irritating substance.[7] However, it is an open question why this process should occur in the male predominantly, unless it can be shown that the male infant is more prone to have an autonomic imbalance that is the female infant.

SUMMARY

A follow-up study was conducted on persons who had undergone the Rammstedt operation for hypertrophic pyloric stenosis in their infancy. The families of a number of these persons also were investigated.

The age of the persons who had had a Rammstedt operation varied between 18 and 28 years, with an average age of 21¼ years. One pair of female twins and 2 brothers were in this series. The incidence of disturbances, mainly nervous ones, was high in both the group of patients who had had the Rammstedt operation and the group of close relatives of these patients.

A tentative theory is submitted, that hypertrophic pyloric stenosis is due to an autonomic imbalance plus a local irritation during embryonic life.

I. INTRODUCTION

Five patients having keratitis probably pathognomonic of lymphogranuloma[*] venereum are herewith reported. The appearance of the corneal lesions was identical in each patient. The lesions were also the same as that reported by Meyer and Reber[1] in 1940 in 1 patient, who was observed by one of us (H. G. S.) at that time. Ocular involvement is one of many manifestations of lymphogranuloma venereum, which is a widespread systemic disease. Inguinal involvement has been recognized for over a century, but it was not until the work of Durand, Nicolas and Favre[2] in 1913 that the disease was established as a specific entity. Knowledge of the complex nature of the disease and the numerous lesions produced by it awaited discovery of the Frei test[3] (1925) and the means of isolating the specific virus by Hellerström and Wassén[4] (1930).

II. INCIDENCE OF LYMPHOGRANULOMA VENEREUM

The distribution of lymphogranuloma venereum is worldwide; it is especially prevalent in the tropics. Three hundred patients were seen at the 20th General Hospital during the first twenty-eight months of its assignment in India. Koteen[5] quoted statistics from outpatient clinics of large hospitals as revealing that 20 to 40 per cent of Negroes and 2 to 5 per cent of white patients are or at one time have been infected.

III. GENERAL CLINICAL PICTURE

The clinical picture of lymphogranuloma venereum manifests itself in many ways. The primary involvement consists of a transient herpetiform or ulcerative lesion on the genitalia which appears after an incubation period of only a few days. This usually escapes notice. Invasion of the inguinal lymph nodes draining the area of inoculation usually occurs within ten to thirty days after infection. Inguinal lymphadenitis is therefore commonly the first manifestation of the disease. Constitutional symptoms, consisting of malaise, headache, fever and other grip-like signs, may be observed concurrently. The lymph nodes usually suppurate and form buboes. Involvement of other organs may occur at this time or only after a latent period

of months to years. Many different lesions have been reported associated with lymphogranuloma venereum, but evidence in support of such diagnoses has varied greatly. Koteen therefore classified the lesions said to be due to lymphogranuloma venereum into three groups:

- A. Lesions from which the virus has been recovered
  1. Primary genital lesions
  2. Inguinal buboes
  3. Esthiomene
  4. Urethritis
  5. Cervicitis
  6. Anorectal syndrome
  7. Conjunctivitis
  8. Meningitis
- B. Lesions from which the virus has not been recovered, but in which the supporting evidence is good
  1. Ulcerative colitis
  2. Salpingitis and parametritis
  3. Dermatologic manifestations
  4. Joint and bone infections
  5. Cervical and axillary adenitis
  6. Tongue and lip "chancres"
- C. Those in which the supporting evidence is only circumstantial
  1. Pharyngitis and tonsillitis
  2. Enteritis
  3. Ocular lesions other than conjunctivitis

IV. LABORATORY

The clinical signs of lymphogranuloma venereum can be supported by various laboratory tests which offer confirmatory or even final proof of the diagnosis.

A. Frei Test.—The Frei test, in which a reaction is elicited by injecting lymphogranuloma venereum antigen intradermally, is the most commonly used. The antigen is prepared from tissue infected by the lymphogranuloma virus and contains the inactivated virus itself. Once the patient has had lymphogranuloma venereum and Frei reaction has become positive, it probably remains so. False positive reactions are parently rare. Koteen stated that a repeatedly negative Frei reaction in a patient suspected of having lymphogranuloma venereum is reasonably strong evidence of the absence of this disease, except in those few patients who exhibit anergy. On the other hand, a positive reaction to the Frei test only implies that the patient has at some time been infected with the virus.

B. Complement Fixation Test.—The complement fixation test is helpful, though numerous cross reactions can occur, among which are psittacosis, syphilis, trachoma, atypical pneumonia, inclusion blennorrhea and other diseases. Levine and his associates [6] felt that since so many cross reactions could be demonstrated this procedure must be corroborated by a positive Frei reaction before the diagnosis of lymphogranuloma could be made.

C. Biopsy.—Biopsy of the lesion may reveal intracellular inclusion bodies which are suggestive of the diagnosis.

D. Recovery of the Specific Virus.—Final proof of the diagnosis is afforded by isolation of the causative agent, which can be done by injecting material from the suspected lesion into the brain of a mouse. A characteristic meningoencephalitis results. Extracts of this mouse brain, when properly treated and injected intradermally, elicit a positive Frei reaction in patients known to react positively to this test.

E. Miscellaneous Laboratory Tests.—Other laboratory findings may lend supportive evidence: 1. The white blood cell count is usually elevated, being 10,000 to 20,000. 2. The serum proteins may be elevated with increase in the globulin fraction. The level usually exceeds 8.0 Gm. per hundred cubic centimeters. 3. The sedimentation rate is commonly elevated. 4. The formaldehyde-gel test frequently elicits a positive reaction.

V. OCULAR LESIONS ASSOCIATED WITH LYMPHOGRANULOMA VENEREUM

Various ocular lesions, proved and unproved, have been reported in association with lymphogranuloma venereum. These have been well summarized by Macnie [7] and are therefore only tabulated. The ocular lesions only presumptively due to lymphogranuloma venereum (table 1) include keratoconjunctivitis, conjunctivitis, uveitis, episcleritis, peripapillary edema and flame-shaped retinal hemorrhages. The patients with proved ocular lesions from which the virus has been recovered (table 2) were 6 in number. Five of these patients had Parinaud's syndrome. The other, whose keratoconjunctivitis was reported by Oliphant and his co-workers,[8] was of particular interest in view of the observations reported herein. This patient had bulbar conjunctival injection which was followed in twelve days with a keratitis beginning as a small marginal corneal ulcer within the limbus at 12 o'clock. A few keratic precipitates were present. Experimental induction of ocular lesions has been carried out by several workers (table 3). Satani and Sano [9] (1936) and Macnie [7] (1941) inoculated the virus into the anterior chambers of rabbits and guinea pigs, producing keratitis, conjunctivitis and iritis. Inclusion bodies were noted in the tissues and studied pathologically. Levaditi [10] and co-workers reproduced Parinaud's syndrome in the chimpanzee in 1935. Conjunctivitis has been noted to occur in experimental animals following the intracerebral inoculation of the lymphogranuloma virus.

VI. REPORT OF CASES

We are reporting herein 5 patients having a type of keratitis which seems pathognomonic of lymphogranuloma venereum. In all the patients about to be discussed, the diagnosis of lymphogranuloma venereum was first suggested by the characteristics of the ocular lesion.

Case 1.—A 25 year old Chinese soldier was admitted to the 20th General Hospital on March 9, 1943 because of a hydrocele involving the left testicle. On March 12 a hydrocelectomy was performed with the patient under spinal anesthesia. On April 8 the left eye became inflamed. The severity increased, necessitating an ophthalmologic consultation on April 17. At that time examination revealed definite circumcorneal injection. A corneal infiltrate was present within the upper limbus, involving the upper third of the cornea. A massive fleshy superficial vascularization which elevated the surface of the cornea was seen extending 1.5 mm. into the cornea from the upper limbus. The appearance suggested an epaulet. Punctate staining areas were seen over the infiltrated portion of the cornea in advance of the vascularization. The cornea was thickened, particularly near the limbus, where the infiltrate involved its entire thickness. The left pupil was smaller than the right. Cells in the aqueous and an aqueous flare were present. Recalling to mind the previous case reported by Meyer and Reber of a patient with almost identical abnormalities, a tentative diagnosis of keratitis due to lymphogranuloma venereum was made. Inquiry revealed a history of buboes two years previously. Scars were seen in the right inguinal region. A Frei test elicited a positive reaction. An attempt was made to find other possible etiologic agents. Conjunctival scrapings were negative for inclusion bodies of trachoma. Cultures of the eye revealed no pathogenic organism. His Kahn reaction was negative. Routine blood cell counts were normal. No infected teeth were found. He was first given atropine 1 per cent twice daily, hot compresses and sodium sulfathiazole 2 per cent to use locally every hour. This was continued with slight improvement until April 23. He was then given sulfadiazine orally, 1 Gm. every six hours. Improvement was subsequently rapid, and his eye became quiet, permitting him

to be discharged from the hospital three weeks later. Only a small opacity remained at the upper limbus.

Case 2.—A 32 year old Negro soldier was admitted to the outpatient department of the 20th General Hospital on June 25, 1943. He had mild conjunctival injection, but no corneal involvement could be noted. During the next three days his eye became progressively inflamed and mild ciliary flush developed. An infiltrate appeared within the upper limbus. Punctate areas within the upper limbus stained with fluorescein over the infiltrated area. He was therefore admitted to the hospital as a ward patient on June 28. The ocular condition became more severe. The injection increased and the infiltrate became more pronounced, involving the entire corneal thickness at the limbus. The involved cornea was thickened. Within ten days superficial vascularization began to appear within the upper limbus, which shortly became salmon colored or fleshy in appearance and was again elevated, resembling an epaulet (fig. 1). All routine etiologic studies including exclusion of foci of infection were negative in result. At this time, the appearance of the corneal lesion again suggested the diagnosis of lymphogranuloma venereum. Investigation revealed scars of buboes from which he had suffered three years previously. Trachoma was again excluded. Two different Frei tests elicited positive reactions, so that a presumptive diagnosis of keratitis due to lymphogranuloma venereum was made. Sulfadiazine was then administered, 1 Gm. every four hours. Atropine and hot compresses, which he had been receiving, were continued. Complete recovery resulted during the next three weeks with no visual loss.

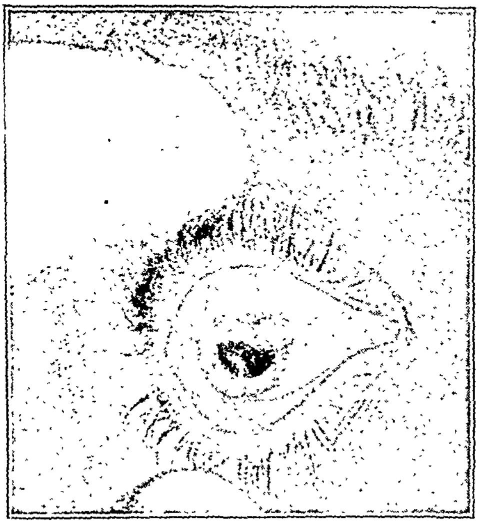

Fig. 1.—Keratitis associated with lymphogranuloma venereum (case 2).

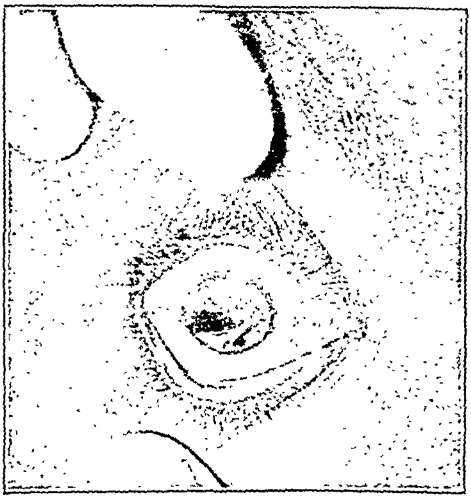

Fig. 2.—Keratitis associated with lymphogranuloma venereum (case 3).

Case 3.—On March 10, 1945, a 21 year old Negro soldier was admitted to the 20th General Hospital, where he was placed under the care of the venereal disease section. He gave a history of exposure during November to a native prostitute in Calcutta. A primary lesion had never been noted, but he was admitted to the 70th Field Hospital on Jan. 26, 1945 because of swelling in his right groin. He was given inadequate doses of sulfathiazole for eight days with some regression of the swelling. About the middle of February, or three weeks prior to admission to the 20th General Hospital, he experienced discomfort in his right eye with considerable inflammation and redness. On admission to the section on venereal disease of the 20th General Hospital on March 10, in addition to the inflamed eye, he was found to have swollen, tender, matted inguinal lymph nodes on the right side. He had some scars over his back and chest, suggesting a possible macular eruption due to syphilis. The diagnosis of secondary syphilis was considered the most likely possibility. Ophthalmologic consultation was requested, and examination revealed moderate conjunctival injection with superimposed ciliary flush involving the right eye. From 9:30 to 3 o'clock there was an area of corneal opacity (fig. 2). This ran in an arc within the limbus, extending 4 mm. into the cornea at its center. The infiltrate involved the entire thickness of the cornea peripherally, but gradually became superficial centrally. A profuse superficial vascularization extended from the limbus to within 1.5 mm. of the advancing border of the infiltrate. As in the other cases, vascularization was profuse and elevated the surface of the cornea, suggesting an epaulet. Multiple punctate staining areas could be seen in advance of the vascularized portion. A few scattered macular and nebular opacities were seen still further centrally in the cornea, all being superficial. A faint aqueous flare with a moderate number of floaters was seen. The fundi were normal. The diagnosis of keratitis due to lymphogranuloma venereum was immediately suggested. Subsequent studies revealed no other causes for the keratitis. Serologic reactions of his blood were negative. Repeated Frei tests elicited positive reactions. The serum proteins were within normal limits and the albumin-globulin ratio was normal. On March 13 he was started on sulfathiazole, 1 Gm. four times daily by mouth. Response to treatment was poor. The lesion was only converted from acute keratitis into a more indolent chronic affair.

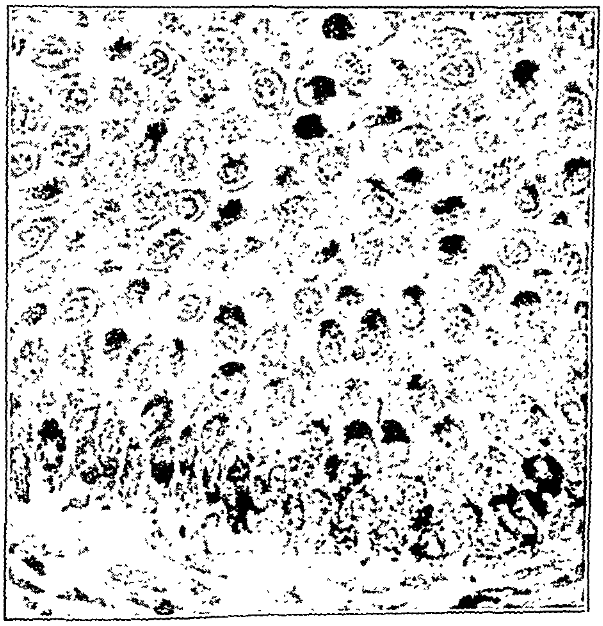

Fig. 3.—Photomicrograph demonstrating intracellular inclusion bodies (case 4).

On April 12 a similar infiltrate began to develop within the lower limbus. Administration of sulfathiazole was continued for nine weeks with little effect. He was then given three weeks of intramuscular penicillin therapy, also without benefit. At this point the patient was transferred back to the zone of the interior and could no longer be followed. Visual loss from corneal opacity was almost a certainty.

Case 4.—A 26 year old Negro woman came to the ophthalmology outpatient department of the Hospital of the University of Pennsylvania on April 3, 1945. She complained of a painful left eye of about three months' duration. Vision of the right eye was 6/6 and of the left eye 6/12 The right eye showed no abnormalities. The conjunctiva of the left eye was injected. In the region of the upper limbus a fleshy, vascular growth was seen extending onto the cornea It had the appearance of an epaulet overriding the limbus and involved the upper two fifths of the cornea. The cornea was infiltrated and showed punctate staining with fluorescein in advance of the vascularized area. No flare or floaters were seen, but several small pigmented keratic precipitates were present. The patient was admitted to the ward for study. Culture from the conjunctiva revealed no growth. No cause could be found by routine studies, including search for foci, tuberculin and brucellergin tests, roentgen studies and various consultations. At this time a diagnosis was not made. Neoplasm was considered. She was followed as an outpatient for a month, during which time the eye gradually became worse. The limbal growth further invaded the cornea, and several superficial corneal infiltrates developed within the lower limbus. At this time, May 7, the resemblance to the previously observed cases was noted and lymphogranuloma venereum was supected. Accordingly, a Frei test was done, and the reaction was found to be strongly positive. No other stigmas of lymphogranuloma venereum were found. She was given sulfadiazine to take by mouth as an outpatient. She then disappeared for three months. When she was induced to return for follow-up, on August 20, she stated that after she had taken the sulfadiazine for a short time the eye became so much better that she did not bother to report for follow-up. By this time the corneal infiltrate had increased within both the upper and the lower limbus, so that there was only a small irregular horizontal clear area at the center of the cornea. However, the injection was less and the vascularized tissues overriding the limbus above had flattened out. The lesion at the lower limbus now showed epaulet-like vascularization and an identical appearance to the cornea within the upper limbus. The patient refused further treatment and did not attend the clinic for six months, at the end of which time the eye had again become uncomfortable. The corneal opacification had increased, the eye showed a ciliary flush and an aqueous flare was present. She consented to readmission to the hospital on Feb. 21, 1946 for further treatment. Her Frei reaction was again strongly positive. Her sedimentation rate was moderately increased. She had hyperproteinemia, the value being 8.2, with an albumin-globulin ratio of 4.7 to 3.5. During this admission a biopsy of the corneal lesion at the upper limbus was taken for microscopic examination and mouse brain inoculations. She requested release from the hospital after two weeks because of difficulties at home. She was therefore again given sulfadiazine to take orally at home. After leaving the hospital her eye again became considerably worse until she was finally readmitted, on March 21. Her vision in the affected eye had been reduced to counting fingers because of infiltrate and vascularization throughout the cornea. She was immediately given sulfadiazine combined with fever therapy in the form of typhoid vaccine intravenously. After three weeks on this regimen the cornea no longer stained with fluorescein and the eye was whiter. Improvement continued and the eye became entirely quiet during the following three weeks. She was last seen on April 23, 1947. The eye was quiet. Numerous corneal maculas were seen which were mostly superficial but which kept her vision at 6/60. Remnants of superficial and deep vessels were seen in the cornea within the limbus above and below, signifying that deep as well as superficial vascularization occurred when the keratitis was active. Although they were not seen while the keratitis was active, the finding of deep ghost vessels was not surprising, since all layers of the cornea are involved by the keratitis.

Microscopic study and virus inoculation experiments were carried out by one of us (W. H.). Pathologic study revealed many cytoplasmic inclusion bodies in the epithelial cells of the section (fig. 3). This consisted of aggregations of small round bodies, 200 to 300 microns in diameter, which stained dark purple with Giemsa stain. In many places individual particles or small groups of these particles were found. They probably represent the elementary bodies of the lymphogranuloma virus as first fully described by Miyagawa,[11] who called them granulocorpuscles. Serologic studies using the patient's serum were also performed. A complement fixation test with chick embryo antigen ("lygranum") elicited a positive reaction in a very high dilution, giving a serum antibody titer of 1 to 256. The antigen used was the same material which was employed for the Frei test. Extensive studies have been carried out in an attempt to isolate the causative agent. Intracerebral injection into white mice was the first step. In the first mice no lesions developed. On the twelfth day they were killed, their brains emulsified and injected into new mice. Again no lesions developed, so that this line of approach was discontinued. A second attempt was made on chick embryo. Material remaining from the biopsy which had been kept at — 10 C. was injected into the yolk sac of 8 day old chick embryos. They survived eight days of further incubation and were harvested. A 20 per cent suspension was passed to new eggs and also to white mice by the intracerebral route. These mice showed some signs of cerebral lesions on the fourth and fifth days. They lost weight and on suspension by their tails exhibited tremor. When released, they had difficulty in regaining equilibrium. Passage of the brains from these mice to other mice produced severe lesions and death. At first it was felt that we were dealing with a virus of the lymphogranuloma venereum group, but further studies have shown that it undoubtedly was a contaminant.

Case 5.[12]—A 31 year old Negro soldier was admitted to Valley Forge General Hospital on April 10, 1947 because of inflammation of his right eye of four weeks' duration. He had received no treatment during this time. His vision was 20/100 in the right eye and 20/30 in the left. This could be improved to 20/30 in the right eye with a pinhole disk. External examination of his right eye revealed slight edema of the upper lid. A mild ciliary flush was present. Areas of keratitis, rather heavily vascularized superficially, could be seen within the upper and lower limbus. External examination of the left eye revealed no abnormality. With the slit lamp an area of corneal infiltrate involving the entire thickness of the cornea was seen within the upper limbus from 10 to 2 o'clock above and from 4 to 8 o'clock below. These extended into the cornea about 2.5 mm. Some of the infiltrated area within the lower limbus stained in a punctate manner with fluorescein. The cornea was slightly thickened over the involved areas. Dense vascularization extended from the limbus into infiltrated portions of the cornea for about 1.5 mm. A few cells and a faint aqueous flare were seen. In the left eye a nebulous opacity involving all layers of the cornea could be seen within the upper and lower limbus in distribution corresponding to the areas of keratitis in the other eye. Within these areas, ghost vessels could be seen at all depths. The aqueous was clear. Ophthalmoscopic examination revealed normal fundi. The intraocular tension was normal. Various routine studies for the possible causation of the keratitis were carried out. Cultures by scraping of the areas of keratitis within the lower limbus revealed no growth. Conjunctival cultures enabled recovery of hemolytic Staphylococcus aureus organisms which

11. Miyagawa, Y., and others: Studies on the Virus of Lymphogranuloma Inguinale Nicolas, Favre and Durand, Jap. J. Exper. Med. 13: 1, 331, 723 and 733, 1935.

12. We were enabled to see this patient by Jack H. Bristow, Major, Medical Corps, Chief 1st Eye, Ear, Nose and Throat Section, and Paul Lambrecht, Captain, Medical Corps, Assistant Chief, Valley Forge General Hospital.

were coagulase negative. Brucellosis agglutination reactions were negative. A tuberculin test elicited a positive reaction to 0.001 mg. Other routine studies were negative in result. During the week of May 5 the patient was seen in consultation by P. Robb MacDonald, M.D., who suggested the diagnosis of lymphogranuloma venereum on the clinical appearance of the lesion in the right eye. The vascularization, however, was not so heavy as seen in some of the cases and the appearance was that of a subsiding lesion. One of us (H. G. S.) saw the patient the following day and agreed with this impression. The opinion was also expressed that the scarring and old vascularization, some of which involved the deeper layers of the cornea of the left eye, were probably due to a similar type of keratitis involving this eye. Inquiry revealed a history of buboes involving the left inguinal region in 1933. The patient also stated that he had had an inflamed left eye during May, June and July, 1941. No diagnosis was made at the time, although he had been treated in a civilian hospital eye clinic. Because of this tentative diagnosis of lymphogranuloma venereum, a Frei test was done and found to result in a strongly positive reaction on April 25 and again on May 26. A complement fixation test elicited a negative reaction. The patient had been receiving 5 per cent sulfathiazole ointment locally every two hours and atropine 3 per cent since April 22. The eye was rapidly improving and continued to do so until May 10, when all treatment was stopped. By May 30 the eye was entirely quiet and the infiltrate as well as the vascularization was clearing.

VII. COMMENT

The 5 patients described in this paper had identical corneal lesions. The involvement began within the upper limbus in every instance. The lesion was observed in 5 patients but was followed from its onset in only 1, in whom it began as an ordinary keratoconjunctivitis localized to the region of the upper limbus. Corneal infiltrates appeared within the upper limbus, some of which stained with fluorescein. As the number of infiltrates increased they became confluent, forming an arc of infiltrate within the upper limbus involving one third to one half of the circumference of the cornea. Scattered infiltrates kept appearing just ahead of the area of keratitis as it advanced into the cornea. The entire thickness of the cornea became involved by the infiltrate at the limbus, but the process gradually became superficial centrally over its advancing border. The cornea was thickened over the involved area. A dense superficial vascularization from the limbus covered the infiltrate peripherally, with all of the vessels ending abruptly well within the advancing border of the infiltrate. The vascularization was characteristically so profuse that it elevated the surface of the cornea, somewhat resembling an epaulet. All our patients presented identical abnormalities. The corneal lesion was accompanied by a mild to a moderate iridocyclitis in all cases. An occasional keratic precipitate occurred. In 2 of the patients, as the disease ran its course, a similar infiltrate and vascularization appeared wthin the lower limbus. Another of the patients had active involvement within the upper and lower limbus when first seen and scars probably due to a similar lesion within the upper and lower limbus of the other eye. As the keratitis subsided, ghost vessels could be seen at all depths of the cornea, showing that vessels had probably come in at corresponding levels during the active stage of the infection. This finding would be expected in view of the infiltrate through all the layers of the cornea.

Definite proof that the corneal lesions were caused by the lymphogranuloma venereum virus could not be obtained, but the supportive evidence was fairly substantial. 1. The corneal lesions were identical in appearance in each patient. 2. The appearance of the corneal lesion was so characteristic that, the patient of Reber and Meyer having been seen in 1940, the diagnosis of lymphogranuloma venereum was suggested by the ocular lesion in each of the subsequent cases. 3. Confirmatory diagnostic evidence of lymphogranuloma venereum was obtained from additional clinical and laboratory studies. (*a*) All of the patients herein reported had positive Frei reactions. (*b*) Four of the patients had evidence of involvement of inguinal lymph nodes, manifest in 3 of the patients by scars of healed buboes and in the other by active lymphadenitis. (*c*) One patient (case 4) showed, in addition to a positive Frei reaction, a strongly positive complement fixation reaction. Biopsy of the corneal lesion revealed changes compatible with those of lymphogranuloma venereum. 4. This characteristic corneal lesion has, in our experience, never been seen in patients without corroborative tests of lymphogranuloma venereum.

Definite proof of the etiologic diagnosis, however, must await isolation of the causative agent. Unsuccessful attempts were made to recover the virus from the corneal lesion of our fourth patient. The large number of elementary bodies visible in the microscopic section of our biopsy implied that the virus should have been isolated with ease. On the other hand, the strongly positive complement fixation reaction indicated a high antibody level in the serum. This could have resulted in inactivation of the organism during the process of releasing the virus from the infected tissue cells. During this process, the tissues must be emulsified by grinding in a mortar with an abrasive, at which time it is impossible to avoid contact of the virus with the antibody.

The differential diagnosis includes marginal keratitis, trachoma and Mooren's ulcer. Marginal keratitis can be excluded by bacteriologic studies and by the appearance of the lesion associated with lymphogranuloma venereum keratitis, which involves the entire thickness of the cornea, is continuous with the limbus and shows an epaulet-like vascularization. Trachoma causes a bilateral lesion with much less dense vascularization of the cornea. It also produces conjunctival changes which are diagnostic. Mooren's ulcer usually occurs in older patients, is indolent and has an undermined advancing border.

Though none of the eyes in our patients was lost, the prognosis for vision is serious. One of the 5 eyes suffered marked loss of visual acuity, and it was reasonably certain that another would have permanent visual impairment, although follow-up was impossible. That the disease can be prolonged was demonstrated by our fourth patient.

VIII. TREATMENT

The treatment of keratitis associated with lymphogranuloma venereum should be that prescribed for the systemic disease. This treatment was outlined by the War Department in War Department Technical Bulletin TB Med. 157.[13] This consists of the administration of sulfadiazine orally in full therapeutic doses for a period of twenty-one days. Only 2 of our patients responded poorly to sulfonamide therapy. These had had inadequate doses or abbreviated courses of sulfonamide drugs prior to being seen by us. This would suggest either that the lymphogranuloma venereum virus had become sulfonamide fast or that this strain of virus was particularly resistant to this form of chemotherapy.

[13] Chancroid, Lymphogranuloma Venereum, and Granuloma Inguinale, United States War Department Technical Bulletin (TB Med 157), Washington, D. C., Government Printing Office, April 1945.

IX. SUMMARY

A type of keratitis, identical in appearance, is reported in 5 patients with other evidence of lymphogranuloma venereum. Evidence supporting the diagnosis of lymphogranuloma venereum was: (*a*) A positive Frei reaction in all the patients; (*b*) involvement of inguinal lymph nodes, active in 1 patient and healed in 3; (*c*) a strongly positive complement fixation reaction in 1 patient, and (*d*) in the corneal lesion of the same patient inclusion bodies compatible with lymphogranuloma venereum shown by biopsy. Although the prognosis is serious, treatment with sulfathiazole or sulfadiazine should be carried out in full therapeutic doses for not less than three weeks.

ABSTRACT OF DISCUSSION

Dr. John P. Macnie, New York: The authors describe a keratitis of distinctive characteristics and present evidence of its association with lymphogranuloma venereum. This disease is caused by a virus which is larger than the true viruses and is a member of a group of similar viruses, in which group are included those causing psittacosis, trachoma and inclusion blennorrhea, as well as lymphogranuloma venereum. It is interesting that in this group are two diseases of the eye. Lymphogranuloma venereum is a true venereal disease, but instances of direct ocular infection as in laboratory workers have been reported. Evidence has been offered that it is at times a generalized infection, the virus having been recovered from the spinal fluid and blood of an infected person. In the laboratory the virus has been recovered from the fetuses of pregnant mice that have been inoculated with the disease. The mechanism of involvement of the corneal tissue is not clear. It would seem to be a direct infection of the tissues with the virus from the evidence presented in the last case reported in this paper. There may be three methods of eye involvement: direct infection with the virus, a local toxic effect in the eye as a result of the genital lesion, or an allergic manifestation. Lymphogranuloma venereum is not an uncommon disease, but ocular lesions associated with it have been reported comparatively rarely. It would appear that such a distinctive picture as that described in the paper would have been recognized if it were common. The eyes of patients in whom a diagnosis of lymphogranuloma venereum had been made at the Vanderbilt Clinic in New York were examined over an interval of several months. The anterior segments of the eyes were studied with the corneal microscope. In none of these patients was any evidence of preexisting or active corneal inflammation identified. The characteristic corneal involvement described in this paper seems to be an uncommon complication of lymphogranuloma venereum, and I wonder whether the authors have reached any conclusion as to its incidence. The authors of this paper are to be complimented for calling attention to a definite picture which appears to be pathognomonic of a disease which certainly, among ophthalmologists, has received little attention.

Dr. Garrett L. Sullivan, Boston: Any discussion of lymphogranuloma venereum would be incomplete without pointing up the confusion in terminology. To mention only some, we have such terms as lymphogranuloma inguinale, climatic bubo, Frei's disease, lymphogranuloma venereum and pudendal ulcer, and recently the term lymphopathia venereum has been proposed. In Europe, especially in France, it has been known as Nicholas Favre's disease. The first important step toward a more complete knowledge of this disease was achieved with the introduction of the Frei test in 1925. Rake, McKee and Shaeffer in 1940 obtained antigen of greatly increased concentration by culture of the virus in developing chick embryo. This is the most commonly used antigen in the Frei test at the present time. Since its introduction, this test has been widely used as an aid in diagnosis and it has been reported to elicit a positive reaction in a large percentage of patients with the disease. It should be emphasized that it is only significant of infection at some time with the virus. Recently the complement fixation test has been receiving the attention of researchers. There appears to be little doubt that Dr. Scheie's patients had had lymphogranuloma venereum at some time at least. However, the Frei reaction has been found positive in a large percentage of the Negro race. This, plus the fact that only 1 similar case has been reported in the literature, might cause one to question whether the keratitis which has been described can justifiably be termed "probably pathognomonic" of the disease. Attempts were made by Dr. Scheie in case 4 to obtain positive cultures with his biopsy material. The virus is notoriously labile and many investigators have found the optimum temperature for preservation to be —60 to —70 C. Therefore, it is suggested that the virus may have become inactivated in handling of the tissue or in preservation at a temperature possibly other than the ideal. Dr. Scheie found 6 cases reported in the literature in which Parinaud's syndrome proved to be caused by the virus of lymphogranuloma venereum. Checking the report by Levaditi and his co-workers and the report by Bollack, Basch and Desvignes gives a strong suspicion that both reports refer to the same patient. This suggests that the correct number is 5 rather than 6. If, indeed, the keratitis described by Dr. Scheie be caused by lymphogranuloma venereum, one is faced with the problem of explaining these different manifestations. Possibly the Parinaud syndrome is due to primary invasion of the eye through the conjunctiva while the keratitis might be explained on the basis of blood-borne virus.

Dr. Harold G. Scheie, Philadelphia: The incidence of keratitis due to lymphogranuloma venereum is uncertain. Lymphogranuloma venereum, as is true of other venereal diseases, has a high incidence in the tropics. Three hundred patients were admitted to the 20th General Hospital because of acute lymphogranuloma venereum. Having observed 5 patients with associated keratitis, an incidence of 1 per cent might be estimated. Actually the incidence of keratitis is probably much less than this figure because it occurs during both the acute and the latent periods of the disease. The evidence in favor of attributing the cause of this apparently distinctive type of keratitis to lymphogranuloma venereum is only presumptive because of failure to recover the virus. We do, however, believe that attention should be directed toward this condition.

Great Humanists.—An attitude is gaining ground among the profession as well as with the laity that if a man has no demonstrable defect and still persists in being ill, he should consult a psychiatrist. Or since psychiatrists are rare and such patients seem to be innumerable, he should perhaps try to find someone who for want of a better term has been called a specialist in psychosomatic medicine, and who has become especially interested in the relationships and interplay of organic and emotional disease. Such an attitude may have some justification in expediency to meet existing conditions but can do little toward the final solution of the problem. Psychosomatic medicine is medicine itself. The role of humanist cannot be assigned to any one group, whether its members be called psychiatrists, psychosomaticists or priests. The study of man and his values is at least as much a part of internal medicine as physiology, chemistry or anatomy. Fundamental concepts which involve or modify our understanding of all disease can never be regarded as clinical specialties. . . . By no means are all internists involved in these defects. Osler, Francis Peabody and many other of our predecessors were great humanists who in being so never lost their respect for science.—Barr, David P.: The Responsibilities of the Internist, *Annals of Internal Medicine,* August 1947.

A SELF-REGULATING FEEDING PROGRAM FOR INFANTS

C. ANDERSON ALDRICH, M.D.
and
EDITH S. HEWITT, M.D.
Rochester, Minn.

Considerable interest has recently been shown in the value of what has been termed the self-demand method of feeding infants. However, this term brings to mind a sort of autocratic, unlawful behavior whereas, according to our ideas, what we choose to call the self-regulating method is consonant with the democratic society of which the children are a part and with basic physiologic laws.

The data reported here have to do with the intervals of feeding chosen throughout the first year and with the appetites and attained heights and weights at 1 year of age. Information such as that concerning the formation of other habits and unapproved behavior will be reported later.

THE GROUP STUDIED

In this paper we report our experience in feeding 668 infants up to their first birthday by the self-regulating method. These comprise all the Rochester babies born in 1944 and 1945 for whom one year summaries were completed in the well-child clinics of the Rochester Child Health Project. They come from all economic strata of the city. A group of 100 infants, part of them derived from the group of 668 just mentioned, was studied more intensively to ascertain the feeding interval preferred.

INSTRUCTION OF THE MOTHERS AND DEVELOPMENT OF BABIES' HABITS

Of all babies born in Rochester, 96 per cent are delivered in St. Marys Hospital by physicians of the Mayo Clinic and immediately thereafter are placed under the care of members of the section on pediatrics of the clinic. At the same time they are registered for well-baby care under the Rochester Child Health Project. Instruction of the mothers in feeding their babies begins on the day of delivery if possible.

During the neonatal period these babies are cared for in a typical hospital nursery and are fed on a four hour schedule, except for the few babies who show outstanding need for a regimen of more frequent feedings. An earnest attempt is made to institute breast feeding, but when this is inadequate or impossible complemental and supplemental feedings are given to the babies in their mothers' arms. Feedings made up according to ordinary milk dilution formulas are given, and all the babies are allowed to take as much or as little as they desire. What has just been said does not apply, of course, to weak or premature infants.

Daily rounds are made by the staff, and all mothers are visited. Before dismissal to her home each mother is instructed in a personal interview by the fellow of the Mayo Foundation who is on service. She is told that feeding her baby will be infinitely easier at home than in the hospital, because she may feed him all he wants whenever he seems hungry. It will no longer be necessary to awaken her peacefully sleeping baby for feedings or to allow him to cry unsatisfied if he awakens before feeding time. She is told that if given a chance he will develop his own personal regularity within a few days or weeks and that her problem is to supply food and discover his innate rhythm of eating. She is invited to consult the physician by telephone when she is in doubt and to return with the baby for monthly conferences, beginning when the baby is 4 to 5 weeks of age. Four clinics are conducted weekly on a fee basis and five on a free basis. The day after the mother returns to her home a public health nurse visits her to iron out her difficulties and to give the baby a demonstration bath.

In addition to this service the mothers are given leaflets of instruction while in the hospital. These leaflets tell them what to expect of their babies at various ages up to 1 month and are designed to fill the gaps which might exist in the information given by physician and nurse. At monthly well-child conferences this technic of instruction by physician and nurse, plus printed leaflet, is continued. All records are compiled at these conferences, and observed data are supplemented with information given by the mothers.

A small group of babies included in this study were born at home or of parents who moved to this city in the course of the early months of life of the babies. They were cared for in the clinics in the same way as those who were born at St. Marys Hospital.

While at no time are mothers instructed to feed their babies according to a definite, prearranged schedule or to give prescribed amounts of food, except in an attempt to adjust to the expressed needs of the babies, mothers definitely are told what kind of foods to offer. This is necessary because the great variety of foods now available in the sophisticated menus employed in the United States is too complicated for the infant, with his primitive selectivity. A definite attempt also is made to indicate changes in the types of food and methods of feeding offered whenever the infants show themselves physiologically mature enough to accept such changes. Semisolids are offered when the babies demonstrate their ability to use the appropriate muscles for carrying food back from the mouth into the oropharynx and esophagus. Solids are given when chewing movements begin, and the cup and spoon are offered when hands begin to reach for them. Mothers are advised to continue bottle feeding until other methods are well established or until the babies begin to reject the bottle; this rejection often is delayed until well into the second year of life.

The infants are allowed considerable freedom in their selection of foods which have similar nutritional value, such as the different vegetables and fruits, and appropriate seasoning with salt is advised. Mothers are told to give, at most of the feedings, types of food which the babies prefer rather than to try to broaden the menu despite the resistance of the babies.

Furthermore, in evaluating the results shown in this paper, it should be borne in mind that we have no way of knowing exactly to what extent the mothers followed instructions. All we can say is that when mothers were so taught this is what happened. On the other hand, it is true that most of the women expressed great relief that the restraints were removed so that they could act in a more motherly way toward their babies.

No great difficulty was experienced by the physicians in the clinics in teaching the mothers how to learn the feeding rhythms of their babies. In the majority of instances mothers were surprised when they were asked if they had trouble in knowing when

---

From the Section on Pediatrics, Mayo Clinic, and Director, Rochester Child Health Project (Dr. Aldrich) and from the Rochester Child Health Project (Dr. Hewitt).

their babies were hungry. The group of babies most difficult to manage were those who suffered from "three months colic." In this difficulty we share in the perplexity experienced by all pediatricians.

While the children were under the overall supervision of experienced practitioners, much of the actual day by day instruction was given by fellows of the Mayo Foundation who were in training. The fellows are all graduates who have finished internships or residencies. Nevertheless, the setup is more nearly comparable to that found in dispensary clinics in many of our hospitals than to that found in pediatric office practice.

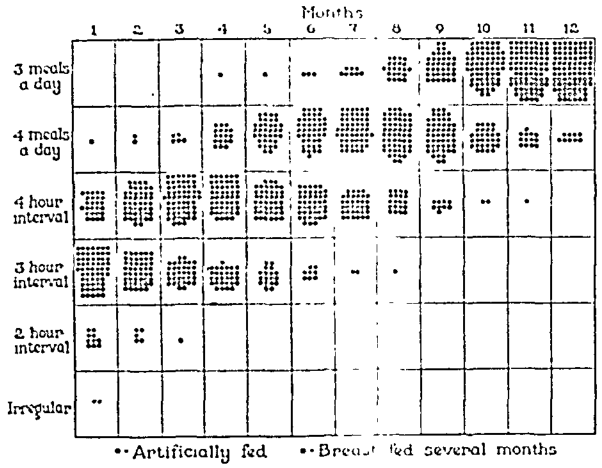

Fig. 1.—Self-regulating schedule showing trend toward the adoption of longer intervals between feedings, by more and more of the 100 infants, as their ages increased.

THE FEEDING INTERVALS CHOSEN

The group of 100 infants was studied to ascertain the intervals of feeding during each month of the first year. Forty of them were breast fed for several months, and sixty were artificially fed. Records of all were taken consecutively from our files, and the feeding intervals were charted as reported at each monthly conference (figs. 1 and 2). The intervals noted were: too irregular to state, two hours, three hours, four hours, four meals daily and three meals daily. Whenever the statement read "two to three hours" or "three to four hours" the shorter interval was tabulated. For this reason the trend from short to longer intervals is somewhat retarded in our figures over what actually happened, and the incidence of intervals of two and three hours is somewhat exaggerated.

The illustrations show that the feeding intervals of only 2 of the infants were too irregular to be graded and that these unpredictable babies put themselves on a regular schedule soon after they were 1 month of age. At 1 month of age 10 of the babies chose a two hour interval of feeding. This short interval was not used beyond the age of 3 months. Sixty-one of the infants were on a three hour schedule at the age of 1 month, while only 26 chose the more approved four hour regimen at this age. However, at 2 months of age the number of babies on the three hour regimen decreased and the number of those on the four hour schedule increased, so that the numbers in the two groups were approximately equal at that age. The number of babies on a three hour regimen continued to fall, while the number on a four hour schedule continued to increase to a peak at 3 months. The number of infants on the four hour schedule then began to decline and gave way to adoption of a schedule of four meals a day by an increasing number of infants. Change from the four hour schedule to the four meal schedule was effected by elimination of the late evening feeding. The number of babies who adopted the schedule of four meals a day reached a high plateau at the age of 7 to 9 months. This number in turn declined, to give way to adoption of the schedule of three meals a day by an augmented number of babies. The schedule of three meals a day was adopted as early as the age of 4 months by some babies, and their number continued steadily to rise until, at the age of 12 months, 91 of the infants had selected this adult feeding plan.

The trends shown in the illustrations demonstrate a definite, orderly progression from a short interval to a longer interval between feedings. In the main it appears that the usually prescribed schedules do not deviate to a great extent from the average intervals chosen by the babies.

Two points are noteworthy in this regard: first, in the early weeks of life a large majority of the babies chose an interval of less than four hours and second, it is obvious from a glance at the figures that, whereas a rigidly prescribed routine of feeding intervals could meet the requirements of the average baby it could not possibly fit the needs of those whose natural rhythms deviated greatly from such averages. Both the precocious babies, who tended to lengthen their intervals early in life, and the slower-to-change babies would be out of step. Since these deviations represent a large proportion of the total number of infants, the prescription of set schedules without regard to rhythms of individual infants must necessarily give rise to conflicts in matters of feeding.

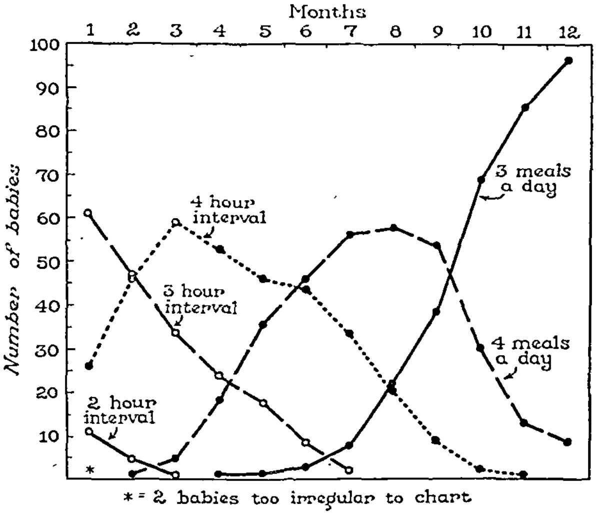

Fig. 2.—Self-regulating schedule, showing the increase or decrease, as age advanced, in the number of infants who adopted each feeding interval; the same 100 infants are represented both here and in figure 1.

THE APPETITES AT ONE YEAR OF AGE

By the method of handling feeding routines that has been described, it was hoped that we could reduce anorexia to a minimum. Accordingly, in addition to self regulation in the timing of meals the program of allowing the babies to eat as much or as little as they desired was undertaken. At the monthly conferences, mothers were instructed to feed no more of any food than the babies would take eagerly.

We are reporting a summary of the results in terms of appetite. Each mother at the one year conference was asked whether her child: (1) refused prescribed food and occasionally vomited; (2) was resistant to feeding or needed to be coaxed to eat; (3) never refused food, or (4) had a voracious appetite. Table 1 shows the result of this survey as applied to 664 of the 668 infants.

It will be observed that less than 1 per cent of the infants at 1 year of age presented frank problems as far as appetites were concerned. Approximately 7 per cent more could be placed in a borderline category, while more than 92 per cent of the babies ate extremely well.

Since we know of no accurate statistics as to the incidence of anorexia at 1 year of age, we cannot compare these figures with those of other clinics and must be satisfied to record this material without comparisons. However, we might conclude that under this sort of management an extremely large percentage of infants ate extremely well at one year of age; so that any increase in difficulty in the second year would be due to factors arising after the first birthday.

TABLE 1.—*Appetite at the End of One Year*

	Number	Per Cent
Refuses prescribed food; occasional vomiting......	6	0.9
Resistant; needs coaxing...........................	46	6.9
Never refuses food.................................	573	86.2
Voracious appetite	39	5.9
Total...	664	99.9

ATTAINED HEIGHTS AND WEIGHTS

Tables 2 and 3 show the height and weight attained at approximately 1 year of age. As it was impossible to get all the babies to the clinic on their exact birthdays, the one year summaries were computed at the visit nearest to this time. In order to be sure that this inaccuracy did not influence our average figures, we compared the average weights and heights of all those whose dates of yearly summary examination deviated greatly from the exact birthdays with the average weights and heights of those who appeared at approximately the exact anniversaries of their births. We found no significant differences.

The wide range in heights and weights is probably due to the fact that all of our premature babies were included. We consider that an average height of 29.4 inches (74.67 cm.) and an average weight of 21.8 pounds (9.9 Kg.) compare favorably with generally accepted figures. We consider it justifiable to conclude that the stature at 1 year of age was not impaired by the self-regulating technic of feeding.

SUMMARY

The care of 668 babies was supervised in well-baby clinics from the time of their dismissal from the hospital to go to their homes until their first birthdays. All these infants were put on a self-regulating regimen designed to allow the babies free choice as to intervals of feeding and amounts of food, although the kinds of foods included in the menu were prescribed. The records of these babies were studied with respect to the feeding intervals chosen by the babies throughout the first year and as to their appetite and attained stature at 1 year of age. The word stature is employed in this paper in its meaning of development or growth, which embraces both height and weight.

TABLE 2.—*Height at Approximately One Year of Age*

Height		Babies	
Inches	Cm.	Number	Per Cent
25	63.50	2	0.3
26	66.04	4	0.6
27	68.58	33	4.9
28	71.12	108	16.2
29	73.66	214	32.0
30	76.20	191	28.7
31	78.74	89	13.3
32	81.28	16	2.4
33	83.82	3	0.4
Not recorded	.....	8	1.2
Total................................		668	100.0

Maximal height, 33.0 in. (83.82 cm.)
Minimal height, 25.0 in. (63.50 cm.)
Average height, 29.4 in. (74.67 cm.)

The feeding intervals during the first month of life were classed as irregular, two hour, three hour, four hour, four meals daily and three meals daily.

The babies chose to lengthen their feeding intervals gradually, so that the average at various months agreed fairly closely with the intervals usually prescribed by physicians. However, a large majority of babies desired an interval of less than four hours in the first two months of life. Our figures show that a rigid routine, even if regulated to fit the average baby at each age, will leave a large group of infants poorly adjusted as far as timing is concerned.

At 1 year of age, 91 per cent of the babies had automatically placed themselves on a regimen of three meals a day.

TABLE 3.—*Weight at Approximately One Year of Age*

Weight		Babies	
Pounds	Kg.	Number	Per Cent
14	6.4	1	0.1
15	6.8	1	0.1
16	7.3	3	0.4
17	7.7	26	4.0
18	8.2	45	6.7
19	8.6	50	7.5
20	9.1	85	12.7
21	9.5	110	16.5
22	10.0	105	15.7
23	10.4	75	11.4
24	10.9	64	9.6
25	11.3	38	5.7
26	11.8	26	4.0
27	12.2	15	2.2
28	12.7	9	1.3
29	13.2	3	0.4
30	13.6	5	0.7
31	14.1	1	0.1
Not recorded	....	6	0.9
Total................................		668	100.0

Maximal weight, 31.0 lb. (14.1 Kg.)
Minimal weight, 14.0 lb. (6.4 Kg.)
Average weight, 21.8 lb. (9.9 Kg.)

At 1 year of age, the appetites of 92 per cent of the babies were excellent, those of 7 per cent of the babies were of borderline character and those of less than 1 per cent of the babies were poor.

The attained heights and weights of the babies at 1 year of age compared favorably with the generally accepted standards, 29.4 inches (74.67 cm.) and 21.8 pounds (9.9 Kg.).

Special Article

PLANNING FOR THE CHRONICALLY ILL

Joint Statement of Recommendations by the

AMERICAN HOSPITAL ASSOCIATION
AMERICAN PUBLIC WELFARE ASSOCIATION
AMERICAN PUBLIC HEALTH ASSOCIATION
AMERICAN MEDICAL ASSOCIATION *

The conquest of many of the acute communicable diseases has focused increasing attention on chronic diseases[1] as the major causes of death and disability. Numerous communities are now awakening to their responsibilities for the chronically ill. In eight states and at least four cities, action to meet the problem of chronic illness has already been taken or is in the planning stage.[2]

There is a great need for comprehensive planning to insure that the widespread interest in chronic disease is channeled into sound and effective activity. Such planning requires the mutual cooperation of the agencies and professions most vitally concerned with the problem. For this reason, representatives of the American Hospital Association, the American Medical Association, the American Public Health Association and the American Public Welfare Association have considered the experience already accumulated and have prepared this statement as a guide in the development of community programs. Although planning to meet the economic needs of the chronically ill is of vital importance, primary consideration is given here to the health and medical aspects of the total problem, including prevention, research, treatment and rehabilitation.

It is hoped that the general public, as well as legislators and members of the health and welfare professions, will find this statement a useful guide and stimulus to planning for the chronically ill.

EXTENT OF CHRONIC ILLNESS

Chronic illness affects nearly every family. It has been conservatively estimated that about 25 million persons, more than a sixth of the population, have a chronic disease.[3] Some 7 million of these have appreciable disability from their illness,[4] while 1½ million are invalids.[5] The most important of the chronic diseases are heart disease, arteriosclerosis, high blood pressure, nervous and mental disease, arthritis, kidney disease, tuberculosis, cancer, diabetes and asthma.[6] Because special provisions have been made for patients with tuberculosis and mental disease, they are not included in the scope of this statement.

Each year chronic diseases cause nearly a million deaths and are responsible for the loss of almost a billion days from productive activity.[3] Appropriate action can prevent much of this staggering loss to our economy.

Although the prevalence of chronic diseases increases with age, and the progressive aging of our population is one of the factors responsible for the growing importance of the problem, it must be borne in mind that chronic illness occurs at all ages. Fully one half of the chronically ill are below the age of 45, and 16 per cent of them are under 25. More than three fourths are persons in the productive years from 15 to 64.[3]

Chronic illnesses in childhood and adolescence are particularly important because they influence the period of growth as well as the entire period of adult life. They may have serious effects on the emotional development and social adjustment as well as on the education of their young victims.

PREVENTION

The basic approach to chronic disease must be preventive. Otherwise the problems created by chronic diseases will grow larger with time, and the hope of any substantial decline in their incidence and severity will be postponed for many years.

There is a need to intensify health department programs to control chronic communicable diseases such as tuberculosis, syphilis, hookworm and malaria. Accident prevention programs —in industry, on the farm and in the home—should be greatly expanded to reduce the incidence of physical handicaps.

The promotion of optimal health throughout life is an important factor in the prevention of chronic illness. Child and school health programs need to be strengthened. Wide expansion of nutrition, mental health and housing programs can have important effects in decreasing the incidence of chronic illness.

The success of programs to conserve the health of infants and children suggests the possibility of achieving effective health programs directed to adolescents as well as adults. The health programs of our high schools and colleges, including medical examinations and correction of defects, physical fitness and recreational programs and health education require intensive development.

The periodic medical examination of apparently well persons needs to be explored on a new basis, including selective laboratory and clinical examinations chosen for particular age, sex, geographic and occupational groups. These include the serum reaction, chest x-ray, urinalysis, electrocardiography and ophthalmoscopic and other examinations.[7]

Industry and labor can play an important constructive role in this connection by encouraging health examinations of employees, including laboratory procedures, on a much larger scale than at present.

The recent development of special phases of the health examination, particularly in the fields of tuberculosis control and cancer detection, is especially noteworthy. The great interest shown by the medical profession and the public in chest x-ray surveys and in the establishment of diagnostic centers to examine apparently well persons for early signs of cancer represents a distinct advance in preventive medicine. It may well initiate a basic shift in emphasis in the medical care of adults comparable to that which has occurred in obstetrics and pediatrics, in which preventive supervision and examination of presumably well persons is a major requirement of good medical practice. There is a need to explore the practical possibilities of preventive examinations to discover all possible disease, making full use of the diagnostic aids developed by modern medical technology.

RESEARCH

Further advances in the prevention as well as the treatment of many chronic diseases are dependent on research. Although a good deal of research is now being carried on in chronic disease, only a fraction of the total need is being met.

War experience in medical research has made it clear that we must broaden our vision and think in terms of research planned and organized on a much larger scale than any now contemplated. This requires the training and support of a much larger corps of medical scientists and the development of teams of research workers to carry forward coordinated programs. The greatest emphasis must be placed on those

---

* See Report of Reference Committee on Miscellaneous Business of the House of Delegates in The Journal, July 5, 1947, p. 883.

1. The term "chronic disease" is susceptible of various definitions. This has been suggested as an administrative definition of chronic disease: "A disease that may be expected to require an extended period of medical supervision and/or hospital, institutional, nursing or supervisory care" (Rogers, E. S.: Chronic Disease: A Problem That Must Be Faced, Am. J. Pub. Health **36:** 345 [April] 1946). In the National Health Survey, chronic disease was defined for statistical purposes as " a disabling or nondisabling chronic pathologic condition known to the informant, the symptoms of which had been recognized for at least three months" (Perrott, G. St. J.: The Problem of Chronic Disease, Psychosom. Med. **7:** 22 [Jan.] 1945). Another definition is that used for survey purposes by the Public Welfare Council of Connecticut: "a disease or condition of the body or personality which has been present at least six months or which may be expected to continue at least six months and which interferes with one's occupation and normal physical and social life" (Need for a State Infirmary for the Care and Treatment of Aged, Infirm and Chronically Ill Persons, Public Welfare Council, Hartford, 1944, p. 4).

2. The states referred to are California, Connecticut, Illinois, Indiana, Maryland, Massachusetts, New Jersey and New York. The cities are Chicago, Cleveland, Milwaukee and New York.

3. Perrott.[1] The estimates given are admittedly low because of the survey technic used.

4. National Health Survey, Some General Findings as to Disease, Accidents and Impairments in Urban Areas, Pub. Health Rep. Reprint No. 2143, p. 2 ff. The frequency of chronic illnesses causing disability of at least seven consecutive days in a twelve month period was found to be 48 per thousand persons, or approximately 7 million for the total population.

5. The Magnitude of the Chronic Disease Problem in the United States, National Health Survey, Sickness and Medical Care Series, Bulletin 6, p. 6.

6. Importance was determined by the combined indexes of prevalence, mortality, disability and invalidism. See reference 5, p. 7.

7. Roemer, M. I.: A Program of Preventive Medicine for the Individual, Milbank Quart. **23:** 209 (July) 1945

diseases which are the most important causes of death and disability, such as heart disease, high blood pressure, arteriosclerosis, arthritis, kidney disease, cancer, diabetes and asthma.

Research institutes in chronic disease, associated with clinical facilities, may well become the basic units of such a program. In New York City the research services of the Goldwater Memorial Hospital have carried on important research in kidney disease, arteriosclerosis, malaria and cirrhosis of the liver.[8] In Illinois the State Commission on the Care of Chronically Ill Persons is considering the advisability of developing a state supported university research institute for the study of chronic illness which would, in addition to suitable research facilities, provide beds for 200 patients and an outpatient service for 15,000 patients a year.[9] The National Institute of Health is formulating plans for intensive laboratory and clinical research in heart disease, geriatrics, cancer and mental disease.

There is a great need for administrative research, for more precise information on methods of providing the necessary services for the chronically ill. Basic research on some of the administrative problems is already being undertaken,[10] but the field is a relatively new one and requires intensive study and development.

Research is necessary also in the social and psychologic aspects of chronic illness. The influence of these factors in the development of specific chronic diseases needs to be more fully determined, while the effect of chronic illness on the individual's social relationships needs further study.

MEDICAL CARE

In the past, the approach to chronic illness has been primarily concerned with institutional care for advanced stages of disease. There is need for a new orientation which places major emphasis on the early stages of chronic illness with a view to preventing or at least delaying the progress of the disease process.

Diagnosis and treatment of illness at its inception is essential to the control of chronic disease. Competent medical supervision, if brought into play early enough, can have an important preventive effect. The most dramatic expression of this fact found in cancer control, where diagnosis of early symptoms prompt treatment may be a life saving measure. Early [illegible]osis and proper management of diabetes prevents the serious complications of infection, gangrene and coma. Similarly, early diagnosis and treatment may prevent complications or prolong the lives of persons with heart disease, hypertension, rheumatic fever, peptic ulcer and other chronic diseases.

The barriers to early competent diagnosis and treatment must be removed. This requires the construction of hospital and laboratory facilities to cover all our communities, with coordination of facilities to insure a maximum of diagnostic and therapeutic effectiveness for the individual patient. Health and medical agencies need to plan to fill the great needs for personnel as rapidly as possible. Means must be found to remove the basic economic barriers to early diagnosis and therapy.

Health departments, which have carried on excellent educational activities in communicable disease, should turn in increasing numbers to the larger field of chronic illness and teach the public the facts about heart disease, cancer, diabetes and other chronic diseases, with special emphasis on early signs and symptoms and the importance of early and continued medical supervision.

The concept of medical care must be broadened to include the social factors which play a vital role in the progress of chronic illness. Physicians have learned, for example, that it is not enough to cure a patient with minimal tuberculosis and send him back into the community. On the contrary, he must be observed carefully over a long period for signs of reactivation of the disease process. Even more important, the physician must draw on community resources in order to change the patient's environment to prevent breakdown. If the patient's previous occupation called for strenuous physical exertion, he should be retrained for office work or some other light occupation so that he can live with his tuberculosis or other chronic disease. Occupational retraining and job placement are essential therapeutic and preventive measures.

Several general considerations should be borne in mind in planning to provide adequate medical care for the chronically ill:

First, the care of the chronically ill is inseparable from general medical care. While it presents certain special aspects it cannot be medically isolated without running serious dangers of deterioration of quality of care and medical stagnation.

Second, major emphasis must be given to coordination and integration of services. The person who is chronically ill will receive the type of care which he specifically needs only if provision has been made for the highest possible degree of coordination. Since the medical condition of the chronically ill person is not static but changes with time, it is essential to develop smoothly operating mechanisms for referral from one type of care to another.

Third, facilities for the care of the chronically ill should be planned for the community as a whole and not for the indigent alone. Chronic disease strikes all sections of the population, and the lack of facilities is as great for those who are able to pay as for those who cannot. The facilities for chronic disease should be community institutions serving all sections of the population. They will in this way achieve a greater degree of financial stability because of the additional income from those able to pay, and will be able to furnish a higher quality of care.

Fourth, the services and facilities necessary for the medical care of the chronically ill require considerable and continuing financial expenditures in order to maintain the quantity and quality of care offered. Good medical care for chronic illness cannot be purchased on an "economy" basis.

Fifth, and most important, the goal of medical care is to maintain and restore the chronically ill as independent and self-supporting members of the community. Major emphasis should be placed on home and office care, with hospital care, convalescent care and rehabilitation serving where possible to return the chronically ill to productive community life, and with nursing home facilities providing for those whose medical condition is such that they cannot remain in their home environment.

HOME CARE

The majority of persons who are chronically ill can best be cared for in home, office and clinic.

It is unwise as well as unpractical to consider a separate home, office or clinic service for the chronically ill; their needs are best met by inclusion in the general community medical care program.

Ready access to diagnostic and specialist service is essential to adequate care for chronic diseases, since many of them are difficult to diagnose and treat.

One of the most pressing needs is for an expansion of public health nursing service to provide bedside and other nursing services for the chronically ill. Most rural communities and small cities do not have sufficient public health nurses to provide adequate bedside nursing care. Some of the larger cities have well organized bedside nursing programs, but even here the number of nurses is generally below the estimated minimum of 1 nurse to 2,000 persons to carry out all public health nursing activities, including bedside care.[11] In addition to increasing the number of public health nurses, there is need to train them to provide valuable assistance to physicians in the time consuming task of educating the individual patient in the proper understanding and management of his chronic illness.

Much wider use should be made of practical nurses and nurses' aides, working under the supervision of the public health nurse, for duties which do not require the training and experience of a graduate nurse.

Housekeeper service should be widely encouraged; there has already accumulated ample experience to show the value of the visiting housekeeper in the home care of chronic illness.[12] Housekeeper service performs the important social function of enabling the chronically ill patient to remain at home and has an economic value in helping to reduce the need for expensive institutional facilities.

[8] Research, An Experiment in Municipal Organization, Department of Hospitals, New York City, 1945, p. 48 ff.

[9] Communication from R. M. Hilliard, public aid director, state of Illinois.

[10] The Central Service for the Chronically Ill in Chicago is making a detailed study of the needs and costs of care *of different categories of* nursing home patients.

[11] Resolution of the National Organization for Public Health Nursing, June 1944, Public Health Nursing **37**, No. 3, January *1945*.

Other measures which enable chronically ill persons to be cared for at home include improved housing, supervised boarding homes, medical social service, recreational and occupational therapy, and vocational rehabilitation. Social security measures to maintain income such as disability insurance, old age insurance and public assistance are likewise of vital importance.

HOSPITAL CARE

The large number of chronically ill persons in general hospitals who require long-term care represents a serious problem to hospital administrators.[13] The general hospital as at present constituted is often unsuited to the care of long term patients, since it is geared primarily to the therapeutic and general requirements of the acutely ill. It may lack adequate departments for physical therapy, occupational therapy and rehabilitation, as well as sun porches, recreational facilities, educational facilities for children and an understanding of the social and psychologic needs of the chronically ill.

The average long term patient requires less costly care than that provided in the acute general hospital.[14] To continue to care for the long term patient in the acute general hospital is wasteful; it provides care which is more expensive than he actually needs and which is often unsuited to his requirements.

The construction of hospital facilities for the chronically ill has been encouraged by the passage of the Hospital Survey and Construction Act, which provides federal aid for such facilities up to a maximum of two beds per thousand of population.[15]

There is already evident a tendency in some localities to build chronic disease hospitals in areas remote from the medical center and the general hospital and with no relation to them. This trend unfortunately follows the pattern already laid down in the construction of our tuberculosis and mental hospitals, a pattern which has resulted in many instances in the medical isolation and stagnation of these special institutions.

Hospital facilities for long term illness should be build in the very closest relation to teaching centers and general hospitals.

The specialized chronic disease hospital is suitable in large cities, where it can be located on the grounds of or very closely related to a medical school or teaching general hospital. Special consideration should be given to planning the facilities for children who are chronically ill. While an official or voluntary organization may be responsible for the construction and maintenance costs, the medical school should provide the attending and resident staff and utilize the facilities for research and medical education in chronic disease.

It is important that the specialized chronic disease hospital serve as the consultation center for chronic disease in its medical service region.[16] It should maintain formal professional affiliation with general hospitals in the region that care for chronic patients in order to provide consultation and teaching visits from the center to the general hospitals as well as the referral of patients to the center for special study.

Most patients with chronic illness that require hospitalization are best cared for in a unit of the general hospital especially designed to meet their needs. This arrangement encourages patients to seek and use care, since it is near their homes, families and friends, makes available to them the existing facilities of general hospitals, provides opportunity to interns, nurses and staff for experience and teaching in chronic disease, avoids expensive duplication of existing general hospital facilities and affords the most ready means of transfer to and from the acute and chronic disease sections of the hospital when needed. Further, it allows for greater flexibility in hospital planning by making it possible for future, unforeseen shifts in the relative proportions of patients with acute and chronic diseases to be met by changing the designated use of either chronic or acute beds in the same hospitals.

Many advantages of this plan would be lost if the chronically ill were simply intermingled with all other patients in general hospitals. The provision of a special wing or floor devoted to long term patients insures that the special needs and problems of chronic disease are not lost sight of in competition with the more urgent and dramatic needs of the acutely ill. It makes possible the planning of the special unit in conformity with its special purpose, both as to architecture and as to staff. It makes it easier to provide occupational and recreational therapy, special physical therapy, rehabilitation and other services essential to the care of long-term patients. It facilitates a more economical use of nursing personnel, the utilization of a larger proportion of attendants and less intensive medical staff attendance than is needed in the section of the hospital devoted to patients with acute illnesses.

Under no circumstances should chronic disease hospitals or units be limited to the indigent. The lack of facilities is felt by all sections of the population. High standards will be maintained most effectively if the facilities are geared to meet the requirements of the entire community. Also the admission of patients who are able to pay will reduce the need for tax funds. It must be recognized, however, that prolonged illness exhausts the financial resources of many patients, necessitating payment of tax funds for their care.

CARE IN NURSING HOMES

Chronically ill persons who need active and continuous medical care should be treated in a hospital. On the other hand, there are many chronically ill persons who are more or less disabled by their illness, whose requirements for care can be met by practical nurses and attendants with medical and nursing supervision and who cannot or should not remain at home. Care for such persons should be provided in nursing homes.

The following example may make the difference clear: A person who has suffered a cerebral hemorrhage with paralysis of one side of his body requires hospital care. This care will extend over a period of weeks and months, during which time he will receive intensive physical therapy to restore the maximum possible use of his muscular system. When no further improvement can be obtained by medical treatment and he is left with a good deal of disability which makes it impossible for him to be cared for at home, he is eligible for care in a nursing home.

Nursing homes, both private and public, should be brought under state licensure laws in which provision is made for minimum standards and regular inspection. The minimum standards should require continuing medical supervision, including complete medical examinations of patients prior to admission to the nursing home and follow-up examinations at definite intervals, as well as physician visits on a regular basis and on call. The standards should call for a sufficient number of practical nurses and attendants to meet the full needs of the patients. They should provide for at least one full time graduate nurse in charge of nursing care.[17] The standards should require facilities for recreation and occupational therapy, for a maximum of privacy and individual attention, and for cheerful and homelike surroundings. Construction should meet adequate standards of safety and sanitation.[18]

---

[12] Jarrett, M. C.: Housekeeping Service for Home Care of Chronic Patients, Welfare Council of New York City, Dec. 31, 1938.

[13] The percentage ranges from 7 to 20, depending on the area surveyed. In New York City in 1928 a fifth of the ward beds in both private and municipal general hospitals were occupied by chronic patients (Jarrett, M. C.: Chronic Illness in New York City, Columbia University Press, 1933, vol. 1, p. 119). In New Jersey in 1940 thirty-eight general hospitals reported that 7 per cent of the total number of patients were chronically ill (Frankel, Emil: New Jersey Studies Problems of Care for the Chronically Ill, Hospital Management **50:** 19 [Aug.] 1940). The findings to date in the Illinois State Health Department's survey of hospital facilities indicate that about 15 per cent of the beds in the general hospitals of the state are occupied by chronically ill patients (unpublished data).

[14] The cost at Montefiore Hospital, a high standard voluntary chronic disease hospital in New York City, is more than two-thirds the cost in acute general hospitals (communication from Dr. E. M. Bluestone, director). In 1945 the cost at Goldwater Memorial Hospital, a municipal chronic disease hospital in New York City, was one-half the average cost in the acute general municipal hospitals (communication from Dr. E. M. Bernecker, commissioner of hospitals of New York City).

[15] Public Law 725, 79th Congress, sec. 622 (b).

[16] Planning for the Care of the Chronically Ill in New York State—Regional Aspects, New York State Health Preparedness Commission, Albany, 1946. Health Service Areas, Public Health Bulletin 292, U. S. P. H. S., Washington, 1945.

[17] The present shortage of nursing personnel makes it impossible in many instances to meet this requirement. The New Jersey State Department of Institutions and Agencies has met the situation by helping nursing home operators to make arrangements for a daily supervisory visit from the local visiting nurse association. The plan seems to be working very well.

Private Nursing Homes

Experience has demonstrated that improvement in the quality of private nursing homes cannot be obtained merely by passage of a licensure law. The power to inspect and license nursing homes carries with it the responsibility for carrying on an intensive educational campaign, working with the individual nursing homes to improve the care given. The device of placing each new nursing home on a six month probationary period, during which time there is a great deal of educational assistance from the licensing agency, has been demonstrated to be an effective method of raising standards.[19]

It is suggested that, wherever possible, the quality of medical and nursing supervision can be greatly improved through arrangement with the medical board of a nearby hospital to provide the necessary medical services.

One of the most serious drawbacks to adequate care by private nursing homes is the low payments made by welfare agencies for clients requiring nursing home care. A sharp upward revision of payments by welfare agencies, to bring them up to the actual cost of care, is an indispensable prerequisite to raising standards. At the federal and state levels, liberalization or elimination of the ceiling on payments for public assistance clients is indicated.

Public Nursing Homes

The realization that a large proportion of the population of county homes or almshouses consists of chronically ill adults has led to a widespread movement to convert them into public nursing homes.

It is clear that such conversion does not make the almshouse a chronic disease hospital but rather a nursing home for the chronically ill.

County homes should be converted into public nursing homes only if their physical facilities are adequate, if they are within reasonable distance of general hospitals with which close medical relationships are maintained, and if the responsible authorities are prepared to meet the minimum standards described previously: namely, adequate medical and graduate nursing supervision; sufficient personnel to meet the full needs of the patients, including medical social service if possible; provision for privacy, a cheerful and homelike atmosphere and recreational and occupational therapy and construction which meets safety and sanitation requirements. Many county homes cannot meet these conditions and should therefore not be considered for conversion.

It is suggested that conversion be planned on a statewide basis, with the most careful evaluation of the suitability of individual almshouses for conversion. Financial and technical assistance by the state to localities planning conversion will make it possible to achieve higher standards of care. Public nursing homes should be included in the provisions of nursing home licensure laws.

A factor which will help obtain increased community interest, better administration and higher quality care in public nursing homes is the admission of patients able to pay part or all of the cost of care. There is a considerable demand for public nursing home care on the part of patients able to pay. By opening its facilities to such patients the public nursing home will not only improve its financial position but perhaps begin to free itself from the almshouse tradition and serve as a public facility for the entire community.

The Social Security Act should be amended to allow federal matching to states for assistance to patients who wish to enter public medical institutions, including nursing homes, that meet adequate standards. Payment for nursing care in public as well as private homes should be commensurate with the actual cost.

New Institutions

The shortage of institutions for nursing home care of the chronically ill cannot be met by present facilities or by the conversion of county homes. There is a definite need for new construction.

It is recommended that voluntary and governmental general hospitals which have chronic disease pavilions give serious consideration to establishing nursing home facilities for the chronically ill. These facilities should be built on the grounds of the general hospital or within a reasonable distance. There should be close administrative, medical and nursing relationships between the hospital and the nursing home.

The specialized chronic disease hospitals located in teaching centers should likewise maintain nursing homes which can be utilized for research and training and will set standards of quality of nursing home care.

The construction of new institutions should be closely integrated with state plans for reconversion of public homes and utilization of private nursing homes in order to prevent an overabundance of facilities in some areas and lack of facilities in others.

CONVALESCENCE AND REHABILITATION

Undoubtedly the most neglected aspect of chronic illness is that of convalescence and rehabilitation.

Only recently has there been recognition of the fact that convalescent care is an important feature of the care of the chronically ill. Chronic diseases often run a course of many years, with periods of relative well-being alternating with periods of illness. Following a flare-up of illness, adequate convalescent care may lead to complete or partial rehabilitation and may help delay the progress of the underlying chronic disease. Such convalescent care undoubtedly conserves hospital beds and performs important therapeutic and preventive functions. Examples of chronically ill persons requiring convalescent care would include those recovering from a period of heart failure, an attack of acute rheumatic fever or a flare-up of arthritis. Then there are persons who have a chronic illness such as diabetes or heart disease and develop pneumonia or some other acute illness and need convalescent care after recovery from the acute illness.[20]

There has been a large growth of convalescent homes for children with rheumatic heart disease and other crippling conditions. It is essential that such convalescent homes be located near enough to general hospitals to permit close professional relationships and adequate medical supervision.

Convalescent homes for adults have never been developed to any appreciable extent in the United States. Most convalescent care for adults is now provided in nursing homes which also care for nonconvalescent patients. On the whole, there has been insufficent appreciation of the value of convalescent care and rehabilitation in the care of the chronically ill.

Recent experience with planned convalescence and rehabilitation in the armed forces has demonstrated their great potential usefulness. By providing physical reconditioning, educational training, recreational activities and vocational guidance it was found possble to shorten the period of hospitalization, reduce the incidence of recurrences and return a larger proportion of men to active duty.[21]

Planned convalescence and rehabilitation are particularly important in chronic disease. The chronically ill have to be made conscious of their limitations early in the course of the disease, and many of them must be retrained for new occupations so that they may stay within the limits of activity prescribed by their illness and yet maintain their economic independence.

---

[18] A detailed description of minimum standards of nursing home care is given in Institutional Care of the Chronically Ill, a report issued by a joint committee of the American Hospital Association and American Public Welfare Association in January 1940.

[19] Potter, E. C., and others: Inspection and the Power of License as Tools in the Care of Chronically Ill, Public Welfare **2:** 100 (April) 1944.

[20] Boas, E. P.: Convalescence and Chronic Illness, from Proceedings of Conference on Convalescent Care, New York Academy of Medicine, Nov. 9, 1939, p. 38.

[21] Rusk, H. A.: Planned Convalescence, Bull. New York Acad. Med. **22:** 465 ff (Sept.) 1946.

Probably the first steps along these lines will be taken by university hospitals, some of which have already made plans for rehabilitation centers as an integral part of their medical program.

In 1943 Congress broadened the scope of the national rehabilitation program. As a result, state rehabilitation agencies were able to rehabilitate successfully nearly 42,000 persons in 1945. These were generally persons with long standing chronic impairments and illnesses—orthopedic disabilities, speech, hearing and sight defects, poliomyelitis, tuberculosis, mental disease, heart disease, asthma, hernia and other conditions.[22] That the need is still far from being met is indicated by the fact that the estimated backlog of persons in need of and entitled to such service is between 1½ and 2 million.[22]

Of the 42,000 disabled persons who were successfully rehabilitated in 1945, nearly 79 per cent were unemployed at the time of applying for rehabilitation service and 18 per cent had never been employed. The average yearly income before rehabilitation, including those who received assistance from public or private sources, was $288. The average annual wage after rehabilitation was $1,764. The total income of the group was increased by rehabilitation from 12 million dollars a year to 74 million, a sixfold increase.

In the past, many of the disabled have had to be supported by public or private assistance at a cost up to $500 a person each year. Vocational rehabilitation costs an average of only $300 a person, and this cost is not repeated.[23] On the contrary, rehabilitation changes the individual into a self-sustaining productive member of the community. It is clear that rehabilitation is economically and socially sound.

The results achieved with long standing chronic impairments and diseases point up the great potentialities of rehabilitation instituted early in the course of chronic illness.

COORDINATION OF SERVICES

The problem of chronic disease presents many aspects—prevention, research, medical care in home, hospital and nursing home, and convalescence and rehabilitation.

Undue emphasis on any one aspect would be unwise, uneconomical and ineffectual. For example, to concentrate on the provision of medical care without paying serious attention to prevention and research would postpone for many years any basic attack on the problem. On the other hand, it is impossible to focus sole attention on research because of the very urgent need for medical care. Likewise, to provide hospital beds for chronic disease without making nursing home facilities available would result in many beds being occupied by patients who do not need hospital care. Too great an emphasis on nursing homes would deprive many patients of the specialized hospital care which is necessary for their improvement. Failure to plan adequately for home care or for convalescent care and rehabilitation would defeat the purpose of the program—to maintain and restore the individual as a self-supporting productive member of his community.

There is a great need for cooperation and coordination of the numerous agencies concerned with chronic disease: health, welfare and education departments, hospitals, medical societies, medical schools, social agencies, rehabilitation services, nursing homes. In some communities this coordination has been achieved through the establishment of central planning and coordinating bodies which study the various aspects of the problem, make the facts known to authorities and the public, stimulate needed services, assist in securing necessary facilities and act as information centers for patients, physicians, and health and social agencies.[24]

The total problem of chronic disease is not a series of separate problems which can be solved one by one but rather a complex of interrelated problems which require simultaneous solution. It is recommended, therefore, that coordinated and comprehensive planning be undertaken at all levels in order to achieve effective action to meet the challenge of chronic illness.

Clinical Notes, Suggestions and New Instruments

GUMMA OF THE VAGINA

WALTER J. REICH, M.D.
and
MITCHELL J. NECHTOW, M.D.
Chicago

This report concerns a case of gumma of the vagina. Syphilis of the vagina is not common, especially the gummatous lesion. The history of syphilis probably begins with Ambroïse Paré (1510-1590) who, according to Pusey, employed a vaginal speculum to study the vaginal and uterine lesions of venereal disease. The resistance of the squamous epithelium of the vagina to syphilitic infection and the coincident biologic reasons have been the subject of considerable comment from numerous syphilologists.

According to Gellhorn and Ehrenfest,[1] the literature of Lancereaux (1868) does not contain any positive records of tertiary manifestations of syphilis of the vagina, which must be rarer than the exceptional primary and secondary lesions.

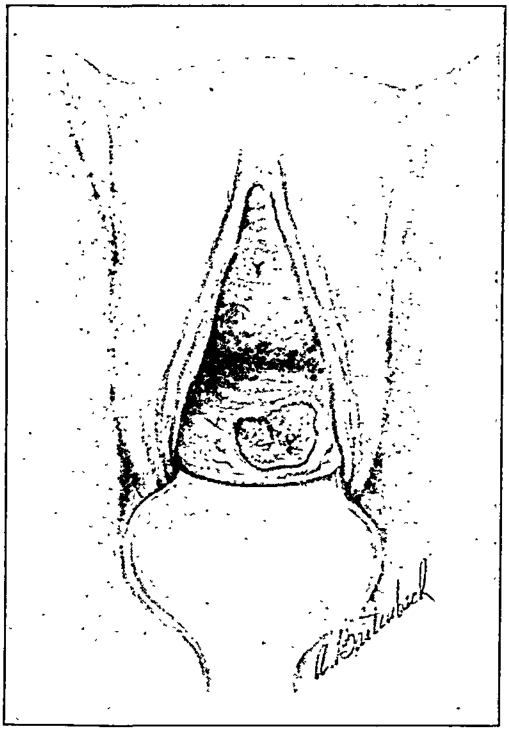

Fig. 1.—Drawing showing the gumma on the posterior vaginal wall.

In 1877 Birch-Hirschfeld described a case of diffuse gummatous perivaginitis. Neumann up to 1896 had seen only 3 cases of vaginal gummas. Oppenheim[2] in 1908 described a syphilitic tertiary ulcer of the vagina. The most recent record of a tertiary ulcer of the vagina is that of Ballog[1] in 1914.

Tertiary syphilitic manifestations originate extremely infrequently in the vagina. The isolated submucous gumma breaks down early and appears in the form of a characteristic ulcer.

Pusey has stated that tertiary lesions occur only in tissue in which foci of infections have been planted during the secondary period. Gummas of the cervix have been reported in fairly large number.

2. Oppenheim, M.: Atlas der venerischen Affektionen der Portio vaginalis uteri und der Vagina, Leipzig, F. Deuticke, 1908.

According to Becker and Obermayer[3] tertiary lesions are rare, and they do not discuss them at any length. Up to 1916 Gellhorn and Ehrenfest recorded only 50 authentic cases of primary lesions in the vagina in their survey of world medical literature. Stookey[4] reported only 2 cases of primary lesions of the vagina and none of the tertiary lesions.

REPORT OF CASE

History.—M. W., a Negro woman aged 60, was admitted Dec. 12, 1945 and discharged Jan. 25, 1946. On admission the tentative diagnosis was carcinoma of the vagina. The patient complained of pain in the lower part of the abdomen and of an odorous vaginal discharge for the past four weeks. She stated that she was well until these symptoms became apparent. The discharge became more pronounced when she was up and about; weakness accompanied the leukorrhea and pain.

Past History.—The menopause occurred when the patient was 47 years of age. She had had nine pregnancies with six living children. She had had no serious ailments, and the balance of the history was noncontributory.

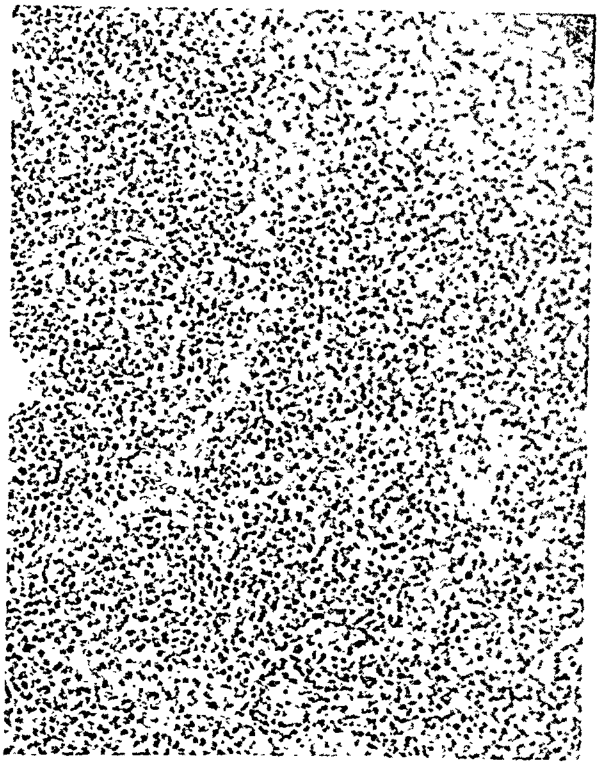

Fig. 2.—Photomicrograph showing the histopathologic structure of the gummatous lesion (magnified × 180).

Physical Examination.—Physical examination revealed a Negro woman who appeared asthenic but not acutely ill. The blood pressure was 130 systolic and 90 diastolic, the temperature 98 F. and the pulse rate 88. The pupils were unequal; the right was larger than the left and did not react to light and accommodation. Multiple bony exostoses of the forehead were present.

Pelvic Examination.—Pelvic examination revealed a multiparous vaginal introitus. The external genitalia did not manifest any gross pathologic conditions. Bartholin's gland, Skene's ducts and the urethra were essentially normal. The posterior portion of the vaginal vault revealed on palpation an irregular, crater-like lesion, measuring 3 to 4 cm. in diameter, with firm margin and edges, the center of which felt soft; it was tender on palpation (fig. 1). Examination with the speculum exposed the lesion distinctly: it exuded a mucopurulent foul-smelling discharge. The remainder of the vaginal mucosa did not appear to be affected. This lesion did not stain with strong solution of iodine. Rectal examination failed to disclose any connection between this lesion and the rectum. The remainder of the examination of the pelvis did not disclose any gross pathologic conditions.

The impression was that of a primary carcinoma of the vagina.

Biopsy.—A biopsy specimen was taken from several areas, and the report submitted from the surgical pathology laboratory revealed the following: The tissue showed vascular granulation infiltrated by lymphocytes, many mononuclear cells, a few eosinophils and plasma cells (fig. 2). The endothelium of blood capillaries was swollen. This was a syphilitic gummatous lesion.

Laboratory Data.—The Wassermann and Kahn serologic tests were positive. Urinalysis was negative for sugar and albumin. The hemoglobin level was 60 per cent. The red blood cell count was 3.9 millions.

Treatment and Course.—This patient was referred to the venereal disease clinic. She was treated with antisyphilitic agents, and the lesion disappeared.

SUMMARY AND CONCLUSION

1. A case of a gumma of the vagina is reported.
2. The world literature is sparse in authentic reports of such cases.
3. Probably because of both the biologic reasons and the resistance of the epithelial lining of the vagina few cases of syphilitic lesions are observed.
4. The gross appearance of this lesion simulated that of a primary carcinoma of the vagina.

SENSITIZATION TO THE PRESSOR ACTION OF EPINEPHRINE ("ADRENALIN")

A Warning Concerning the Use of Epinephrine as an Antidote After the Administration of Tetraethyl Ammonium Chloride

IRVINE H. PAGE, M.D.
and
R. D. TAYLOR, M.D.
Cleveland

The recent widespread interest in the action of tetraethyl ammonium ion as the result of the work of Acheson with Moe[1] and Pereira[2] in demonstrating its selective blocking of transmission of impulses across sympathetic ganglions has led to its clinical trial in a wide variety of vascular disease. We,[3] as well as Lyons and associates,[4] have been particularly interested in its action in hypertensive patients, and it is with these that this communication is concerned. Epinephrine ("adrenalin" N. N. R.) has been recommended as the antidote of choice after excessive doses of tetraethyl ammonium chloride. Acheson and Moe[1] have shown that in cats with spinal block induced by this drug the response to epinephrine was at least unaffected.

During the course of experiments to determine the effect of tetraethyl ammonium chloride on the blood pressure of hypertensive dogs, there was occasion repeatedly to test the response to epinephrine before and after administration of the former drug.

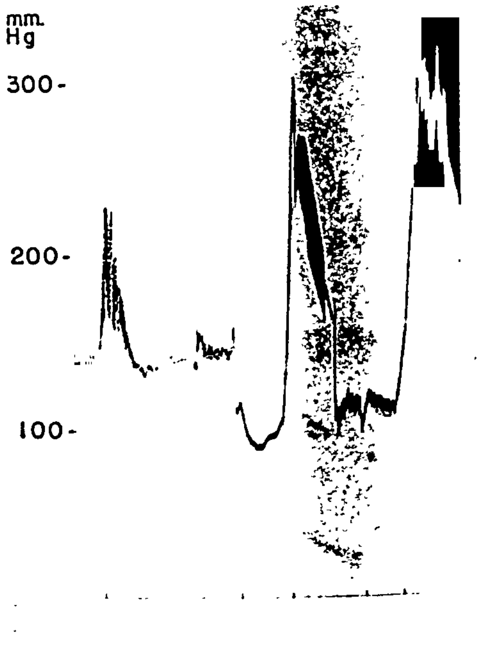
Dogs were anesthetized with pentobarbital sodium, arterial pressure recorded from the femoral artery and injections made into the femoral vein. Test doses of epinephrine hydrochloride (0.2 cc. of 1:20,000 solution) were followed by a single dose of 100 mg. of tetraethyl ammonium chloride. When the blood pressure had begun to rise after its maximal fall, the same dosage of epinephrine was repeated. Instead of producing the usual rise in blood pressure, varying from 30 to 50 mm. of mercury, the drug augmented it several fold. Rises of 100 to 150 mm. of mercury or more were not unusual (see the accompanying illustration). This dramatic sensitization to epinephrine seems to occur regularly. A test dose of nicotine after the administration of tetraethyl ammonium chloride resulted in little or no response. It is of physiologic interest that hepatectomy not only reduces the response to epinephrine hydrochloride but blocks the augmenting action of tetraethylammonium chloride (unpublished observation with Dr. J. J. Reinhard).

Since the dose of tetraethyl ammonium chloride (100 mg. in dogs weighing from 9 to 12 Kg.) is well within the range used in human beings, it has seemed desirable to warn of the possibility that a safe antidotal dose of epinephrine may be much less than usual after tetraethyl ammonium has been administered. Sensitization to epinephrine is much more prominent in dogs anesthetized with pentobarbital sodium than in unanesthetized animals.



Sensitization to epinephrine and renin in a dog under anesthesia with pentobarbital sodium. First injection, epinephrine 0.2 cc. in 1:20,000 dilution; second, tetraethyl ammonium chloride 100 mg.; third, same dose of epinephrine; fourth, nicotine 0.15 cc. in 1:1,000 dilution; fifth, renin. The control injection of renin is not shown; the rise in arterial pressure was 46 mm. of mercury.

It is easily conceivable that patients with cardiovascular disease, especially those with coronary or cerebral lesions, might be seriously injured from a sudden and severe rise in arterial pressure with vasoconstriction of the degree possible after sensitization due to the administration of tetraethyl ammonium.

The mechanism of the sensitization is uncertain. It might be suggested that it is an explosive manifestation of sensitization of denervation demonstrated by Elliott[5] in animals and by Freeman, Smithwick and White[6] in man. In animals, however, this phenomenon is said to appear between one and two weeks after denervation, while in man six to eight days are required: tetraethyl ammonium sensitization is immediate. It is also possible that amine oxidases are in some way blocked by tetraethyl ammonium ion, since the response not only to epinephrine but to renin and angiotonin is also greatly augmented.[7]

The Council on Physical Medicine has authorized publication of the following article. HOWARD A. CARTER, *Secretary.*

THE USE OF X-RAYS FOR THE TREATMENT OF HYPERTRICHOSIS IS DANGEROUS

ANTHONY C. CIPOLLARO, M.D.
New York
and
MARCUS B. EINHORN, M.D.
Albany, N. Y.

Dermatologists, radiologists, physicists and others administering roentgen therapy for any purpose are well aware of the immediate dangers to the skin and the long range sequelae of this type of treatment. Soon after the discovery of x-rays by Roentgen in 1895 their application to the treatment of diseases of the skin was carefully studied and their effects noted. The x-rays were found to benefit many dermatoses and by 1897, their epilating effect having become known, they were used for the treatment of superfluous hair. Many investigators were studying the beneficial effects of roentgen rays on diseased tissue, while other research workers were studying their harmful effects on normal tissue. They soon learned that single large doses or repeated small doses over a long period of time were dangerous. They discovered that the effects of repeated small doses were cumulative and produced destruction of tissue many years after their administration. Sequelae were known to appear in the form of pigmentation, depigmentation, telangiectasia, wrinkling, atrophy, keratoses, ulceration and finally carcinoma. These facts were constantly stressed and reported in the literature by the pioneers working with roentgen rays and radium.

Matas[1] reported x-ray sequelae which appeared years after treatment, emphasizing the delayed appearance of x-ray burns after long periods of latency. Porter[2] in 1909 reported 47 cases of skin injuries due to roentgen rays with 41 of these resulting in cancer. In 1922 he again wrote a paper on roentgen ray sequelae, reporting 107 cases, in which he described harmful lesions occurring as the result of a single massive dose or repeated small doses of roentgen rays.

Wolbach[3] stressed the fact that malignant changes are not sudden but take place after a period of years.

---

[3] Wolbach, S. B.: A Summary of the Effects of Repeated Roentgen Ray Exposures on the Human Skin Antecedent to the Formation of Carcinoma, Am. J. Roentgenol. **13:** 139 (Feb.) 1925.

MacKee and Cipollaro,[4] Stout,[5] Pfahler[6] and many other investigators confirmed these findings. MacKee and Cipollaro[7] reported that malignant disease developed in an estimated 25 per cent of patients with radiodermatitis, especially in those in whom there had been such sequelae as keratoses, sclerosis and ulcerations. These cancers were usually of the squamous cell type, although sarcomas, basal cell epitheliomas and bowenoid lesions have also been reported.

The fact that roentgen rays could produce permanent alopecia was well known then as it is today. It was found that the large dose necessary to produce epilation could also cause the destruction of all cellular structures about the hair follicles, could burn the skin and bring about atrophy, wrinkling, telangiectasia, keratoses and sooner or later could cause cancer or other malignant diseases, which in some instances caused death. Then, as now, experience showed that roentgen rays and all other ionizing radiations are so insidious that cancer of the metastasizing type might occur months or years after their application. These undesirable late effects occurred after a single treatment or after multiple treatments administered during several days or weeks. Dermatologists and radiologists have been aware for years of the dangers of treating hypertrichosis with x-rays, dangers unnecessary because this condition is only a cosmetic defect and is amenable to safe methods of treatment.

But while the members of the medical profession, on the one hand, frowned on the treatment of hypertrichosis with radiation therapy, lay groups on the other hand were springing up to treat unwanted hair by roentgen ray methods for profit. Because it was found to be a lucrative business, catering especially to in women who wanted hair removed permanently d painlessly from the face, legs, thighs, breasts and ven from the pubic and perianal areas, quacks and charlatans, individually or in unscrupulous institutes, groups, organizations and systems, began operating throughout the country. Some of these quacks were aware of the dangers of x-rays but were unconcerned about the long range results of their use. The names of the treatments were the "Tricho System," "Short Wave Treatment," "Epilax Ray," "Light Treatment" and other terms which did not disclose the nature of the treatment.

Perhaps the most widely publicized and largest organizations engaged in the business of treating hypertrichosis with x-rays was the "Tricho Institute." It is believed that Albert C. Geyser, M.D., a New York physician, was the founder of this institute in the early 1920's. He claimed to have perfected the x-ray treatment so that he had a harmless method of removing superfluous hair. In order not to mention x-rays, he called his method the "Tricho System." He leased machines for the production of roentgen rays to beauty parlors and, in addition, gave a two week course to the beautician who was to operate the machine. After this short period of instruction in theory and clinical practice, the graduate was, according to Geyser standards, qualified to operate according to the Tricho System.

The average dose was approximately one-half skin unit.[8] The treatments were given every two weeks and the hair was shed by the sixth treatment. After the loss of hair, more treatments were administered so that the alopecia would be permanent. Dr. Geyser claimed that this procedure caused functional interference with and gradual atrophy of the hair papillae.

It was evident that Dr. Geyser[9] knew what might happen if these x-ray machines were allowed to fall into the hands of inexperienced operators. In 1925 he delivered an address at the Chicago meeting of the American Association for Medico-Physical Research on the "Truth and Fallacy Concerning the Roentgen Ray in Hypertrichosis." In this address he spoke plainly of the dangers of roentgen ray doses sufficient to produce permanent epilation but protected himself by stating that his method was quite safe because he used homeopathic doses with filtration administered over a long period of time. Dr. Geyser later claimed to have seen over 25,000 areas cleared of superfluous hair in a period of ten years. His system flourished, with branches in many cities over the entire United States and in Canada.

As the years passed, cases of radiodermatitis, horrible burns, painful ulcerations and cancer resulting from the Tricho System of treatment were observed by dermatologists and other physicians in all sections of the country. The dangers and sequelae that were stressed by the pioneers were now made manifest years after the treatment had been ended. The so-called harmless rays, administered by inexperienced operators for large financial returns, had left their imprints. These ranged through pigmentation, depigmentation, telangiectasia, atrophy, wrinkling, keratoses, ulceration, cancer and death. Even sarcoma can be the result of the Tricho treatment. Kaplan[10] reported a case of sarcoma developing in an area of radiodermatitis following the removal of superfluous hair by the Tricho Institute. Judging from conversations with dermatologists in different sections of the country and judging from the many cases of radiodermatitis seen in practice and in clinics, the number of cases of x-ray burns, cancer and death resulting from treatments administered by the Tricho Institute must have run into the thousands. It is impossible to obtain or estimate the actual number because the cases were not reportable and therefore were not recorded.

In 1929, at the eightieth annual session of the American Medical Association, a resolution was passed that all roentgen ray burns due to the treatment of hypertrichosis by the Tricho System and allied systems be reported to the Bureau of Investigation[11] and that these methods of treatment be condemned as highly dangerous to the patient. Many dermatologists and other physicians cooperated in this investigation. These case reports were published in THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION[12] Jan. 19, 1929 in abstract form. The A. M. A. Bureau of Investigation had reprints made of the article, with additions. So vital is this subject at the present time that this reprint is given in full:

Prepared and Issued by the Bureau of Investigation of the American Medical Association in October 1930.—

THE TRICHO SYSTEM

The Albert C. Geyser X-Ray Method of Depilation

Quoting from the opening paragraph of the advertising booklets distributed by "beauty parlors" that use the method: "Tricho System is the invention of Albert C. Geyser, M.D., a New York physician internationally famous as a specialist on Electro-Therapy."

Dr. Geyser claimed to have so modied the x-rays that with his apparatus it was possible to produce permanent baldness in hairy areas without any possibility of doing any damage to the skin. He called his device not an x-ray machine but a "Tricho System." In New York City, where the law requires that x-ray operators must be licensed and shall operate only under a permit, Dr. Geyser made application for a permit, which was issued, as Dr. Geyser is a legally licensed practitioner of medicine. This fact was taken advantage of in the advertising material of the Tricho concern, where this statement appeared:

> "The machine also has been examined for the Division of Institutional Inspection of the Board of Health of the city of New York and pronounced—SAFE."

While this statement was technically true, it was grossly misleading to the public, for the public might naturally assume that the word "safe" refers to the therapeutic effects rather than the mere physical equipment.

The Tricho Sales Corporation leased the Geyser machines to "beauty parlors" and the machines are scattered across the country from the Atlantic to the Pacific, the northern boundary to the Gulf.

It is not necessary to tell physicians—at least, those with any extensive dermatologic experience—how serious a menace is the use of the x-rays in the removal of superfluous hair. The tragedy in the case arises from the fact that the precancerous keratoses and other untoward effects are usually not evident for months after the "treatment" has been given. There is the further unfortunate factor in the problem that the victims—nearly always women—frequently refuse to prosecute, because of the inevitable publicity. A few dermatologists have, however, reported cases to The Journal of the disfiguring and dangerous sequelae that have followed the use of the Tricho System.

A brief abstract of the histories of some of the cases that have been reported to The Journal follows:

Miss E. W. (aged 31), Boston.—Tricho treatments from 1924 to the spring of 1927. Beginning telangiectasia on each side of the face and chin, with subcutaneous redness and dry skin. (Reported by Dr. Arthur M. Greenwood.)

Mrs. C. F. B. (aged 42), Boston.—Numerous Tricho treatments, last one July 1927. Lip and chin dry and wrinkled, with area of whitish atrophy and blotches of redness; nodule on right side with sluggish, necrotic center. (Reported by Dr. Arthur M. Greenwood.)

Mrs. R. H. M. (aged 53), Boston.—Twenty-six Tricho treatments, commencing June 1925. Skin of cheeks red, slightly thickened, with scaly patches, considerable itching, skin dry and two crusted pigmented lesions on neck, with scattered telangiectases. (Reported by Dr. C. Guy Lane.)

Mrs. C. J. E., Boston.—Twenty-five Tricho treatments, commencing in 1925. Skin of cheek dry, thick, pigmented, with a few scattered telangiectases. Two areas of chronic radiodermatitis on each side of the neck, with increased pigmentation, atrophy and telangiectases. (Reported by Dr. C. Guy Lane.)

Mr. I. L. (aged 35), Boston.—Fifteen Tricho treatments, last one in February 1926, for excessive hairiness of the neck. Extensive areas of telangiectasia, with atrophy, extending over neck and on to cheeks. (Reported by Dr. C. Guy Lane.)

Miss A. M. (aged 35), Boston.—Fourteen Tricho treatments of hands in 1926. In 1928 small red spots over backs of both hands and fingers, marked telangiectases and slight thinning. (Reported by Dr. C. Guy Lane.)

Miss B. F.—Twenty-five Tricho treatments on face and forearms four years previously. Atrophy and telangiectasis on both face and forearms. (Reported by Dr. J. H. Swartz.)

Miss B.—Tricho treatments to face. Atrophy, telangiectasis and ulceration. (Reported by Dr. J. H. Swartz.)

Mrs. A. E. C. (aged 32), Boston.—Fifteen Tricho treatments five years previously. Red blotches, with areas of telangiectasis and atrophy on chin. (Reported by Dr. C. Guy Lane.)

Mrs. R. C. (aged 50), Boston.—From thirty to forty Tricho treatments, the last one two years previously. Red spots on left side of chin, with stinging sensation, telangiectasia and atrophy. (Reported by Dr. C. Guy Lane.)

Mrs. H. S. (aged 36), Boston.—Tricho treatments five years previously. Red blotches on cheeks and under chin, with marked atrophy and extensive telangiectasia. (Reported by Dr. C. Guy Lane.)

Miss M. H. (aged 23), New York.—Tricho treatments four years previously for hairiness of cheeks and chin. Moderately severe telangiectasia of both cheeks and chin. (Reported by Dr. Howard Fox.)

Miss M. S. (aged 25), New York.—Two years' Tricho treatments, about twenty-five in all. Telangiectases of both cheeks and beneath the jaw; some of the superfluous hair still remains. (Reported by Dr. Howard Fox.)

Mrs. L. (aged 38), New York.—Tricho treatments in 1924 for hairiness of the legs. Red burning areas developed, became crusted and then turned "dead white." Application of iodine to a mosquito bite in one of the white scars followed by persistent ulceration. (Reported by Dr. Howard Fox.)

Mrs. B. (aged 25), New York.—Tricho treatments for one year, ending August 1924, for hairiness of chin and neck. Telangiectasia appeared one year later, gradually increasing to involve lower jaw, chin and neck. (Reported by Dr. Howard Fox.)

Mr. H. E. (aged 31), New York.—Consulted Albert C. Geyser in spring of 1923 for hairiness of the trunk. Treated at that time and also a year later. X-ray burn, with telangiectasia, over entire chest, upper abdomen and back, with pigmentation, atrophic white spots and crusts. (Reported by Dr. Howard Fox.)

Miss E. E. (aged 32), New York.—Fifteen to eighteen Tricho treatments in 1926 and 1927. Telangiectasia of both forearms, with slight atrophy of the skin; much of the hair has returned. (Reported by Dr. Howard Fox.)

Mrs. I. K. (aged 37), New York.—Fifteen Tricho treatments for hairiness of face and arms in 1924. A year later, telangiectases appeared; now profuse on both arms and moderate amount on cheeks and chin. (Reported by Dr. Howard Fox.)

Mrs. A. C. P., Connecticut.—Twenty Tricho treatments. Red spots developed over treated areas, skin wrinkled, cheeks, neck and upper lip showed telangiectases, pigment destroyed and marked wrinkling, due to atrophy. (Reported by Dr. Joseph Gardner Hopkins.)

Miss R. H., New York City.—Eight months' Tricho treatment for hairiness of chin and forearms. Two years later, skin of chin wrinkled, white and covered with a fine down. Below chin two deep red, oval patches of telangiectases; tufts of dilated veins forming dark red points on forearms. (Reported by Dr. Joseph Gardner Hopkins.)

Miss B. G. (aged 24), Boston.—Two years after taking Tricho treatments for excessive hair on the chest, telangiectasia became evident, with atrophy. (Reported by Dr. Austin W. Cheever.)

Miss M. R. (aged 29), Brooklyn.—Tricho treatments for several months. Wrinkling of skin about chin and cheeks, with numerous patches of telangiectasia. (Reported by Dr. Joseph J. Eller.)

Miss R. V. (aged 22), Brooklyn.—Twenty treatments by Albert Geyser. X-ray burn of chin and neck region, with wrinkling and telangiectasia. (Reported by Dr. Joseph J. Eller.)

Miss S. T., St. Louis.—Twenty-three Tricho treatments of cheeks and neck. Dry dermatitis of the area, with wrinkling, atrophy and scattered telangiectasia. (Reported by Dr. G. V. Stryker.)

Miss S. T., New York.—Tricho treatments three years previously. Marked telangiectasia of the chin and neck, commencing two years after treatment and getting steadily worse; also some atrophy. Still considerable hair in the area involved. (Reported by Dr. George Miller MacKee.)

Miss S. R., New York.—Twenty Tricho treatments three years previously. Telangiectasia and atrophy both present and growing steadily worse. Painful ulcer as large as a silver dollar over left jaw. (Reported by Dr. George Miller MacKee.)

Miss E. T., New York.—Tricho treatments six years previously for hairiness of the face. Atrophy developed four years later. Patches of telangiectasia, pigmentation and depigmentation, with wrinkling; also a scleroderma with keratotic surface. Still considerable coarse dark hair over area treated. (Reported by Dr. George Miller MacKee.)

Mrs. E. F. (aged 30), Washington, D. C.—About thirty Tricho treatments for hairiness of legs in 1927. Extensive telangiectasia and beginning atrophy over entire outer surface of both legs from hips down. (Reported by Dr. F. J. Eichenlaub.)

Miss C. R. M. (aged 28), Washington, D. C.—Twenty-four Tricho treatments in 1926. Both cheeks and chin show marked atrophy, wrinkling of the skin, with telangiectasia; over angle of one jaw an ulcer, suspicious of beginning cancer. (Reported by Dr. F. J. Eichenlaub.)

Miss M. S. (aged 27), Washington, D. C.—Large number of Tricho treatments in 1924. Chin shows well-marked x-ray burns, with wrinkling, atrophy and telangiectasia. (Reported by Dr. F. J. Eichenlaub.)

Mrs. E. B. (aged 30), Washington, D. C.—Number of Tricho treatments in 1926. Cheeks and chin show marked wrinkling and some atrophy; still some hair present. So depressed about disfigurement that she attempted suicide. (Reported by Dr. F. J. Eichenlaub.)

Miss M. W. (aged 28), St. Louis.—Tricho treatments two years previously for hairiness of arms. Multiple marked telangiectases of both forearms and lower portion of arms; entire area mottled. (Reported by Dr. Erich Brockelmann.)

Mrs. W. S., Buffalo, N. Y.—Tricho treatments in 1927 and 1928 for hairiness of chin, neck and cheeks. Shows mild degree of atrophy and telangiectasia over area treated. (Reported by Dr. Earl D. Osborne.)

Miss H. B., Buffalo, N. Y.—Ten Tricho treatments for hairiness of neck, face, forehead and lip in 1927 and 1928. In May 1929, moderate degree of atrophy, telangiectasia and facial disfigurement. (Reported by Dr. Earl D. Osborne.)

Mrs. F. G., Buffalo, N. Y.—Tricho treatments in 1925, 1926 and 1927 for hairiness of cheeks and chin. In September 1928, moderate degree of atrophy, telangiectasia, mottled pigmentation and facial disfigurement. (Reported by Dr. Earl D. Osborne.)

Mrs. J. W. (aged 49), Detroit.—Tricho treatments in the summer of 1927. In spring of 1929, an ulcer over the angle of the right jaw, cheeks and neck, covered with telangiectases, keratoses and atrophy. Numerous long hairs in the atrophic skin. (Reported by Dr. Rollin H. Stevens.)

Mrs. A. W., Detroit.—Several Tricho treatments five years previously. Red and white spots on the skin of the face, with atrophy and telangiectases; several hairs still present. (Reported by Dr. Rollin H. Stevens.)

Mrs. H. J. P. (aged 29), Detroit.—Reported several Tricho treatments five years previously. Two or three years later patient noticed red marks and atrophic areas. This gradually spread, so that in May 1930 there was atrophy and telangiectases of the cheek, neck and chin. (Reported by Dr. Rollin H. Stevens.)

Miss D. M. (aged 26), Washington, D. C.—Took Tricho treatment for superfluous hair on hands, forearms, axilla, chin and outer portion of right lip. Developed numerous telangiectases of the hands and arms, atrophy and telangiectasis in both axillae, wrinkling of the skin of the chin, with atrophy and telangiectasis of the upper lip; also marked atrophy of the gum beneath the lower lip. (Reported by Dr. H. H. Hazen.)

Mrs. A (aged 38), Washington, D. C.—Developed marked wrinkling of cheeks and chin and numerous telangiectases over this area, following Tricho treatment. (Reported by Dr. H. H. Hazen.)

Miss H. (aged 28), Washington, D. C.—Developed wrinkling and large blotchy telangiectases beneath the chin, with considerable atrophy and retraction of gums of both upper and lower jaws, following the Tricho treatment. (Reported by Dr. H. H. Hazen.)

Mrs. P. (aged 32), Washington, D. C.—Eighteen months after Tricho treatment, developed numerous telangiectases of forearms and of legs from knee to ankle, with marked atrophy of the skin of both legs. (Reported by Dr. H. H. Hazen.)

Mrs. G. (aged 35), Washington, D. C.—Developed wrinkling of the eeks and chin and numerous blotchy, purplish telangiectases of the same ca, together with marked retraction of both upper and lower gums, ollowing the Tricho treatment. (Reported by Dr. H. H. Hazen.)

Mrs. Z. (aged 55), Washington, D. C.—Following Tricho treatment, developed telangiectasis of the cheeks and chin, with marked wrinkling. There was also considerable retraction of the gums. (Reported by Dr. H. H. Hazen.)

Miss S. (aged 32), Washington, D. C.—Developed marked wrinkling and telangiectasia of cheeks and chin, following Tricho treatment. (Reported by Dr. H. H. Hazen.)

Mrs. B. (aged 43), Washington, D. C.—Year after Tricho treatment, developed wrinkles and atrophy over entire cheeks and chin; also retraction of the gums in both upper and lower jaws. (Reported by Dr. H. H. Hazen.)

Miss M. (aged 30), Washington, D. C.—Following Tricho treatment, developed telangiectasis of the forearms and both sides of the legs from knee to ankle. Beneath the calf of the left leg, a depression two inches in diameter, nearly one-half inch in depth, with the surrounding skin for an area of nearly an inch stony-hard and immobile. Cheeks and chin showed numerous telangiectases and characteristic wrinkling and gums were markedly atrophied and retracted. (Reported by Dr. H. H. Hazen.)

Mrs. S. (aged 50), Washington, D. C.—Received about thirty Tricho treatments, the last one about three years ago. Face shows numerous telangiectases and some atrophy. (Reported by Dr. H. H. Hazen.)

Miss S. (aged 30), Washington, D. C.—Took twenty or twenty-five Tricho treatments, the last one two years ago. Anterior portion of cheeks and chin show marked wrinkling and numerous telangiectases, also some retraction of the gums. One feature of this case is the large number of small pits, resembling smallpox scars. (Reported by Dr. H. H. Hazen.)

Miss W. (aged 25), Washington, D. C.—Had about eighteen Tricho treatments, the last two years ago. Has developed pale telangiectases over anterior portion of cheeks and chin, with some wrinkling. Still has considerable superfluous hair left. (Reported by Dr. H. H. Hazen.)

Miss H. K. (aged 30), Milwaukee.—Fifteen Tricho treatments between July 1926 and April 1927. Treatments resumed and four exposures given between July 1 and September 11, 1927. In October 1927, patient first observed redness and pruritus, which increased in severity, resulting in painful ulceration and disability. In December 1928, hands and forearms showed cutaneous atrophy, telangiectasia and pigmentation, while both legs showed extensive injury from the knees to the feet, with telangiectasia, atrophy and pigmentation. A deep x-ray ulcer below the right knee; smaller ulcers below the left knee and a number of atrophic adherent scars of previously healed ulcers. Patient wholly disabled for work, bedridden, and suffering severely. (Reported by Dr. Harry R. Foerster.)

Mrs. I. C. (aged 27), Milwaukee.—Reported taking about ten Tricho treatments in 1925 in Bridgeport, Conn., for hairiness of thighs and legs. Some two years after exposure, telangiectasia first observed, steadily increased in severity, and involved skin became tender and at times painful. In January 1930, examination showed large angular patches of cutaneous atrophy and telangiectasia on the thighs and calves; hair growth persisted. (Reported by Dr. Harry R. Foerster.)

Miss E. M. (aged 20), Milwaukee.—Took Tricho treatments in Milwaukee in 1927 for hairiness of the face and chest. Reported twelve treatments to the face and sixteen to the chest, over a period of a year. In April 1929, there was cutaneous atrophy and telangiectasia between the breasts and on the lower part of the chest, and cutaneous atrophy and telangiectasia, with some hairiness persisting, on both lips and chin. (Reported by Dr. Harry R. Foerster.)

Mrs. S. H. D. (aged 44), Milwaukee.—Took Tricho treatment for hairiness of the chin. In September 1929, extensive telangiectasia and atrophy in the treated area. (Reported by Dr. Harry R. Foerster.)

Mrs. A. R. (aged 55), Milwaukee.—Received sixteen Tricho treatments, the last one in December 1928. In March 1930, telangiectasia, atrophy and fine hair growth in the treated areas of the face. (Reported by Dr. Harry R. Foerster.)

Mrs. E. F. M. (aged 26), Milwaukee.—Received ten Tricho treatments at weekly intervals, and then one treatment for three months between January 1927 and June 1930. Examination showed slight cutaneous atrophy and mild telangiectasia; coarse hair still present. (Reported by Dr. Harry R. Foerster.)

The brief case histories just given do not square with the statement made by Dr. Albert C. Geyser, that the production of keratoses is "physically and physiologically impossible with the Tricho System." Dr. Geyser has also declared: "The very fact that these machines are installed in beauty parlors and that the beauty parlor public is a hypercritical public, is prima facie evidence that this system of treatment is eminently satisfactory." It would be interesting to know just how many suits for damages have been brought by those who have undergone the Tricho treatment to find, later, to their sorrow that, in their endeavor to remove a minor blemish, they have incurred a major injury.

In glancing over the literature we discovered a few more cases, and brief abstracts of these are presented:

M. C., a woman aged 35, New York.—Tricho treatments for twenty-five weeks for hypertrichosis six years previously. Two years later, profuse and disfiguring telangiectasia developed beneath the chin and right cheek. (Reported by Dr. Howard Fox.[13])

White woman aged 24, Chicago.—Treated five years previously for superfluous hair on legs and arms by the Tricho system. The patient had two treatments a week for one year. Sclerodermatous areas, telangiectasia and ulceration resulted. (Reported by Dr. Edward A. Oliver.[14])

J. P., a white woman aged 22, St. Louis.—Superfluous hair on face removed by Tricho method three years previously. The patient presented dryness of skin on chin, atrophy and telangiectasia. (Reported by Dr. Clinton W. Lane.[15])

Miss H. T., New York.—Tricho treatments eight years previously. The patient had three treatments a week for one year for mild hypertrichosis of the chin and cheeks. Two years later atrophy and telangiectasia developed. The superfluous hair still present on the chin. (Reported by Dr. Henry Silver.[16])

J. N., a woman aged 28, New York.—Twenty treatments eight years previously for excessive growth of black hair on face. Six years later telangiectasia, scarring and a strawberry red tumor mass developed on right cheek. The mass was diagnosed as a spindle cell sarcoma. (Reported by Dr. Ira I. Kaplan.[17])

L. S., a woman aged 46, New York.—Fifteen years previously a course of Tricho treatments was given for excessive hair on both cheeks. Leathery skin, telangiectasia, ulcerations, and squamous-celled epithelioma developed. Histologic examination confirmed the diagnosis. (Reported by Dr. Ira I. Kaplan.[18])

Within the past several weeks there appeared at the office of the senior author 4 Tricho patients:

1. E. B., a woman school teacher who had over fifty Tricho treatments about twenty-two years ago on the face, breasts, arms, legs and abdomen. There were all the classic signs of late radiodermatitis, including keratoses and epitheliomas. The patient has had several plastic operations, some quite extensive.

2. C. B., a housewife, had numerous Tricho treatments about twenty-four years ago on the face. Now she has typical radiation sequelae. On the right cheek there are a keratosis and changes associated with an early epithelioma.

3. M. T., a public health nurse, was treated about twenty-five years ago at the Tricho Institute in New York for the removal of hair from the face. There developed the typical conditions of radiodermatitis, particularly severe in the submental and submaxillary regions, where the sclerotic areas were constantly breaking down, forming small ulcerated areas. About one year ago she had a plastic operation.

4. T. C., a woman librarian, had received numerous treatments about twenty years ago at the Tricho Institute for removal of unwanted hair of the face, arms, legs, thighs and buttock. When seen fifteen years ago she had such painful ulcerations of the anterior and posterior surfaces of both thighs that she would be awakened screaming in the middle of the night. Plastic operations were performed immediately

These abstracts are representative of the cases which physicians have reported; no doubt there are many thousands of cases which have not been recorded. However, one need only glance over these cases to realize how dangerous roentgen rays can be when they are administered by inexperienced people for the permanent removal of hair. In fact, no method which includes the use of roentgen rays for the treatment of hypertrichosis should be approved, because, as MacKee and Cipollaro [4] have said, "it is now the consensus of dermatologists and roentgenologists that superfluous hair cannot be permanently removed with radiation of any kind, regardless of technic, without permanent injury to the skin." In another book by MacKee and Cipollaro [7] there is a photograph (fig. 84) on page 71 which illustrates the development of a squamous cell carcinoma in a patient who had received an x-ray burn during treatment at the Tricho Institute. In Dr. Kaplan's book [10] there is a photograph (fig. 196) on page 513 of a woman with a spindle cell sarcoma developing on an x-ray burn. This is another Tricho patient. She died as a result of the malignant disease. Is any more evidence necessary to prove that roentgen rays or other ionizing agents used for the permanent removal of hair are dangerous, cause radiodermatitis and, later, cancer and death?

A new monster is now lurking around the corner. It is because of this present and future danger that we have prepared this article, not because it is enjoyable to repeat the horror stories of the past which arose from the improper use of x-rays. The harm that was done to girls and young women in the twenties is about to be repeated now in the forties and fifties. It is hoped that the danger can be forestalled and girls and young women can be saved from the agonizing pain suffered by their sisters two decades ago. One can foresee that even boys and young men may be subjected to the same danger, because a patent has been issued for the "X-Ray Razor."

During 1946 there appeared articles in newspapers and magazines pertaining to the X-Ray Razor. The United States Patent Office on Nov. 20, 1943 issued to Violet Arnold, Detroit, patent number 2,389,403 for this method and apparatus for removing hair from the human body. The apparatus described in the patent is a low voltage (60-70 kv.) lightly filtered (0.5 to 1.0 mm. of aluminum) x-ray apparatus. One filter described in the patent consists of two laminated sheets of aluminum each 0.5 mm. in thickness with a space between them of 1 mm. for the purpose of holding water. The x-rays pass through this water and aluminum filter. To radiologists and to dermatologists there is nothing new either in the apparatus or in the method. The patent states that the object of the invention is to provide a treatment for the removal of hair from the human body without injury to the body tissue. Every experienced physician knows that this is impossible and that if the apparatus and method described in the patent are used there will be a repetition of the disastrous conditions experienced with the Tricho method. The immediate results of radiotherapy for hypertrichosis are always good. It takes months or years for radiodermatitis to develop, and it takes even longer for the keratoses, ulcerations, malignant growths and death to occur. It is to be hoped that the manufacturers of x-ray apparatus in this country will not produce equipment to sell to those endangering the health of American people with x-ray burns and cancer. It also behooves every physician in the country to be alert to this rebirth of the Tricho System, and it might be advisable to learn how this patent can be rescinded.

The Council on Physical Medicine has information that in Chicago there is a firm called the Keat Corporation which advertises a method of removing hair by "a simple light treatment." Presumably the same corporation is in business in Detroit and Des Moines and is contemplating opening offices elsewhere. Representatives of the American Medical Association, requesting information by mail and visiting the Keat Corporation, were unable to get definite information about the treatment. One young man who was treated by the Keat Corporation was examined by a Chicago physician, and it was found that the treatments administered did cause epilation of the bearded area. The only radiations that can cause epilation are ionizing radiations, and the meager information obtained by the American Medical Association representatives leads one to believe that the apparatus was an x-ray machine. The Keat Corporation, if allowed to grow, may cause even more damage than the defunct Tricho Institute. The local health authorities, the chambers of commerce, the Better Business Bureau, the legislative committees and all civic organizations concerned with the guarding of the health of the public should join forces and nip in the bud the spread of organizations using x-rays for the permanent removal of unwanted hair.

The members of the medical profession need to guard against still another possible health hazard. Radioactive isotopes emitting beta and gamma rays could be used for the local treatment of skin diseases. Some one might conceive the idea of applying to hairy parts solutions or other preparations of radioactive isotopes with the erroneous thought that these ionizing agents might have selective actions. There is no question whatever in the minds of physicians that radioactive isotopes can cause permanent defluvium of the hair but at the same time can so damage the skin that all the changes associated with a radiodermatitis, including the malignant changes, will be manifested. This is written not with the idea of predicting the use of radioactive isotopes for the treatment of hypertrichosis but with the idea of cautioning against the use of atomic energy for such treatment.

STUDY OF MOTOR VEHICLE FATALITIES

A special report on motor vehicle accident fatalities, just released by the National Office of Vital Statistics of the U. S. Public Health Service, considers data obtained by the Traffic Authority of the reporting states and from the death certificates filed in the Bureau of Statistics. This report for 1945 shows the number of such deaths that occur in hospitals and the duration of injuries prior to death, the types of fatal motor accidents, where they occurred, the residence of the victims and their age, sex and race. The states that provided this data included about 82 per cent of the opulation of the United States. The number of deaths orted on the special motor vehicle death transcript resented 81 per cent of motor vehicle accident deaths registered in the United States in 1945.

The largest number of accidents that caused deaths occurred in the late fall and early winter, more than one third of the fatalities resulting from accidents that occurred in October, November and December. More deaths resulted from accidents that occurred on Saturday than on any other day of the week. The curve of fatalities in rural areas followed the curve for miles of travel on rural roads for the first seven months of 1945, but this curve did not decrease with the decrease in travel in the last three or four months of the year. If inclement weather caused the divergence of the mileage curve and the death curves in the last third of the year, it is difficult to explain why January and February were not marked by comparatively large numbers of deaths. While in 1945 the rise in deaths began in August, the month in which gasoline was not rationed, and continued in each subsequent month, the mileage remained almost unchanged from August to December. The largest number of fatalities occurred between 6 p. m. and 7 p. m. The whole period from 5 p. m. to 9 p. m. was more hazardous than other similar parts of the day.

Collisions with pedestrians accounted for the largest number of fatalities, 39.5 per cent of the total. Collisions between motor vehicles accounted for 25.7 per cent of the total deaths for which the type of accident was stated. In 1941 each of these two types of accidents accounted for one third of the fatalities. The percentage of pedestrian fatalities for 1945 was an increase over that of 1941, while the percentage of collisions between motor vehicles represented a decrease. Passenger deaths accounted for 30.1 per cent and deaths of drivers for 28.5 per cent. Accidents which occurred on side streets or in residential areas, so-called nontraffic deaths, caused 141 deaths, most of which were in children 1 to 4 years of age. Beyond 19 years of age, in the majority of instances, the fatal nontraffic motor accidents occurred in an industrial area.

Health officers and administrators, traffic and safety engineers as well as others may gain information from this study that will help them devise means to prevent some of the thousands of motor vehicle deaths that occur in this country each year. Strict measures should be invoked particularly against accidents on industrial property and on home premises, the latter to be directed especially toward saving the lives of preschool children.

THE CLEVELAND INTERIM SESSION

By action of the House of Delegates the supplemental session of the American Medical Association, Cleveland, Jan. 5-8, 1948, will include not only the technical and scientific exhibits, which have come to be among the most important features of the Annual Session, but also a program of papers designed particularly as postgraduate education for general practitioners. The Council on Scientific Assembly, with Dr. Henry R. Viets of Boston as chairman, has prepared a program covering many of the topics now most prominently before the members of the medical profession.

The first morning's program will include papers on peptic ulcer, blood dyscrasias and the chronic invalid, with a panel discussion on posthospital care of patients with cancer. The program for the afternoon provides discussions on the treatment of the fat and the lean, cancer of the prostate and the use of BCG vaccine in the prevention of tuberculosis, with a panel discussion on uterine hemorrhage. At each of the panel discussions there will be ample opportunity for questions and answers.

The program for the second morning of the general practitioners' session will begin with a symposium on multiple injuries in automobile accidents, followed by a panel discussion on the treatment of pathologic conditions in adolescence. In the afternoon there is to be a panel discussion on the treatment of the healthy and sick diabetic patient, followed by papers on jaundice, the Rh factor and the interpretation of roentgen ray films of the chest.

Within the next few weeks The Journal will publish the details of this program, including the names of the distinguished medical educators and clinicians who will participate.

During the first two days of the session, when the House of Delegates will be holding its meetings, the Council on Industrial Health of the American Medical Association will be conducting a program devoted particularly to problems in its field. The complete program will be published soon.

Among the features planned for the Scientific Exhibit is a demonstration of the operation of a diagnostic cancer clinic, in which visiting physicians will be given opportunity to undergo themselves the routine of such an examination.

Another feature of the interim session in Cleveland will be the awarding for the first time of a gold medal to a general practitioner who has rendered exceptional service to his community. In these times, when almost everyone in the field of medicine recognizes the importance of the general practitioner in our medical scheme and the necessity that he be kept abreast of current progress, the Cleveland session should attract great numbers of the leading general practitioners of the United States..

THE AMERICAN LEGION CONSIDERS MEDICAL CARE

The following recommendations made by the National Medical Advisory Board of the American Legion were adopted by the National Convention of the American Legion held in New York, August 28-31:

1. That a suitable resolution be prepared by the National Rehabilitation Committee and submitted to the National Convention for their approval requiring the appointment or election of a Department Medical Advisor in every Department and a Post Medical Advisor in every Post, both to be doctors of medicine.

2. The establishment of an "American Legion Medical Forum of the Air," in cooperation with the national public relations division of the American Legion.

3. To the National Commander and to the Rehabilitation Executive Committee that the American Legion favors medical research in all its phases.

4. Continued effort to promote and enhance the American Legion's and American Legion Auxiliary's program on rheumatic fever and rheumatic heart disease and its volunteer cooperative effort with the American Council on Rheumatic Fever of the American Heart Association. The American Legion's action has already been productive of a well organized national program in rheumatic fever and rheumatic heart disease by the American Council on Rheumatic Fever of the American Heart Association.

5. That we approve of the residency program and the Dean's Committee as set up throughout the nation by the Veterans Administration and further recommend its extension to Veterans Administration outpatient clinics. We believe that this approach assures the veteran the best medical care possible. That the outpatient service, though good in many respects, should be improved and strengthened on a sound and lasting basis.

Adequate outpatient medical service should be made to meet the needs of the vast majority of sick veterans. In fact, in many instances this service is more important to the veteran than that obtained in hospitals. Improvement in the outpatient clinic is, in our opinion, a great factor in the reduction of the need for the hospitalization of the veterans who may need such treatment.

We believe consideration should be given by the Veterans Administration to the adoption of an intern service in the hospitals where it is appropriate and to the possibility of introducing clinical clerkships in the teaching hospitals and these to be under the direction of the resident staff members and the supervision of the Dean's Committee.

Since diagnosis and home treatment is the essence of clinical service, the residency program should involve training of all residents in the work of outpatient clinics.

Whereas the medical and surgical staffs of Veterans Administration hospitals will shortly be depleted by the loss of temporary assignments of military personnel, therefore, it is the recommendation of the Board that the Congress be petitioned to enact adequate legislation to permit internships in veterans hospitals.

6. That while we believe that the Veterans Administration hospital care, especially in larger hospitals, has improved and is in fine condition, yet we urge constant effort to keep that service at its highest efficiency.

7. The Board is cognizant from the reports of the Veterans Administration of the abuses that have occurred under the methods inaugurated by them in their endeavor to obtain the maximum amount of medical and dental care for the veteran under the home-town program in the time when the need is most pressing. However, it is now felt that many of these conditions that seem to be out of proportion to the situation as it now exists could be eliminated by a careful study by the medical and dental groups within the state which executed a contract for this service. In a project of such great magnitude abuses are bound to occur. Where evidence of such abuses is apparent, it is recommended that they be called to the attention of the licensing board in the state where they occur, and that a copy of this be submitted to the local county society concerned.

8. That in the treatment of veterans, it is a time proven fact that veterans in the professions understand and are peculiarly equipped to treat veteran patients because of their understanding born of their actual and common experience, and we therefore recommend that all members of the medical and dental professions who are veterans be given first consideration in the appointment and training under any program inaugurated by the Veterans Administration. The Board, however, realizes that the tremendous task of the care and treatment of veterans requires a greater number than the actual number of available veterans in these professions. Veterans preference should hold, however, for physicians, dentists and nurses, all other things being equal.

9. It is recommended to the Congress of the United States that when economy is to be practiced in the nation it should not be at the expense of the health of the veterans who saved the nation.

These recommendations are so important in relation to the policies and principles of the members of the American medical profession that they should be given most careful consideration by every physician.

Attention is called particularly to the third recommendation, which favors medical research in all its phases. The American Legion has developed a program on rheumatic fever and rheumatic heart disease and now has determined officially to continue this work and to enhance it. The support of the American Legion for the association of medical care in the Veterans Administration with medical teaching is a most progressive step, and it is recognized that the medical care program of the Veterans Administration is in process of evolution toward an even more efficient procedure.

Current Comment

FRACTIONATION OF SERUM PROTEIN

The electrophoretic method of protein fractionation appears to have become the standard of comparison for the older methods based on precipitation with neutral salts.[1] Serum proteins are separated on the basis of their rate of movement in an electric field, into the principal fractions, albumin and alpha, beta and gamma globulin; the albumin is the fastest moving compound, the gamma globulin the slowest moving. The fractionation obtained by precipitation with salt appears to be sensitive to the exact salt concentration employed; by choice of appropriate concentrations the albumin is made to correspond approximately with the electrophoretically determined albumin, the pseudoglobulin to the alpha and beta globulin and the euglobulin to the gamma globulin.[1] Thus it appears that salt fractionation may be used to give a fair approximation of the values obtained with the technically difficult electrophoretic method. The quantitative interpretation of electrophoretic data in terms of plasma protein concentration is complicated by the interference of lipid which migrates with the protein. Furthermore, the results obtained under different experimental conditions are not identical, and protein fractions appear at times to be bound together so that clear separation is not possible. A new approach to electrophoretic analysis which may partially overcome these interfering influences consists in preliminary fractionation with alcohol.[2] By means of this technic it has been found that the alpha and beta globulin of the blood of the rat are increased after thermal injury, and it appears that this may be a general response to tissue injury. Continued study of the proteins of serum promises to give a more complete understanding of the physiologic role of the various fractions.

TUBERCULOSIS IN OLDER AGE GROUPS

The belief seems prevalent that tuberculosis is a disease of youth or of comparative youth and that persons over 50 are seldom infected. Osler, whose "Principles and Practice of Medicine" perhaps more than any other single book has influenced medical thought in recent decades, states that although one seventh of the human race dies of tuberculosis, "a large proportion of all individuals become infected before reaching adult life." In Christian's 1947 revision of Osler's book, the statement appears that "no age is exempt. The disease is met with in the suckling and in the octogenarian, but fatal tuberculosis . . . is more common between the eighteenth and thirty-fifth years." According to necropsy experience, notably that of Medlar [1] at Bellevue Hospital, pathologically significant tuberculosis in persons under 40 is recognized clinically in a high proportion of all cases, while in those over 50 considerable numbers of cases occur but are overlooked clinically. In other words, in many tuberculous patients over 50 insufficient precautions are taken to prevent the spread of tuberculosis by these innocent carriers of tubercle bacilli. Medlar suggests that a method of approach to a solution of this problem would be the making of chest roentgenograms of all patients over 50 admitted to hospitals, regardless of other conditions. He states that all patients in "whom shadows are thought to be tuberculous in nature should have careful study by serial roentgenograms and for the discharge of tubercle bacilli, regardless of the first impression as to the significance of such shadows."

ELECTROLYTE LOSS IN DEHYDRATION

Many pediatricians have been the first to call attention to important biochemical problems and to the most effective means of solving them. A notable example of the latter tendency is the success with which Darrow and his associates at Yale, and for a period in Texas, have approached the problem of biochemical change in dehydration. This problem arose from the appalling mortality associated with infant diarrhea. In his William Buchanan Lecture,[1] Darrow emphasizes dehydration as the chief clinical feature of infant diarrhea and goes on to show that the dehydration is accompanied with unsuspected electrolyte shifts. Particularly important is the discovery of the magnitude of the loss of potassium from the cells of the body. This loss results in a series of secondary physiologic disturbances which may result in severe complications or death. It is not enough merely to attempt to restore water in dehydration. Careful attention must be paid to the disturbance in electrolyte balance, and fluid must be administered in such a way as to restore the electrolyte balance along with the water balance. The imbalance of electrolytes may be a prime factor in food intolerance. Darrow recommends a solution composed of 4.4 Gm. of sodium bicarbonate per liter, 2.7 Gm. of potassium chloride per liter and 3 Gm. of sodium chloride per liter. This solution contains more bicarbonate than serum, but less sodium, and about the same amount of chloride. The potassium concentration, however, is almost ten times that found in serum. This solution may be administered by continuous intravenous drip diluted in the ratio of 1 part to 2 parts of 5 or 10 per cent dextrose. The injection rate in infants should be at the rate of about 80 to 100 cc. per kilogram during the first twenty-four hours. The mortality from infant diarrhea has been greatly reduced by this treatment. These observations suggest the importance of a study to determine whether or not similar shifts in potassium occur in cases of dehydration associated with surgery. Among other problems associated with dehydration and electrolyte disturbances there may be an effect on enzyme systems. As in other instances in medicine, this significant advance calls attention to the need for many more studies.

ORGANIZATION SECTION

Official Notes

EIGHTH ANNUAL CONGRESS ON INDUSTRIAL HEALTH

The Council on Industrial Health will hold its Eighth Annual Congress on Industrial Health in the Cleveland Auditorium, Cleveland, on January 5 and 6, 1948 These dates, immediately precede the Interim Session of the American Medical Association, which will be held in the Auditorium on January 7 and 8. General practitioners supply a large part of the medical services which workers receive through industry, and they are cordially invited to attend these industrial health sessions. The program of the Congress is being constructed with general practitioners in mind and will include discussions of first aid and emergency services in industry, physical examinations, administrative practices, applied physiology, aviation medicine, radiation medicine and practical expositions of occupational disease management, traumatic surgery and rehabilitation. Since full use of medical services in industry depends on support from management and the worker, the essential relationships will be discussed. Industry needs medicine as a practical ally and to promote human relations. The Industrial Health Congresses are intended to further these objectives.

Washington Letter

(From a Special Correspondent)

Oct. 9, 1947.

Dr. Vannevar Bush to Coordinate All Military Research

President Truman has appointed Dr. Vannevar Bush chairman of the new Research and Development Board to take charge of all military research performed by the three service arms under the new unified defense command Dr. Bush was former chairman of the Wartime Office of Scientific Research and Development. He contributed to development of the atom bomb. John R. Steelman, assistant to the President, submitted the second in a series of five reports on "Science and Public Policy" to Mr. Truman as head of the President's Scientific Research Board. The report showed that the nation is spending $1,100,000,000 a year on science, including funds of the government, industry and educational institutions. It was estimated that more than $2,000,000,000 a year must be spent by 1957 if the United States is to keep abreast of scientific developments. The board stressed the need of military research during an "uneasy" world situation and mentioned that research of sixteen government agencies includes work of special interest to the members of the medical profession. The Naval Research Laboratory is working on separation of uranium isotopes. The U. S. National Museum is studying the effect of radioactivity on animal and plant life.

Taft Announces that GOP Will Seek Welfare Legislation Next Session

Senator Taft, Ohio Republican and contender for the GOP presidential nomination, told an Oregon audience on his current Western tour that a billion-dollar-a-year program of welfare legislation would have Republican party support and "would and should proceed" at the next session of Congress. He said that the program must be free of federal bureaucratic controls and must be administered at state and local levels on a basis of "federal assistance and not regulation." Senator Taft included in the field of necessary welfare legislation the review and supplementation of old age insurance; increased unemployment compensation under continued state control; more work relief limited to emergencies; a state-aid health plan to cost about $200,000,000 yearly, by which states could obtain free medical and hospital assistance for "those unable to pay for it"; encouragement of voluntary health funds; subsidized housing for those in the lowest income groups, confined to about 10 per cent of all new construction; federal aid to education so that at least a minimum education is provided for every child born in the United States.

Infantile Paralysis Sends Dr. Sabin to Germany to Study Polio Outbreak

Basil O'Connor, president of the National Foundation for Infantile Paralysis, announced that Dr. Albert B. Sabin, professor of research pediatrics, University of Cincinnati, had gone by air to Germany to investigate a severe outbreak of poliomyelitis. His purpose is to prevent spread of the crippling disease to the American occupation forces. Lieut. Gen. Lucius D. Clay, commander of the United States forces in Germany, had wired for services of an epidemiologist to advise on control methods.

Coming Medical Meetings

Conference of State Medical Society Secretaries and Editors, Chicago, A.M.A. Headquarters, Nov. 7-8. Dr. George F. Lull, 535 N. Dearborn St., Chicago 10, Secretary.

American Academy of Ophthalmology and Otolaryngology, Chicago, Palmer House, Oct. 12-17. Dr. W. L. Benedict, 102 Second Ave. S.W., Rochester, Minn., Secretary.

American Association of Railway Surgeons, Chicago, Nov. 23-25. Dr. Raymond B. Kepner, 547 West Jackson Boulevard, Chicago 6, Secretary.

American Clinical and Climatological Association, Colorado Springs, Oct. 13-15. Dr. James Bordley III, Johns Hopkins Hospital, Baltimore 5, Secretary.

American Otorhinologic Society for the Advancement of Plastic and Reconstructive Surgery, New York, Nov. 13. Dr. Norman N. Smith, 291 Whitney Ave., New Haven 11, Conn., Secretary.

American Society for the Study of Arteriosclerosis, Chicago, Hotel Knickerbocker, Nov. 2-3. Dr. O. J. Pollak, Wilmington General Hospital, Wilmington 14, Delaware, Secretary.

American Society of Anesthesiologists, New York, Hotel New Yorker, Dec. 4-5. Dr. Curtiss B. Hickcox, 745 Fifth Ave., Room 1503, New York 22, Secretary.

American Society of Clinical Pathologists, Chicago, Drake Hotel, Oct. 28-30. Dr. A. S. Giordano, 531 N. Main St., South Bend, Ind., Secretary.

American Society of Tropical Medicine, Atlanta, Ga., Dec. 2-4. Dr. Norman H. Topping, National Institute of Health, Bethesda 14, Md., Secretary.

Association of American Medical Colleges, Sun Valley, Idaho, Oct. 27-29. Dr. Fred C. Zapffe, 5 S. Wabash Ave., Chicago, Secretary.

Association of Military Surgeons of the United States, Boston, Nov. 13-15. Col. James M. Phalen, Army Medical Museum, Washington 25, D. C., Secretary.

Central Neuropsychiatric Association, Galveston, Texas, Oct. 17-18. Dr. William C. Menninger, 3617 W. Sixth Ave., Topeka, Kans., Secretary.

Delaware, Medical Society of, Wilmington, Oct. 13-15. Dr. John F. Hynes, Memorial Hospital, Wilmington, Secretary.

Indiana State Medical Association, French Lick, Oct. 28-30. Mr. Ray E. Smith, 23 E. Ohio St., Indianapolis 4, Executive Secretary.

Inter-State Postgraduate Medical Association of North America, St. Louis, Public Auditorium, Oct. 14-17. Dr. Tom B. Throckmorton, 406 Sixth Ave., Des Moines, Iowa, Secretary.

New England Postgraduate Assembly, Boston, Copley-Plaza Hotel, Oct. 29-31. Dr. Leroy E. Parkins, 8 Fenway, Boston 15, Chairman.

New York State Association of Public Health Laboratories, Albany, Nov. 7. Miss M. B. Kirkbride, New Scotland Ave., Albany 1, Secretary.

Oklahoma City Clinical Society, Oklahoma City, Biltmore Hotel, Oct. 27-30. Dr. Elmer R. Musick, 512 Medical Arts Bldg., Oklahoma City, Director of Clinics.

Omaha Mid-West Clinical Society, Omaha, Oct. 27-31. Dr. John M. Thomas, 1031 Medical Arts Bldg., Omaha 2, Secretary and Director of Clinics.

Post Graduate Medical Assembly of South Texas, Houston, Texas, Coliseum, Dec. 1-3. Dr. E. Trowbridge Wolf, 229 Medical Arts Bldg., Houston, Texas, Secretary.

Radiological Society of North America, Boston, Nov. 30-Dec. 5. Dr. Donald S. Childs, 607 Medical Arts Bldg., Syracuse 2, N. Y., Secretary.

Seaboard Medical Association of Virginia and North Carolina, Virginia Beach, Va., Dec. 2-5. Dr. Clarence Porter Jones, 3117 West Ave., Newport News, Va., Secretary.

Southern Medical Association, Baltimore, Nov. 24-27, Mr. C. P. Loranz, Empire Bldg., Birmingham 3, Ala., Secretary.

Southern Psychiatric Association, Birmingham, Ala., Oct. 13-14. Dr. Newdigate M. Owensby, 384 Peachtree St. N.E., Atlanta, Ga., Secretary.

Southwestern Medical Association, Phoenix, Ariz., Hotel Westward Ho, Nov. 6-8. Dr. Louis W. Breck, 116 Mills St., El Paso, Texas, Secretary.

Virginia, Medical Society of, Roanoke, Oct. 13-15. Miss Agnes V. Edwards, 1200 E. Clay St., Richmond 19, Secretary.

Western Surgical Association, Colorado Springs, Broadmoor Hotel, Dec. 4-6. Dr. Warren H. Cole, 1853 West Polk St., Chicago 12, Secretary.

GOVERNMENT SERVICES

VETERANS ADMINISTRATION

ESTABLISH SECTION OF RADIOISOTOPES

The chief medical director of the Veterans Administration and those of his staff responsible for the activities of the Research and Education Service desire to bring to the veterans, in the fullest measure and at the earliest time possible, the benefits of an "atomic era" in medicine. To provide direction for such an activity within hospitals of the Veterans Administration, the chief medical director has established a section on radioisotopes within the Research and Education Service of the central office. To implement this program, the chief of the radioisotope section will assume responsibility for overall coordination and supervision, and a Central Advisory Committee on Radioisotopes will make recommendations as to general policy and establish specific safety measures to be observed.

At six hospitals of the Veterans Administration radioisotopes will be employed during the current fiscal year in accordance with the recommendations of the Central Advisory Committee on Radioisotopes. These hospitals are uniquely situated with respect to university groups participating in the medical activities of the Veterans Administration, and representatives of these institutions are engaged in the use of radioisotopes within their university. It is possible, therefore, to have the program within the individual Veterans Administration hospital under the responsible direction of professional qualified personnel who in turn have associated with them a team of the various types of consultants required for such a program.

At each of the six hospitals the program will be under the general cognizance of a Committee on Radioisotopes which in turn will be a subcommittee of the Dean's Committee for that hospital. In this manner the relationship of the radioisotope program to the universities will be similar to that for medical care and for the educational program within the hospitals of the Veterans Administration.

The chief medical director desires that a sound radioisotope program be developed as quickly as good judgment and the availability of qualified personnel permit. To serve as chief, radioisotope section, in the central office Dr. George M. Lyon, Huntington, W. Va., has been appointed. To serve on the Central Advisory Committee on Radioisotopes the following have been appointed: Dr. Hugh J. Morgan, professor of medicine, Vanderbilt University School of Medicine, Nashville, Tenn.; Dr. Stafford L. Warren, professor of biophysics and dean, University of California Medical School, Los Angeles; Dr. Shields Warren, professor of pathology, Harvard Medical School, Boston; Dr. Hymer L. Friedell, professor of radiology, Western Reserve University School of Medicine, Cleveland, and Dr. Perrin H. Long, professor of preventive medicine, Johns Hopkins University School of Medicine, Baltimore. The hospitals of the Veterans Administration that will have active radioisotope programs during the current fiscal year are situated at Framingham, Mass.; Bronx, N. Y.; Cleveland; Chicago; Minneapolis, and Los Angeles.

TRAINING FOR HOSPITAL LIBRARIANS

A thirty day nationwide training program is being conducted by the Veterans Administration to acquaint its hospital librarians with the latest trends in medical library practices. The program will be under the supervision of Francis R. St. John, director of the Veterans Administration's library service, who said special training is necessary because of the acute shortage of medical record librarians. This phase of library work, he said, requires knowledge of medical literature as well as specialized technics in medical reference work, bibliography and research. With the ever increasing number of patients, the VA medical service requires medical libraries as a part of the facilities available to the medical staffs of its hospitals. To carry out the instruction of librarians, regional meetings were held in September in New York and will be held in October in St. Paul, Denver, St. Louis and Atlanta, Ga. These regional meetings will also serve to coordinate procedures in buying books, and in obtaining them faster and on a more economical basis.

SPECIAL PROGRAM OF AURAL REHABILITATION

The Veterans Administration has established a special program of medical rehabilitation to help overcome impairments in hearing suffered by about 30,000 veterans of World War II. The rehabilitation course includes a series of hearing and speech tests, the selection and fitting of a hearing aid if indicated, auditory training, instruction in lip reading and speech correction if necessary. Contracts have been made with some twenty-seven universities, clinics and institutions, and aural rehabilitation centers have been set up to give all or part of the complete rehabilitation course; in addition the complete course is also available at the Veterans Administration's New York regional office. If special surgery is required the operations will be performed at VA hospitals at Los Angeles and San Francisco and at the naval hospitals at Philadelphia and Bethesda, Md.

THE DOCTOR'S BILL

The following is an excerpt from an address by Dr. Paul R. Hawley, chief medical director of the Veterans Administration, given before the American War Dads at Fort Worth, Texas, September 29:

> Now, what is the doctor's bill that the government has to pay for the veteran? It varies a penny or two each month, but not more. In the month of June, which is the latest month for which I have complete figures, the total doctor cost—and this includes resident physicians, full time VA physicians, and all part time physicians and consultants, every doctor that has anything to do with our hospitals—the total doctor cost in our general medical and surgical hospitals, which are the most expensive to operate, was $1.47 per patient per day—exclusive of course of food and all other expenses. Think of this! This means that, if a veteran goes into one of our hospitals for appendicitis and is operated on and stays in the hospital for ten days, his bill for actual physicians' services, paid by the government, is only $14.70. Can you fathers and mothers buy even the cheapest medical service at such a ridiculous price? And, in most of our hospitals, even the millionaire cannot buy more and better doctors at any price, because this buys not only the surgeon that takes out the appendix but also the doctors who assist in the operation, the doctor who gives the anesthetic, the doctor who operates the laboratory which made the blood counts, the doctor who took the x-rays (if any were necessary) and the doctor who dressed the incision until it healed. I think you will agree that we are getting doctors' care at bargain prices.
>
> Our doctor cost, exclusive of other costs, is even less in our other two types of hospitals. In tuberculosis hospitals, it is 88 cents per patient per day; and in our mental hospitals it is the ridiculously low figure of 36 cents per patient per day. Can anyone want us to be more economical than that?
>
> But economy is only our secondary objective. Quality is our first objective, and will always be our first objective, so long as I have anything to do with this service. However, it so happens that the same factor which gives us quality in medical care also promotes economy in the cost of medical care. If we did not have residents in training in our hospitals, we would have to have almost the same number of full time VA staff physicians to replace them; and the salary paid a resident in training is not more than one-half that which we would have to pay for a full time VA physician to do exactly the same work. The reason for this is that a large part of the compensation of the resident is paid in terms of the training and experience he gets—and not in *money. Thus the resident profits, the* patient profits greatly and the government saves money. It is about the only business in the world where you get something for nothing.

HOSPITAL NEWS

The Veterans Administration has announced presidential approval of a 19.5 acre site for a five hundred bed hospital in Indianapolis adjacent to Indiana University.

LOUISIANA

Equine Encephalomyelitis.—The Associated Press reports that state and federal health authorities are working in southwest Louisiana in an effort to halt an epidemic of equine encephalomyelitis which has also spread to human beings with fatal results to two children. The disease is said to have killed 2,800 horses and mules in that section.

MARYLAND

Academy Meetings.—The Silver Spring Academy of Medicine, Silver Spring, has scheduled its meetings for the remainder of the year. They are to be held in the Montgomery County Building at 8:15 p.m.: On November 3 Dr. Emil Novak, professor of gynecology, Johns Hopkins University, Baltimore, will speak on "Indications, Limits and Hazards of Endocrine Therapy in Gynecology"; on December 1 Dr. Richard B. Cattell, Boston, will address the academy on "Pancreatic Surgery."

Baltimore Creates Department of Medical Care.—The city service commission of Baltimore in July created a new program designed to administer medical care to the public assistance clients of the city welfare department. The new medical care section will round out a statewide service that has already been in operation in the counties of Maryland under the state department of health. Heretofore the responsibilities of the Baltimore City Health Department have been exclusively in preventive medicine, excepting only curative medical services for persons with communicable diseases. Dr. Wendell R. Ames, commissioner of health, Cattaraugus County, Olean, N. Y., began duties as director of the new department early in September. After receiving his medical degree from Long Island College of Medicine, New York, he was a staff member of the New York State Department of Health for five years and was on the faculty of Albany Medical College, Albany, N. Y.

MINNESOTA

Personal.—Dr. Albert J. Chesley, St. Paul, secretary and cutive officer of the Minnesota State Board of Health since 1, was given an honorary life membership by the American ocial Hygiene Association recently. He has been a vice president and served as a member of the board of directors and of various special and standing committees.——Dr. Paul F. Dwan, Minneapolis, has been elected president of the Minnesota Heart Association.

Communities Honor Their Physicians.—Thief River Falls celebrated "Dr. Mellby Day" June 30 in recognition of Dr. Oscar F. Mellby's forty years of service to the community. President James L. Morrill of the University of Minnesota delivered the address. Dr. Mellby received his medical degree from the Minneapolis College of Physicians and Surgeons, and six years later began practice in Thief River Falls. He has been active in civic affairs and has served nine years on the Minnesota State Board of Health.——A homecoming celebration was held July 13 in honor of Dr. Mathias L. Ransom, Hancock, who has practiced in that city for forty-four years. Highlight of the celebration was a parade comprised entirely of persons whose birth Dr. Ransom attended.——Park Rapids and residents of surrounding communities celebrated "Dr. Higgs Day" July 27, the thirty-fifth anniversary of the arrival of Dr. Walter W. Higgs in Park Rapids as a practicing physician. At a program in a school park tribute was paid to Dr. Higgs by the principal speaker, Dr. Charles H. Pierce of Wadena.

NEBRASKA

Personal.—Dr. Albert S. Black Jr., formerly of the Mayo Clinic, Rochester, Minn., was recently appointed an assistant in plastic surgery at Creighton University School of Medicine, Omaha. Dr. Black is a graduate of Rush Medical College, Chicago, 1940.

Dr. Eggers Appointed to State Health Department.—Dr. Harold E. Eggers, Omaha, has been named director of the cancer control division of the state health department. In cooperation with the Nebraska State Medical Association and the American Cancer Society, the division expects to establish a central cancer registry in the state. There are 1,700 deaths from cancer in Nebraska each year, according to the state health director, and it is believed that early diagnosis and treatment will reduce this number. Dr. Eggers, a graduate of Rush Medical College, Chicago, 1909, recently retired from the University of Nebraska College of Medicine, where he had been a professor of pathology and bacteriology since 1916.

Clinical Society Assembly.—The Omaha Mid-West Clinical Society will hold its *fifteenth annual assembly* at the Hotel Paxton, Omaha, October 27-31. Out of state speakers include:

Dr. William F. Rienhoff Jr., Baltimore, Diagnosis and Surgical Treatment of Carcinoma of the Lung.
Dr. Nelson W. Barker, Rochester, Minn., Anticoagulant Therapy.
Dr. Theodore E. Sanders, St. Louis, Management of Some of the Common External Ocular Diseases.
Dr. Charles A. Weymuller, New York, Indications for Urologic Survey in Pediatrics.
Dr. Franklin G. Ebaugh, Denver, The Despecialization of Psychiatry.
Dr. William T. Green, Boston, Orthopedic Problems of Infancy and Childhood.
Dr. F. Bayard Carter, Durham, S. C., Origin and Management of Postpartum Hemorrhage.
Dr. Roy B. Henline, New York, Red Blood Cells in the Urine.
Dr. Warren B. Cole, Chicago, Tumors of the Pancreas and Pancreatitis.
Dr. Paul R. Cannon, Chicago, Nutritional Advances in Medicine and Surgery.
Dr. Walter L. Palmer, Chicago, Treatment of Intractable Peptic Ulcer.
Dr. Edward L. Bortz, Philadelphia, President of the American Medical Association, Statesmanship in Medicine.
Dr. John M. Adams, Minneapolis, Erythroblastosis Fetalis.

Included in the program are a series of local symposiums on convulsive disorders, immunization, low back pain, new therapeutic agents, obstetric problems and thyroid disease.

NEW JERSEY

Clinical Conference.—The *fifth clinical conference* of the Medical Society of New Jersey, under the auspices of the Passiac County Medical Society, will be held October 29, with morning sessions at St. Mary's and Passaic General hospitals in Passaic, Valley View Sanatorium, Nathan and Miriam Barnert Memorial Hospital, St. Joseph's and Paterson General hospitals in Paterson. The afternoon sessions will be held at the Alexander Hamilton Hotel, Paterson. Subjects under discussion will be: "Treatment and Prevention of Thrombophlebitis and Phlebothrombosis," "Rh Factor in Clinical Application," "Present Day Concept of Treatment of Syphilis," "The Clinical Aspects of Hepatitis," "Management of Arteriosclerotic Heart Disease" and recent advances in sulfonamide treatment, penicillin, streptomycin, cancer research and surgery of the gastrointestinal tract. At the evening session Dr. George Baehr, president of the New York Academy of Medicine, New York, will deliver the Elias J. Marsh oration on "The Continuing Education of Physicians; A Forecast of Imminent Changes."

NEW YORK

Graduate Lectures at Geneva.—The Medical Society of the State of New York and the New York State Department of Health have arranged two lectures for the Geneva Academy of Medicine at the Seneca Hotel at 8:30 p.m. On October 16 Dr. Earle B. Mahoney, Rochester, will speak on "Treatment of Burns." On December 18 Dr. William J. Orr, professor of pediatrics, University of Buffalo School of Medicine, will address the academy on "Modern Methods in Prevention and Treatment of Infectious Diseases."

State Loans X-Ray Equipment to Hospitals.—The New York State Department of Health has begun a new phase of its program in tuberculosis case finding by promoting routine chest roentgen examinations of patients admitted to hospitals, through the loan of complete x-ray equipment for making small films. Because of the limited number of state-owned x-ray units, only hospitals having 7,000 or more admissions a year can be accommodated. As more units become available the program will be extended to smaller hospitals. The objective is to make a roentgen examination of each patient 15 years of age and over who is admitted to a general hospital. To stimulate participation and help defray the cost, hospitals utilizing loaned equipment will be paid 50 cents for each report of an examination submitted. Any hospital desiring to use its own equipment will be reimbursed on the same basis if it conforms to the department's tuberculosis program. Interpretation of films is the responsibility of the hospital.

New York City

Study of Cancer in Fish.—The New York Aquarium will expand its study of cancer in fish under a $4,595 grant from the National Cancer Institute. The aquarium has been studying cancer through its cross breeding of fish for the last ten years.

Harvey Lecture.—Abraham White, Ph.D., associate professor of physiological chemistry, Yale University School of Medicine, New Haven, Conn., will deliver the first Harvey Lecture of the current series at the New York Academy of Medicine, October 23, on "Influence of Endocrine Secretions on the Structure and Function of Lymphoid Tissue."

Child Health and Welfare Committee.—At the organization meeting of the Child Health and Welfare Committee, County of Kings, July 22, it was decided to institute a study on the effect of illness of the mother during pregnancy on the new born, particularly the role which contagious diseases play in the causation of congenital anomalies. The department of health has offered its facilities. The plan is to appoint representatives of the committee in each hospital to investigate all cases of congenital anomalies. Dr. Henry Rascoff served as chairman.

Hospitals Aid Crippled Children.—Voluntary hospitals in New York City are providing more and more facilities for the correction of congenital crippling conditions in children, according to the United Hospital Fund The fund strongly urges parents to become acquainted with the facilities provided by its eighty-nine member institutions. These hospitals provide nearly six million days of bed care for more than one-half the total hospital patients in New York City, and their clinics provided more than three million visits to New Yorkers last year, the fund reports. Medical care and hospital services established by the United Hospital Fund's member voluntary hospitals are available to all who need them, regardless of race, creed or ability to pay.

Six Lectures on Psychiatry.—A series of six lectures on modern psychiatry will be given in the Town Hall Auditorium beginning October 20 at 5:30 p m and on the five succeeding Mondays. The series, under the auspices of the Town Hall short course division, will open with Dr. Carl A. L. Binger of Cornell University Medical College, speaking on "What Is Mental Health?" He will be followed by Dr. Edward A. Strecker of the University of Pennsylvania School of Medicine, Philadelphia, "The Psychiatric Implications of Immaturity"; Dr. Franz G. Alexander, Chicago Institute of Psychoanalysis, "What Is a Neurosis?"; Dr. Roy R. Grinker of Michael Reese Hospital, Chicago, "The Psychology of Middle-Aging"; Dr. Thomas A. C. Rennie, Cornell University Medical College, "What Is Psychotherapy?," and Dr. Frank Fremont-Smith, of the Josiah Macy Jr. Foundation, "Mental Health and World Citizenship."

Society for Speech and Voice Therapy.—The first meeting of the New York Society for Speech and Voice Therapy was held at the Academy of Medicine, October 8. Organized to promulgate the most modern knowledge and to stimulate further studies concerning speech and voice disorders, causes and treatment, the society will sponsor monthly lectures on subjects of scientific and practical interest. General membership is open to persons who are interested in the practice, study or teaching of speech and voice therapy and who, in addition, have any of the following qualifications: (1) a degree from any recognized college or university in speech or an allied subject; (2) a degree in medicine from a recognized institution, or (3) a position teaching or pursuing the clinical studies of speech and/or voice defects in a recognized institution. Applications may be addressed to Dr. Deso A. Weiss, 10 West Sixty-Fifth Street, New York 28.

New City Regulations Regarding Barbiturates.—Beginning November 1, to protect the public, prescribing and dispensing barbiturates in New York City will be governed by the following requirements of the Sanitary Code: 1. Barbiturates may not be dispensed except on written prescription; 2. Prescriptions for barbiturates may not be refilled unless there is specified on the prescription the number of times they may be refilled and the minimum interval that may elapse between refillings. 3. Under no circumstances may a prescription for barbiturates be refilled later than three months after the date of issuance. 4. Barbiturates may not be dispensed on a telephone order. 5. A copy of a barbiturate prescription cannot be filled; only an original is acceptable. 6. Barbiturates, including manufacturers' samples dispensed directly to a patient by a physician, must be given in a container on which the following information appears: (*a*) doctor's name and address; (*b*) patient's name and address; (*c*) directions for use, and (*d*) date of dispensing. 7. Prescriptions written for compounds containing barbiturates are exempt from the provisions of the new law if the compound contains, in addition to a barbiturate, such quantity of another drug or drugs as to make the action of the compound not primarily hypnotic or somnifacient and provided no such compound contains more than ¼ grain (15 mg.) of a barbiturate in each dose. Preparations used as sprays, gargles or for external application are also exempt if they contain, in addition to the barbiturate, ingredients which make the preparation unfit for internal use. The growing problem of the abuse of barbiturates has made the new regulations necessary. Seventy-seven accidental deaths in the city due to these drugs occurred in 1946 compared with 11 deaths in 1930. In addition the number of persons who have committed suicide by means of barbiturates has increased.

NORTH CAROLINA

Symposium on Diseases of Gastrointestinal Tract.—Duke University School of Medicine and Duke Hospital, Durham, will present the tenth annual medical symposium October 17-18 in Page Auditorium on the West Campus. Physician speakers on the program are:

Frank C. Mann, Rochester, Minn., Physiologic Factors in Relationship to Peptic Ulceration.
Walter L. Palmer, Chicago, Medical Management of Peptic Ulcer.
Leon J. Saul, Philadelphia, Psychosomatic Aspects of Peptic Ulcer.
Owen H. Wangensteen, Minneapolis, Studies in the Etiology and Surgical Management of Ulcer.
J. Arnold Bargen, Rochester, Minn., Differentiation of Various Forms of Ulcerative Colitis and Their Medical Management.
Henry W. Cave, New York, Surgical Treatment of Ulcerative Colitis.
Richard Schatzki, Cambridge, Mass., Roentgenologic Considerations in the Differentiation of Various Benign and Malignant Lesions of the Gastrointestinal Tract.
Stewart G. Wolf, New York, The Functions of the Stomach as Observed in Fistulous Human Subjects, with Special Reference to the Action of Drugs and the Effects of Vagotomy.
Richard H. Sweet, Boston, Treatment of Carcinoma and Inflammatory Stricture of the Esophagus by Resection and Primary Anastomosis.
Mandred W. Comfort, Rochester, Minn., Syndrome of Progressive Destruction of the Pancreas: Its Diagnosis and Treatment.
Robert Elman, St. Louis, Medical and Surgical Aspects of Inflammation of the Pancreas.
Alexander Brunschwig, New York, The Surgery of Pancreatic Tumors.

OHIO

Personal. — *Dr. Ralph B. Taylor, Columbus,* has been appointed a member of the Ohio State Medical Board for a period of seven years.——Dr. Hans G. Schlumberger has been appointed to the staff of the department of pathology, Western Reserve Medical School, Cleveland. Dr. Schlumberger graduated at the University of Pennsylvania School of Medicine, Philadelphia, in 1937 and taught there from 1939 to 1942.——Dr. Walter M. Simpson, Dayton, resigned as director of medical research for the Charles F. Kettering Foundation in Miami Valley Hospital, effective August 15. Dr. Simpson has been associated with the Kettering Foundation since 1927.

Open Cancer Clinic in Mansfield.—A cancer diagnostic clinic sponsored jointly by the Richland County Medical Society, the American Cancer Society and the Mansfield City-County Department of Health was opened September 9 in Mansfield. A grant in aid of approximately $12,000 has been recommended by the state health department to supplement local funds. The clinic is operated by the Cancer Committee of the medical society, headed by Dr. Henry T. Stiles, chairman. Dr. Willis E. Wygant is clinic director. The nursing services and public health aspects of the project are under Dr. Fred O. Tonney, city-county health officer. A panel of eighteen physicians has been selected for clinic duty.

PENNSYLVANIA

Society News.—At the annual dinner meeting of the Pennsylvania Psychiatric Society in Pittsburgh, September 18, Dr. Nolan D. C. Lewis, director of the New York State Psychiatric Institute, New York, spoke on "Social Aims and Organization of a Psychiatric Research and Teaching Center." Dr. LeRoy M. A. Maeder, Philadelphia, became president; Dr. Thomas A. Rutherford, Waymart, president-elect, and Dr. Philip Q. Roche, Philadelphia, secretary-treasurer.

Aid for Persons with Arrested Cancer.—The Pennsylvania Bureau of Rehabilitation in cooperation with the Pennsylvania division of the American Cancer Society has established a policy whereby persons with arrested cancer may apply for its services. Clients are eligible, with the exception of four year college training programs, if two qualified medical consultants decide that the disease is presumably arrested or eradicated and is an employment handicap. The program for persons requesting college education will be delayed for about three years from the date of original diagnosis and instituted only after the case has been reviewed again by two qualified consultants who are of the opinion that the disease is presumably arrested or eradicated and that an employment handicap exists.

Philadelphia

Schireson's License Revoked.—The State Board of Medical Education and Licensure on August 29 revoked the license of Dr. Henry J. Schireson to practice medicine in Pennsylvania on grounds that he had obtained his license June 29, 1910, by fraud. The case has been before the board, the Dauphin county court and the state supreme court for over three years (The Journal, Nov. 20, 1943, p. 790).

Assistant Director for Phipps Institute.—Dr. Russell E. Teague, surgeon reserve, U. S. Public Health Service, recently assigned to the Henry Phipps Institute at the University of Pennsylvania, Philadelphia, by the tuberculosis control division of the Public Health Service, has been appointed assistant director of the institute and assistant professor of public health in the university. Dr. Teague will divide his time between his new duties at the institute and his continuing responsibilities as consultant on tuberculosis for the New England States, New York, New Jersey, Delaware and Pennsylvania. He is a graduate of the University of Louisville School of Medicine, Louisville, 1929.

TEXAS

Equine Encephalitis.—An outbreak of eastern equine encephalitis among horses on Galveston Island has been investigated by Morris Pollard, director, Virus Laboratory, University of Texas Medical Branch, Galveston. Dr. Pollard identified the character of the epidemic in eastern Texas before it struck the lower Gulf Coast. The possibility of transmission to man is being carefully watched.

Houston Pediatrics Conference.—A pediatrics conference is scheduled to be held in Houston, October 13-18, under the sponsorship of Baylor University College of Medicine, Houston, University of Texas Child Health Program, Houston Guidance Center, the State Board of Health and the Texas Pediatric Society. Enrolment of pediatricians attending the conference at the expense of the state health department is limited to eighty, but others may attend on payment of a small tuition fee. The guest speakers are: Drs. Paul L. Boisvert, Yale University; Jules V. Coleman, University of Colorado School of Medicine, Denver; Harold W. Dargeon, Columbia University College of Physicians and Surgeons, New York; Milton E. Kirkpatrick, Tulane University of Louisiana School of Medicine, New Orleans; Robert A. Lyon, University of Cincinnati College of Medicine; Russell J. Blattner, Baylor University College of Medicine, Houston; J. Warner Duckett, Southwestern University Medical College, Dallas; Arild E. Hansen, University of Texas Medical Branch, Galveston; and Sumpter S. Arnim and Russell K. Smith, University of Texas School of Dentistry, Galveston; Paul C. Bucy and Douglas N Buchanan, University of Chicago, the School of Medicine, and Julian D. oyd, State University of Iowa College of Medicine, Iowa City.

WEST VIRGINIA

Society News.—At a meeting of the board of directors of the West Virginia Tuberculosis and Health Association in Charleston, September 18, Dr. William P. Bittinger, Summerlee, was reelected president; Dr. William L. Cooke, Charleston, vice president; Dr. James L. Patterson, Logan, secretary, and Robert C. Hawkins, Charleston, treasurer.

Urologists Form State Society.—At a meeting of urologists in Huntington, September 11, the West Virginia Urological Association was organized with the following officers: Dr. Richard D. Gill, Wheeling, president; Dr. Grattan G. Irwin, Charleston, vice president, and Dr. Charles A. Hoffman, Huntington, secretary-treasurer. The new association will seek formal affiliation with the West Virginia State Medical Association.

First City-County Health Merger.—The Kanawha-Charleston Health Department is the first health unit to be effected under the provisions of a bill passed by the legislature in 1947, which authorizes the consolidation of city and county health units. Dr. Leon A. Dickerson of Madison has accepted appointment as director of the new department for a term of four years beginning October 1. Dr. Dickerson, former county health officer for Boone County, is a graduate of the Medical College of Virginia, Richmond, 1935. He has also been county health officer for Lafayette County and venereal control health officer for the state department of health.

Expand Chest Diagnostic Facilities.—The present chest diagnostic facilities in the state will be expanded in a program sponsored by the state health department and the West Virginia Tuberculosis and Health Association, for which $10,000 was appropriated by the legislature. Diagnostic clinics served by clinicians are already in operation in Boone, Fayette, Logan, Marion, Marshall, Monongalia, Ohio and Harrison counties. Three counties, Kanawha, Hancock and Raleigh, have monthly x-ray clinics but do not have the services of a clinician. In Lewis, Wood, McDowell, Mingo, Mercer, Greenbrier and Berkeley counties organized groups are undertaking to establish regular monthly clinics with all facilities. Service in the other thirty-seven counties will be provided by a traveling unit staffed with a tuberculosis specialist. X-ray service will also be available as part of the state-sponsored program.

WISCONSIN

Dr. Ask-Upmark to Lecture at Madison.—Dr. Erik Ask-Upmark, professor of general medicine and neurology, the University of Upsala, Sweden, will speak at a meeting of the University of Wisconsin Medical Society, Madison, at 8 p. m. October 15 on "The Spleen and Some of Its Disorders." The meeting will be open to the public. Dr. Ask-Upmark was a fellow associated with the Rockefeller Foundation in 1932-1933, and he studied in Boston in the clinics of Harvey Cushing and Stanley Cobb. His appearance in this country is a result of the presentation of a series of lectures at the University of California Medical School, Berkeley-San Francisco, and his attendance at the recent Cancer Congress in St. Louis.

GENERAL

Brochure on Equipment for Cerebral Palsy Cases.—Zeta Tau Alpha, national women's sorority, will cooperate with the National Association for Crippled Children and Adults, cerebral palsy division, in publishing an equipment brochure for which funds have been appropriated. The guide will describe the therapeutic equipment needed and used in cerebral palsy cases and will include information about its construction and where it may be obtained. The sorority's one hundred and thirty-five alumnae groups will cooperate.

Dr. Connor Appointed Medical Director.—Dr. Charles A. R. Connor, New York, has been appointed medical director of the American Heart Association, succeeding Dr. David D. Rutstein, New York, who resigned to become professor of preventive medicine, Harvard Medical School, Boston. Dr. Connor graduated in 1931 from New York University College of Medicine, where since 1935 he has been an instructor in medicine. He was named associate physician in cardiovascular disease and assistant chief of the cardiovascular clinic, Lenox Hill Hospital, in 1946. He served in the U. S. Army as flight surgeon and consulting cardiologist in the recent war.

Dr. Kendall Emerson Given Trudeau Medal.—Dr. Kendall Emerson, New York, managing director of the National Tuberculosis Association since 1928, has been awarded the 1947 Trudeau medal for meritorious service in the campaign against tuberculosis in this country and abroad. The medal was presented at the annual meeting of the National Tuberculosis Association in San Francisco, June 17. Dr. Emerson is a graduate of Harvard Medical School, Boston, 1901. He served as executive secretary of the American Public Health Association from 1931 to 1935, is a consultant to the U. S. Public Health Service, councilor, Medical Council of the Veterans Administration, member of the executive committee of the International Union Against Tuberculosis and was a member of the U. S. Commission to the Pan American Sanitary Union meeting in Buenos Aires in 1934.

Meeting of National Society of Crippled Children and Adults.—The annual convention of the National Society of Crippled Children and Adults, Inc., will be held at the La Salle Hotel, Chicago, November 2-5, under the presidency of Col. Elbridge W. Palmer, Kingsport, Tenn. Physicians speaking on the program built around the theme, "The Handicapped—A Great National Resource," include:

Henry G. Poncher, Chicago, The Convalescent Child and His Needs.
Howard A. Rusk, New York, The Forgotten Casualty.
George G. Deaver, New York, Physical Demands of Daily Life.
Raymond T. Carhart, Ph.D., Chicago, Communication, Our Highway to Living.
Arnold L. Gesell, New Haven, Conn., Growth and Development of the Cerebral Palsied Child.

Physician members of the panel, "Needs for Rehabilitation Services," are Dr. Carl M. Peterson, secretary, Council of Industrial Health, American Medical Association, Chicago, chairman, and Dr. Harold A. Vonachen, Peoria, Ill.

International Meeting on Venereal Diseases.—The first postwar general assembly of the International Union Against the Venereal Diseases will be held at the Institut Fournier, 25 Boulevard St. Jacques, Paris, October 20-25, under the presidency of Dr. William F. Snow, New York. The United States delegation will include Dr. James A. Doull, Washington, D. C., the U. S. Public Health Service, chief of International Health Relations; Dr. John R. Heller Jr., chief, U. S. Public Health Service venereal diseases division, Bethesda, Md., and Miss Jean B. Pinney, director of the union's regional office for the Americas. International organizations with which especial cooperation is maintained aside from the World Health Organization are UNESCO's section on Natural Science, the International Labor Organization, International Council on Women, International Alliance of Women and the League of Red Cross Societies. It is expected that these agencies will be represented at the assembly, as well as many of the sixty-four national member agencies located in forty-five countries.

Prevalence of Poliomyelitis.—Reports of cases of poliomyelitis for the periods indicated have been received from the division of public health methods, U. S. Public Health Service.

Meeting of Association of American Medical Colleges.—The fifty-eighth annual meeting of the Association of American Medical Colleges will be held at Sun Valley, Idaho, October 27-29, under the presidency of Dr. William S. McEllroy, Pittsburgh. Arrangements have been made with the Union Pacific Railroad for special cars to leave Chicago for Sun Valley October 24 at 2 p.m., and a special train will leave Sun Valley October 29 at 8:30 p.m., to arrive in Chicago October 30 at 2:30 p.m. The program for the opening day follows:

Dr. Donald B. Tresidder, president, Stanford University, Stanford University-San Francisco, Aims and Objectives of Medical Education.
Dr. Alan M. Chesney, dean, Johns Hopkins University School of Medicine, Baltimore, Some Impacts of the Specialty Board Movement on Medical Education.
Dr. Byrl R. Kirklin, Rochester, Minn., Advisory Board for Medical Specialties, Basic Science Requirements for Specialty Certification.
Dr. Currier McEwen, dean, New York University College of Medicine, New York, Graduate and Postgraduate Training for Specialization.
Dr. Walter H. Moursund Jr., M. C., U. S. Army, A New Approach to Basic Science Instruction at the Postgraduate Level.
Dr. William S. McEllroy, dean, University of Pittsburgh School of Medicine, address of the president: The Association of American Medical Colleges.

TUESDAY

Dr. Thomas Parran, Surgeon General, U. S. Public Health Service, Washington, D. C., Shortage of Medical Personnel.
Francis J. Mullin, Ph.D., dean of students, University of Chicago Medical School, Selection of Medical Students.
H. Grant Taylor, assistant dean, Duke University School of Medicine, Durham, N. C., The Personal Interview of Applicants.
Dewey B. Stuit, Iowa City, director of study, Committee on Personnel Practices, The Discovery of Medical Talent.
Harold A. Shoemaker, assistant dean, University of Oklahoma School of Medicine, Oklahoma City, and John H. Rohrer, Relationship Between Success in the Study of Medicine and Certain Psychologic and Personal Data.

WEDNESDAY

Dr. Stuart W. Lippincott, University of Washington School of Medicine, Seattle, Teaching of Clinical Laboratory Methods.
Joseph H. Gast, Sc.D., Baylor University College of Medicine, Houston, Texas, Teaching of Medical Biochemistry.
Dr. Edgar J. Poth, University of Texas School of Medicine, Galveston, Texas, Correlation and Continuation in Medical Education.
Dr. Richard H. Young and George A. Pierson, Ed.D., University of Utah School of Medicine, Salt Lake City, The Professional Aptitude Test—1947: A Preliminary Evaluation.
Dr. Ernest W. Brown, Chicago. Committee on Scientific Development of the Council on Industrial Health, American Medical Association, The Place of Occupational Medicine in the Undergraduate Curriculum.

FOREIGN

Salvation Army Leprosariums in India.—The public relations department of the Salvation Army, 120 West Fourteenth Street, New York, announces that the Salvation Army has been working among leprous persons in India for the past seventeen years and has three leprosariums directed by Salvation Army medical personnel located at Bupatala in Madras province, Puthankruza in the state of Travancore and Karati in Cochin state. Nine hundred patients are being treated in the three hospitals. Major Hilda Plummer, who spent the last fourteen years in India organizing leprosariums, returned to the United States in March and has studied at the U. S. Marine Hospital for the treatment of leprosy at Carville, La. Major Plummer states that the new Indian provincial governments are turning to foreign medical and mission groups who have been doing medical work in India to help them establish adequate medical services for their people. The one condition they insist on is that every effort be made to instruct and train native Indians to take over the work. Besides operating leprosariums, the Salvation Army medical staffs in India maintain clinical service for persons in the early stages of leprosy and also treat patients in their homes. The Salvation Army hopes to extend its work with the leprous to other states and provinces. The greatest need at present is said to be for medical and mission personnel and specialized equipment. The Salvation Army medical work in India is financed largely through self denial weeks among its own members throughout the world, whereby each person foregoes some necessity and donates the money for this work.

Marriages

NORMAN FRANCIS WYATT, Petersburg, Va., to Miss Frances Jay Cushman of Westwood, Mass., in Dedham, Mass., September 6.

ROBERT SCHUESSLER GRAVES, Gadsden Ala., to Miss Faye Lucile Hunsucker of Charlotte, N. C., in Panama City, Fla., July 30.

HOLMES BUCK SPRINGS Jr., Myrtle Beach, S. C., to Miss Shirley Jean Wurst of Palmyra, N. J., at Dublin, Ga., August 29.

NESTOR WILLIAM WAWRO, Ansonia, Conn., to Miss Judith Aileen Winslow Stoughton of West Hartford August 23.

THOMAS BAYTON SUITER, Rocky Mount, N. C., to Miss Antoinette Culler Smith of Wellesley Hills, Mass., at Orangeburg, S. C., August 16.

FRANKLIN W. ROUSH, St. Petersburg, Fla., to Mrs. Julia M. Rhoads in Hillsboro, Texas, September 4.

EDWIN LEROY SCOTT, Augusta, Ga., to Miss Charlotte Marion Conaway in Columbia, S. C., September 15.

ELMER JACOBS HARRIS, Scottsboro, Ala., to Miss Ellen Virginia Moncrief of Prattville, recently.

EUGENE WESLEY GORDON, Oneonta, Ala., to Miss Lois Alene Savage of Montgomery, June 28.

WALTER A. MCLEOD, Jr., St. Petersburg, Fla., to Miss Ada B. Hurley of Detroit, recently.

JOHN E. DEES to Miss Elizabeth Osgood Gautier, both of Miami, Fla., June 21.

WILLIAM F. CONNELL to Miss Kathryn Rose Harrigan, both of Pittston, Pa., July 26.

Deaths

William Charles White, Washington, D. C.; born in Woodstock, Ontario, Canada, September 3, 1874; M.B., University of Toronto Faculty of Medicine, Toronto, Canada, 1898, and M.D., in 1901; did postgraduate work at universities in Leipzig and Heidelberg in Germany; professor of pathology at the Central College of Physicians and Surgeons, later known as the Indiana Medical College, School of Medicine of Purdue University, Indianapolis, from 1900 to 1905, when he became professor of neuro-anatomy and clinical psychiatry, Indiana University School of Medicine, Indianapolis, serving until 1907; associate professor of medicine at the University of Pittsburgh School of Medicine from 1908 to 1916; medical director of the Tuberculosis League Hospital of Pittsburgh and director of the R. B. Mellon Research Laboratory from 1907 to 1923, when he became a consultant to the U. S. Public Health Service; member of the Association of American Physicians, American Association for the Advancement of Science, American Clinical and Climatological Association, American Sanatorium Association, American Association of the History of Medicine, New York Academy of Medicine and others; honorary member of the Tuberculosis Society of Scotland; president of the National Tuberculosis Association from 1933 to 1936 and for many years chairman of the association's medical research committee; past president of the District of Columbia Tuberculosis Association; affiliated with the National Research Council in various capacities; during World War I director of the division for relief and prevention of tuberculosis of the American Red Cross in France and Italy; at one time chairman of consultants on hospitalization under the Secretary of the U. S. Treasury; in 1932 appointed a delegate and chairman of the conference of the International Union Against Tuberculosis in Amsterdam; received the Serbian Order of Saint Sava and the Commendatore of the Order of the Crown of Italy; in 1940 awarded the Trudeau Medal of the National Tuberculosis Association; chairman of the advisory committee to the health department of Washington; at the time of his death director of the District of Columbia Cancer Society, Washington Home for Foundlings and the Warwick Memorial Clinic; died in Westmoreland Hills, Md., August 10, aged 72, of heart disease.

Le Grand Guerry, Columbia, S. C.; born in Florence, Feb. 3, 1873; University of Georgia Medical Department, Augusta, 1896; honorary member and past president of the South Carolina Medical Association; member of the American Medical Association; member and formerly vice-president of the American Surgical Association; fellow of the American College of Surgeons; past president of the Southern Surgical Association, Columbia Medical Society and the Tri-State Medical Association; member of the founders' group of the American Board of Surgery; at one time on the faculty of his alma mater; received the degree of doctor of civil law from the University of the South, Sewanee, Tenn., in 1924, doctor of laws from University of South Carolina in 1928 and doctor of science from the University of Georgia in 1931; for many years surgeon at Columbia Hospital, where in 1947 a plaque was unveiled and a wing of the hospital named in his honor and where he died August 14, aged 74, of heart disease.

Edwin Baker Goodall, Boston; born in Jefferson, N. H., July 17, 1882; Maryland Medical College, Baltimore, 1905; University of Maryland School of Medicine, Baltimore, 1909; member of the American Medical Association, American Academy of Ophthalmology and Otolaryngology and the New England Ophthalmological Society; specialist certified by the American Board of Ophthalmology; served during World War I; instructor in ophthalmology at the Harvard Medical School; affiliated with the Massachusetts Eye and Ear Infirmary and Children's Hospital; consulting ophthalmologist to Cambridge (Mass.) Hospital; died August 6, aged 65.

Jay Frank Auner ⊕ Des Moines; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1897; specialist certified by the American Board of Dermatology and Syphilology; on the staffs of Iowa Lutheran Hospital and Iowa Methodist Hospital, where he died August 17, aged 74.

Fannie Elizabeth Barrett, Kalamazoo, Mich.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1899; for many years school medical inspector of Kalamazoo and on the staff of Kalamazoo State Hospital; affiliated with the Borgess and Bronson hospitals; died August 10, aged 77.

Orrin Curtis Blair ⊕ Lynn, Mass.; Harvard Medical School, Boston, 1903; fellow of the American College of Surgeons; on the staff of Lynn Hospital, where he died August 3, aged 67, of cerebral hemorrhage and diabetes mellitus.

Arpad Braun, Cleveland; Northwestern University Medical School, Chicago, 1925; member of the American Medical Association; died July 15, aged 51, of heart disease.

John Graham Brooks, New Rochelle, N. Y.; Fordham University School of Medicine, New York, 1921; affiliated with New Rochelle Hospital; died August 1, aged 50.

William Patrick Burns, Washington, D. C.; Chicago Medical School, 1915; died in Atlantic City, N. J., August 28, aged 54.

Haldor Carlsen, Chicago; Bennett Medical College, Chicago, 1913; member of the American Medical Association; on the staffs of the Edgewater, Swedish Covenant, Belmont and Norwegian American hospitals; died in Sparta, Wis., August 1, aged 62.

Albion C. Christian, Irvington, N. J.; Western Reserve University Medical Department, Cleveland, 1887; for many years member and at various times president of the board of education; served on the staff of Irvington General Hospital, where he died July 29, aged 81, of congestive heart disease and arteriosclerosis.

James Patrick Collins, Glendale, Calif.; Rush Medical College, Chicago, 1902; at one time a police surgeon in Chicago; died August 1, aged 69, of lobar pneumonia.

W. Pingree Curtis, Chicago; Dearborn Medical College, Chicago, 1905; member of the American Medical Association; affiliated with Woodlawn Hospital; died August 22, aged 67, of coronary thrombosis.

Walter Elmer D'Arcy, Trenton, N. J.; born in Trenton, N. J., 1886; Hahnemann Medical College and Hospital of Philadelphia, 1909; member of the American Medical Association; fellow of the American College of Surgeons; past president of the Mercer County Medical Society; president of the board of education; consulting surgeon, New Jersey State Village for Epileptics, Skillman; medical director and a member of the board of directors of McKinley Hospital, where he died July 23, aged 61, of acute lymphatic leukemia.

Anthony Foster De Graffenried, Bayside, N. Y.; University of Louisville (Ky.) Medical Department, 1911; for many years on the staff of Flushing (N. Y.) Hospital; died August 9, aged 62, of heart disease.

Charles Moore DeValin ⊕ Medical Director, Captain, U. S. Navy, retired, Philadelphia; Columbian University Medical Department, Washington, D. C., 1891; fellow of the American College of Surgeons; entered the U. S. Navy on Jan. 30, 1892; retired Aug. 1, 1933, on, or after, attaining statutory age; in 1924 a delegate from U. S. Navy to the American Medical Association; died at the Naval Hospital in Brooklyn June 8, aged 77, of arterial hypertension.

James Garfield Dwyer ⊕ New York; Queen's University Faculty of Medicine, Kingston, Ontario, Canada, 1905; specialist certified by the American Board of Otolaryngology; member of the American Academy of Ophthalmology and Otolaryngology and the American Otological Society; member and past president of the American Laryngological, Rhinological and Otological Society; affiliated with the Manhattan Eye, Ear and Throat Hospital; died in Kingston, Ontario, Canada, August 2, aged 65.

James Henry Ferguson, Clifton, Va.; Medical College of Virginia, Richmond, 1890; member of the American Medical Association; died August 1, aged 80, of arteriosclerosis and heart disease.

Irving H. Fowle, Milwaukee; Milwaukee Medical College, 1900; died August 1, aged 73.

Dugald Allan Galbraith, Lansing, Mich.; Detroit College of Medicine, 1905; member of the American Medical Association; affiliated with the Sparrow Hospital and St. Lawrence Hospital; died August 1, aged 72, of pulmonary edema.

John Conrad Giever, Spalding, Neb.; John A. Creighton Medical College, Omaha, 1920; member of the American Medical Association; served during World War I; for many years mayor of Spalding; city physician; died August 8, aged 54, of coronary occlusion.

Jacob Glauser, Philadelphia; Temple University School of Medicine, Philadelphia, 1928; also a graduate in pharmacy; served in the Atlantic and Pacific theaters during World War II; on the staffs of St. Mary's Hospital and St. Luke's and Children's Medical Center; died in the Jewish Hospital August 6, aged 49, of cerebral accident and ureterolithiasis.

Robert Hosea Good, Oak Park, Ill.; Rush Medical College, Chicago, 1902; member of the American Medical Association; past president of the Chicago Otolaryngological Society; served on the staffs of Garfield Park Hospital in Chicago and West

Suburban Hospital; died in Los Angeles August 28, aged 74, of gastric hemorrhage.

Louis Ammon Gould ⊕ Syracuse, N. Y.; Syracuse University College of Medicine, 1904; at one time on the faculty of his alma mater; served as school physician and for many years as physician for the city welfare department; formerly on the staffs of Syracuse University Hospital and Syracuse Free Dispensary; died August 1, aged 71, of coronary thrombosis.

Charles Herbert Johnson, Camden, N. J.; University of Maryland School of Medicine, Baltimore, 1909; died in Cooper Hospital July 12, aged 65, of injuries received in a fall.

Evelyn Ellen Annie Lowe, Brooklyn; Boston University School of Medicine, 1897; died August 2, aged 79.

Herbert Hall McAdams ⊕ Jonesboro, Ark.; University of Tennessee College of Medicine, Memphis, 1915; served as president of the school board; on the staff of St. Bernard's Hospital; died July 11, aged 63, of lymphatic leukemia.

Charles Milton McCoy, Lewistown, Pa.; Hahnemann Medical College and Hospital of Philadelphia, 1904; on the staff of Lewistown Hospital; died July 3, aged 73, of heart disease.

Robert Hugh McDonald ⊕ Cleveland; University of Toronto Faculty of Medicine, Toronto, Canada, 1922; diplomate of the National Board of Medical Examiners; fellow of the American College of Physicians; on the staff of the Cleveland Clinic; died July 20, aged 52.

James Gerard McGrath ⊕ Chicago; Loyola University School of Medicine, Chicago, 1921; on the staffs of Mercy and St. Anne's hospitals; died in the Mayo Clinic, Rochester, Minn., July 22, aged 52.

Ledge Wynn McNeill, Bartow, Fla.; University of West Tennessee College of Medicine and Surgery, Memphis, Tenn., 1912; died in the Morrell Memorial Hospital, Lakeland, July 16, aged 65, of coronary thrombosis.

Lawrence Theodore McNerthney ⊕ Tacoma, Wash.; Creighton University School of Medicine, Omaha, 1932; died in American Lake July 26, aged 40, of coronary thrombosis.

Frank Braun McNierney ⊕ Toledo, Ohio; University of Pennsylvania Department of Medicine, Philadelphia, 1908; formerly affiliated with the U. S. Public Health Service; medical examiner for the U. S. Marine Service; on the staff of St. Vincent's Hospital, where he died July 19, aged 63, of hypertension and cerebral thrombosis.

Thomas J. Mansfield, Muncie, Ind.; American Eclectic Medical College, Cincinnati, 1890; member of the American Medical Association; died July 22, aged 86, of carcinoma.

Harold Edward Marsh ⊕ Madison, Wis.; Tufts College Medical School, Boston, 1913; served in France during World War I; formerly affiliated with the Mayo Clinic in Rochester, Minn.; member of the staff of the Jackson Clinic; died July 12, aged 54, of lymphoblastoma.

Enoch Mather, Mount Clemens, Mich.; American Eclectic Medical College, Cincinnati, 1884; Medical University of Ohio, Cincinnati, 1886; National Medical College, Chicago, 1898; died July 7, aged 89, of arteriosclerosis.

William Ernest Merritt, Fancy Farm, Ky.; Marion-Sims-Beaumont Medical College, St. Louis, 1902; member of the American Medical Association; died July 4, aged 69, of carcinoma.

Albert W. Meyer, Bloomington, Ill.; Rush Medical College, Chicago, 1897; member of the American Medical Association; served as city physician and health officer; for many years on the U. S. Board of Pension Examiners; served as a member and president of the staff of St. Joseph's Hospital; died July 26, aged 77, of myocarditis.

Frederick Mason Miller, Binghamton, N. Y.; New York University Medical College, New York, 1896; fellow of the American College of Surgeons; member of the American Medical Association; on the staff and formerly member of the board of managers of Binghamton City Hospital; chief surgeon of the Erie Railroad; died July 9, aged 77, of coronary thrombosis.

John Welch Miller, Kansas City, Mo.; Kansas City Medical College, 1896; served on the staff of St. Margaret's Hospital in Kansas City, Kan.; died July 20, aged 91, of cardiovascular renal disease.

Harry Herbert Moore, Stafford Springs, Conn.; University of Vermont College of Medicine, Burlington, 1899; on the staff of Cyril and Julia C. Johnson Memorial Hospital; died in Hartford (Conn.) Hospital July 8, aged 78, of carcinoma of the prostate.

Joseph Hallock Moore ⊕ Huntington, W. Va.; State University of Iowa College of Medicine, Iowa City, 1929; diplomate of the National Board of Medical Examiners; specialist certified by the American Board of Otolaryngology; member of the American Academy of Ophthalmology and Otolaryngology; president of the West Virginia Academy of Otolaryngology; on the staffs of St. Mary's, Memorial and Veterans' hospitals; died suddenly, August 3, aged 45, of coronary occlusion.

Everett L. Morgan, Graham, Mo.; Central Medical College of St. Joseph, 1895; served during World War I; died in St. Francis Hospital, Maryville, July 12, aged 79, of uremia.

Edward Francis Murray, Burlington, Vt.; University of Vermont College of Medicine, Burlington, 1892; served during World War I; lieutenant colonel, medical reserve corps, U. S. Army, not on active duty; on the staff of Bishop DeGoesbriand Hospital; died July 20, aged 79, of arteriosclerotic heart disease.

Charles Patterson Nash, Alderson, W. Va.; College of Physicians and Surgeons, Baltimore, 1884; died July 12, aged 88.

Grant Vern Newcomer, Elwood, Ind.; Central College of Physicians and Surgeons, Indianapolis, 1891; served as city and county health officer; on the staff of Mercy Hospital, where he died July 9, aged 80, of cerebral hemorrhage.

Samuel Nicholas ⊕ *Philadelphia; University of the South* Medical Department, Sewanee, Tenn., 1904; also a pharmacist, affiliated with the Doctors' Hospital; died July 9, aged 67, of coronary occlusion.

Vernon Lee Norwood, Baltimore; University of Maryland School of Medicine, Baltimore, 1885; died July 13, aged 85, of cerebral arteriosclerosis and right hemiplegia.

George Edwin Obrist ⊕ Portsmouth, Ohio; University of Cincinnati College of Medicine, 1928; served as secretary treasurer of the Hempstead Academy of Medicine; shot and killed by an unknown assailant August 1, aged 45.

Lewellington D. Peck, Hastings, Minn.; Minneapolis College of Physicians and Surgeons, medical department of Hamline University, 1902; member of the American Medical Association; secretary and past president of the Dakota County Medical Society; served as mayor of Hastings, member of the school board and as an alderman; affiliated with St. Francis Hospital; died in St. Mary's Hospital, Rochester, Minn., July 4, aged 69, of cerebral thrombosis.

Alexander Monroe Peter, Whitesville, Mo.; Northwestern Medical College, St. Joseph, 1891; on the staff of Missouri Methodist Hospital in St. Joseph, where he died July 5, aged 77, of arteriosclerosis.

Edward John Phillips ⊕ Bradford, Pa.; University of Michigan Homeopathic Medical School, Ann Arbor, 1914; past president of the McKean County Medical Society; veteran of the Spanish-American War and World War I; physician for the public schools; served as a member of the Civil Service Board, on the defense board and examiner for the Selective Service Board; on the staff of the Bradford Hospital, where he died July 8, aged 72, of coronary occlusion.

Albert Winfrey Pigford ⊕ Tulsa, Okla.; Mississippi Medical College, Meridian, 1907; fellow of the American College of Surgeons; past president of the Tulsa County Medical Society; served during World War I; on the staff of the Claremore (Okla.) Indian Hospital; member of the consulting staff of St. John's Hospital; died July 26, aged 63, of carcinoma of the prostate.

Perry Charles Pluenneke, Overton, Texas; Southwestern University Medical College, Dallas, 1911; member of the American Medical Association; served during World War I; died in Dallas July 1, aged 59.

William Thomas Potter, Norfolk, Va.; Medical College of Virginia, Richmond, 1910; member of the American Medical Association; died in Norfolk General Hospital July 17, aged 59.

Allen Courtland Prichard, Hot Springs National Park, Ark.; Eclectic Medical College, Cincinnati, 1913; past president of the Arkansas Eclectic State Medical Board; died July 12, aged 64, of coronary occlusion.

Harry Philip Rank, Pine Grove, Pa.; Jefferson Medical College of Philadelphia, 1897; died July 26, aged 72, of coronary thrombosis.

Thomas W. Ranson, Cleveland; Cleveland University of Medicine and Surgery, 1894; died in Soldiers' and Sailors' Memorial Hospital in Penn Yan, N. Y., July 12, aged 77.

Frederick Cornwall Reed ⊕ Schenectady, N. Y.; Albany Medical College, 1902; past president of the Schenectady County Medical Society; served in various capacities on the staff of Ellis Hospital; died July 21, aged 72, of chronic endocarditis.

Walter Kellogg Reed ⊕ Boulder, Colo.; Northwestern University Medical School, Chicago, 1916; served during World War I; died in Alta Bates Hospital, Berkeley, Calif., July 11, aged 55, of cerebral hemorrhage.

William Carl Rentz, Miami, Fla.; Emory University School of Medicine, Atlanta, 1915; member of the American Medical Association; for many years affiliated with the Indian Service; associate attending physician at James M. Jackson Memorial Hospital; died July 8, aged 60, of cerebral hemorrhage.

Horace M. Robbins, Portland, Ore.; Tennessee Medical College, Knoxville, 1901; formerly a resident in Fossil, where he served as mayor, county health officer and coroner; served on the staff of the Dallas (Ore.) Hospital; died in the Hahnemann Hospital July 16, aged 80, of ulcer of the duodenum.

Joseph John Roberts ⊕ Baltimore; University of Maryland School of Medicine and College of Physicians and Surgeons, Baltimore, 1916; president of the Society of Anesthesiology in Baltimore; on the staffs of the Bon Secours Hospital, Maryland General Hospital and St. Joseph's Hospital, where he died July 16, aged 58, of coronary occlusion.

Ethel Blackwell Robinson, New York; Woman's Medical College of the New York Infirmary for Women and Children, New York, 1895; died in Huntington, L. I., July 31, aged 76, of carcinoma.

Joseph A. Robinson, Darlington, S. C.; Howard University College of Medicine, Washington, D. C., 1893; died July 2, aged 79, of carcinoma of the prostate.

Ursula Joan Roche, New York; New York University College of Medicine, 1936; member of the American Medical Association; specialist certified by the American Board of Internal Medicine; on the staffs of the Bellevue and Lenox Hill hospitals; drowned while swimming at Quogue, L. I., July 23, aged 35.

John Hubley Schall ⊕ Brooklyn; Hahnemann Medical College and Hospital of Philadelphia, 1893; an Affiliate Fellow of the American Medical Association; fellow of the American College of Surgeons; formerly on the staff of the Cumberland Street Hospital; for many years on the staff of the Prospect Heights Hospital, where he died July 10, aged 75.

Theodore W. Schmidt, Cincinnati; Medical College of hio, Cincinnati, 1889; for many years affiliated with St. Mary's ospital, where he died August 2, aged 82.

John Elmer Snodgrass, Fort Myers, Fla.; Hahnemann Medical College and Hospital of Philadelphia, 1902; died July 9, aged 69, of heart disease.

Mary Lydia Hastings Arnold Snow, New York; Cooper Medical College, San Francisco, 1897; died in the Memorial Hospital of Greene County, Catskill, July 11, aged 79, of cerebral hemorrhage and cerebral arteriosclerosis.

Isidore Steinman ⊕ New York; Columbia University College of Physicians and Surgeons, New York, 1918; died June 24, aged 60, of heart disease.

Samuel Joseph Veach, Atwood, Ill.; Barnes Medical College, St. Louis, 1907; member of the American Medical Association; died in Douglas County Jarman Hospital, Tuscola, July 3, aged 78, of nephritis.

Walter Eugene Vogt, Brooklyn; Cornell University Medical College, New York, 1903; member of the American Medical Association; attending gynecologist at Bushwick Hospital; died June 27, aged 66, of coronary thrombosis.

William Walter, Bethlehem, Pa.; Jefferson Medical College of Philadelphia, 1890; died July 19, aged 81, of cerebral hemorrhage.

Willibald John Wehle, West Bend, Wis.; Wisconsin College of Physicians and Surgeons, Milwaukee, 1897; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1898; member of the American Medical Association; died in St. Petersburg, Fla., June 9, aged 76, of arteriosclerosis and diabetes mellitus.

John Montgomery West ⊕ Allentown, Pa.; Johns Hopkins University School of Medicine, Baltimore, 1901; on the staff of Allentown Hospital, where he died July 7, aged 71, of carcinoma of the prostate.

Carl Westman ⊕ Chicago; Bennett Medical College, Chicago, 1898; an Affiliate Fellow of the American Medical Association; formerly on the faculty of the University of Illinois College of Medicine; at one time physician for the White Sox; formerly on the editorial board of the *Journal of Physical Therapy;* died July 2, aged 78, of cerebral hemorrhage and hypostatic pneumonia.

Edgar S. Whaley, Carlisle, Ark.; Memphis (Tenn.) Hospital Medical College, 1910; member of the American Medical Association; past president of the Lonoke County Medical Society; local surgeon for the Rock Island Railroad; died June 13, aged 64, of heart disease.

Myron Treadway Whipple, Chicago; Medical College of Ohio, Cincinnati, 1893; member of the American Medical Association; died June 26, aged 80, of chronic nephritis and uremia.

Roy Elson Wiant, Detroit; Jefferson Medical College of Philadelphia, 1913; member of the American Medical Association; died June 19, aged 60, of heart disease.

Mary Wickens ⊕ Richmond, Ind.; Indiana Medical College, School of Medicine of Purdue University, Indianapolis, 1906; specialist certified by the American Board of Psychiatry and Neurology, Inc.; for many years affiliated with the Richmond State Hospital, Easthaven; died in Reid Memorial Hospital July 2, aged 73.

Claude Warren Williams, Pawhuska, Okla.; University of Wooster Medical Department, Cleveland, 1898; also a graduate in pharmacy; served during World War I; formerly affiliated with the U. S. Public Health Service Reserve and the U. S. Veterans' Hospital in Atlanta; died August 3, aged 74.

Ralph Williams, Los Angeles; University of Southern California College of Medicine, Los Angeles, 1893; member of the American Urological Association; fellow of the American College of Surgeons; formerly on the faculty of his alma mater; died in the Hollywood Presbyterian Hospital, June 24, aged 75, of shock following an operation for cancer.

Alpheus Keller Wilson, Jacksonville, Fla.; Medical College of the State of South Carolina, Charleston, 1909; member of the American Medical Association; specialist certified by the American Board of Otolaryngology; member of the American Academy of Ophthalmology and Otolaryngology; fellow of the American College of Surgeons; an examiner for local selective service board during World War II; affiliated with Duval County and St. Luke's hospitals; died in a local hospital July 24, aged 67, of coronary thrombosis.

Jules Alexander Wimberly, Chicago; Baylor University College of Medicine, Dallas, Texas, 1924; member of the American Medical Association; fellow of the American College of Surgeons; served on the staff of St. Joseph's Hospital; died July 26, aged 51, of cerebral hemorrhage and hypertension.

Adolph Mitchell Wood ⊕ Shelbina, Mo.; Missouri Medical College, St. Louis, 1899; served during World War I; secretary of the Shelby County Medical Society; died in the Veterans' Hospital in St. Louis, July 11, aged 68, of heart disease.

Walter Allen Wood, Oberlin, Ohio; University of Pennsylvania Department of Medicine, Philadelphia, 1901; member of the Medical Society of the State of Pennsylvania and the American Medical Association; served in France during World War I; for many years medical referee for the New York Life Insurance Company; died in Allen Hospital June 23, aged 73.

Thomas Eddy Wyatt, Louisville, Ky.; University Medical College of Kansas City, Mo., 1900; served during the Spanish American War and World War I; contract surgeon for the U. S. Army; died July 21, aged 70, of coronary thrombosis.

Henry Amos Wyllys, Palatka, Fla.; Northwestern University Medical School, Chicago, 1900; served on the staffs of the Proctor and St. Francis hospitals in Peoria, Ill.; died July 17, aged 71 of cirrhosis of the liver.

Harris H. Zimmerman, Red Bluff, Calif.; Medical College of Indiana, Indianapolis, 1902; for many years served as health officer; died July 7, aged 75.

PUBLIC HEALTH SERVICE

Pasquale Peter Coviello, Senior Assistant Surgeon, U. S. Public Health Service Reserve, North Bergen, N. J.; Regia Università degli Studi di Bologna Facoltà di Medicina e Chirurgia, Italy, 1941; served an internship and residency at St. Michael's Hospital in Newark, N. J.; commissioned on March 26, 1944 as an assistant surgeon in the U. S. Public Health Reserve; on May 4, 1946 promoted to senior assistant surgeon; assigned to coast guard; killed in a crash of an air transport command plane near Westover Field, Mass., July 9, 1946, aged 32, as he was returning to the United States for release from an overseas assignment with the U. S. Coast Guard.

The End of the Indian Medical Service

Under British rule European civilization has been introduced into India, and in this regard nothing has been more beneficent than the gift of Western medicine by the establishment of the Indian Medical Service. This began with the appointment in 1612 of John Woodall as the first surgeon general of the East India Company. The service was necessarily staffed by British officers until it was possible to train native ones. The termination of British rule has brought to an end this service, to which a tribute was paid in the Houses of Parliament by the Prime Minister and the Earl of Listowel. The latter moved in the House of Lords an appreciation of the work of the civil and military services. He said that the Indian Medical Service, though its primary function had been the care of the members of these services, had also contributed to the advance of medical science and had played a leading part in building up a modern system of applied medicine in India. Its research into the causation of malaria resulted in discoveries about the mosquito which enabled the Panama Canal to be built. In the application of medicine it reduced the death rate from cholera in India by two thirds, and in its mastery of the diagnosis and treatment of many tropical diseases it brought relief to thousands of victims. It was the pioneer, and for many years the only source, of medical education and the father of the three medical colleges which were founded in British India in the nineteenth century. As a result of this pioneer work India now possesses a well-organized medical profession of more than fifty thousand practitioners.

Penicillin and Other Antibiotics

The British Association for the Advancement of Science has resumed its annual meetings, which were interrupted by the war. At a joint meeting of the sections of chemistry and botany Sir Alexander Fleming, the discoverer of penicillin, opened a discussion on "Penicillin and Other Antibiotics." He defined an antibiotic as a substance produced by a living body which has a destructive or inhibitory effect on a micro-organism. Penicillin is not the first antibiotic used for the treatment of infections; instances of one microbe hindering the growth of another have been commonplace in bacteriology, and about fifty years ago a substance resulting from the growth of a bacterium was recommended for the treatment of diphtheria and other infections. However, the results were not dramatic and this substance disappeared. Penicillin has a powerful effect on some bacteria but is without action on others.

With regard to the administration of penicillin, Fleming pointed out that it is exceedingly diffusible and differs from the old antiseptics in that it is not poisonous to human cells. Penicillin is not readily or uniformly absorbed from the alimentary canal and so has to be given by injection. It rapidly gets into the circulatory system but is rapidly excreted by the kidney, the injections being repeated frequently. Much work is being done to obviate this disadvantage. Penicillin has to be used on the right microbes and administered in such a way that it reaches the infecting organisms in sufficient amount to kill them. It is no use to suck a few penicillin lozenges to cure a septic infection of the finger.

The success of penicillin had led workers all over the world to try to find a better antibiotic. It seems incredible that an agent whose discovery was due to a chance observation should be the best, but in spite of all the work which has been done penicillin remains supreme. The study of antibiotics is going to change medical treatment in many ways. What is possibly even more important than the effect of antibiotics on bacteria in the body is the discovery in these agents of new chemical linkages destructive to bacteria. With a knowledge of these linkages the chemist will doubtless be able to prepare modifications which have all the advantages and none of the disadvantages of the natural product.

Soils and Health

In the Agriculture Section Dr. W. G. Ogg in his presidential address reviewed present knowledge of the importance of soils to the health of plants, animals and human beings. One of the most interesting advances in the study of soil fertility has been the recognition of the part played by what are termed "the trace elements." In addition to the major plant foods—nitrogen, potassium, phosphorus and calcium—it is now known that traces of certain other elements are essential for normal health and growth. Up to the present this group of trace elements comprises boron, manganese, copper, zinc and molybdenum; all of which, except boron, are necessary for animals. Cobalt and iodine, which do not seem necessary for plants, are nevertheless required by animals. Little is known about how the trace elements act—what role they play in plant and animal nutrition—but possibly they are catalysts. They must be present in soil in available forms, and it has been noted that too much may be as detrimental as too little. The discovery of trace elements has cleared up the problems of many plant and animal diseases.

It is of great importance to agriculture to have as much information as possible about the natural distribution and availability of the elements concerned with the nutrition and health of plants and animals. Developments in methods of quantitative spectrographic analysis, both roentgenologic and optical, have been of great value in obtaining the necessary analytic data; man's knowledge of the distribution of trace elements in the earth's crust has been revolutionized. Much still remains to be learned about mineral deficiencies and excesses. In most cases they do not seem to affect the health of human beings, because as a rule man's food is drawn from such wide sources that a deficiency in one article of diet would probably be made good in another that is drawn from a different region. Probably more can be done for the improvement of health in the world today by providing ample supplies of food than in any other way. The propagation of unfounded beliefs about the harmful effects of fertilizers is detrimental to the interests of the community.

The Immunization of Young Children Against Diphtheria

In 1941 the Ministry of Health launched a national campaign to immunize children against diphtheria before their first birthday. The slogan is: "Diphtheria costs lives—Immunization costs nothing." The result has been a remarkable progressive fall in the number of cases and the number of deaths. Prewar figures averaged 58,000 cases and 2,800 deaths annually. In 1941 these figures had fallen to 50,797 and 2,641. In the following years the fall has steadily continued, until in 1946 the figures were only 18,284 and 472. The figures mean that for every 6 children who died from diphtheria before the war only 1 died in 1946 and that the number of cases has fallen by 40,000. Last year half a millon children under 5 years of age were immunized. The aim this year is to immunize 590,000 babies before their first birthday. It is believed that such a high level of immunization has been achieved among children that diphtheria could be eliminated as an epidemic disease if in each year 3 of every 4 babies were protected before reaching their first birthday. The total number of children immunized since the campaign began is more than 6,600,000.

Kala-Azar in Turkey

Although malaria prevention and control work has been under way for twenty years, malaria remains the foremost public health problem in Turkey. The public is now taking blood examinations as a matter of course; exploratory punctures of enlarged spleens are made and lately also sternal punctures.

The first publications concerning kala-azar in Turkey came from Prof. Dr. Ihsan Hilmi Alantar of the Istanbul University, who in 1937 and 1938 diagnosed 7 cases at the Istanbul Children's Hospital. Four of the patients were living on the Bosporus coast, 2 in Istanbul and 1 on the coast of the sea of Marmora. None had gone anywhere else. All the patients had been suffering from fever occurring at irregular periods, weakness, anemia and at intervals diarrhea. All patients had hard enlarged spleens extending as far as the umbilicus and even to the hypogastrium, and livers extending 3 inches beyond the ribs. The patients belonged to lower middle class and poor families. Only 1 child had from time to time played with a neighbor's dog; the others had played in places or streets where stray dogs were about but never had any close contact with dogs.

A boy aged 5, born and brought up in a small town on the coast of the sea of Marmora, was admitted to the Children's Hospital in May 1938. He had had an elevation of temperature at irregular periods for three years, subnormal temperatures for the last five months, nosebleeds from time to time and swelling of the abdomen. The patient had had treatment for malaria for six weeks; the temperature had come down but the general condition had become worse and the abdomen had continued to swell. On admission the child weighed 14 Kg. and measured 103 cm., his face was pale, he was apathetic, and the spleen was hard and very large, blood count revealed 2½ million red corpuscles, 4,000 white corpuscles, hemoglobin 49 per cent, and the value of the globulin was 0.9. Leukocyte count revealed segmented forms 44 per cent, young forms 5, monocytes 9, lymphocytes 42, eosinophils 0, basophils 0. The formol-gel test was positive; also the Chopra-Gupta test. Exploratory puncture of the spleen revealed Leishmania and plasmodia; sternal puncture Leishmania. While the child was under treatment with neostibosan it developed measles and died. The spleen and sternal punctures of the other 6 patients also revealed Leishmania donovani. The formol-gel test in the third, sixth and seventh cases was negative, the Chopra-Gupta test negative only in the sixth and seventh cases. All seven cases proved to be visceral leishmaniasis.

Bacteriologist and malarialogist Dr. Seyfeddin Okan, director general of the malaria prevention and control department of the Ministry of Health, diagnosed 23 cases of kala-azar through finding in the spleen and by sternal puncture Leishmania organisms in abundance. The formol-gel test was positive in all cases, the Chopra-Gupta test in only 17 cases; it was negative in 6 cases. The neostibosan treatment was successful except in 1 case. These patients, aged 1 to 16, were born and had always lived in Adana, Mersina and the environs except for 1 who had come from Hatay. None had had any contact with dogs. Most of these children had in the beginning been treated for malaria, were weak and anemic, and had enlarged spleens and livers. This makes it evident that on the Turkish coastal regions of the Mediterranean and the Aegean isolated instances of kala-azar exist, mostly in children and adults below the age of 20.

Although since then in the Istanbul, Smyrna, Ankara and Bursa general hospitals Leishmania organisms have been looked for in patients with enlarged spleens, they are rarely encountered. So far only 36 cases of kala-azar have been mentioned in Turkish medical literature. The last 3 cases were again found in the Marmora coastal region and at the Bursa General Hospital they were presented to the Bursa medical society. It was said that the Bursa climate is favorable to Leishmania. Here is a short history of 1 of the cases coming under observation at the Bursa General Hospital:

A youth aged 18, a native of Uzunköprü, Turkish Thrace, came to Bursa when 9 years old and has been nowhere else. He began to have chills and a fever in March 1946. Believing he had malaria, he took quinine and quinacrine. The fever continued, bloody diarrhea, abdominal pain and increasing weakness forcing him to consult a physician. The patient was pale, weak and emaciated, the abdomen was unusually swollen, the liver extended 1 inch below the ribs, and the spleen filled the left inguinal region and felt extremely hard. Lymph nodules the size of lentils and peas were present in the groins, armpits, neck and inner elbow joints. One month after the onset of the disease, when iodine was applied to the skin for blood examination, erythema and itching revealed iodine idiosyncrasy. Laboratory examination revealed normal urine. Blood coagulation occurred in six to twenty minutes. Duration of flow of blood was one to four minutes. Thrombocytes numbered 66,000, red corpuscles 2,800,000, white corpuscles 3,000. Sedimentation during the first hour was 140 mm. Monocytes numbered 12 per cent, lymphocytes 20 per cent, young neutrophils 4 per cent, segmented forms 50 per cent, stab forms 13 per cent, eosinophils 0, reticulocytes 1. The formol-gel test was positive within two minutes, the Ray test positive. Spleen puncture revealed Leishman-Donovan bodies in abundance on Giemsa prepared slides.

A dog which had been the patient's pet for three and a half years was often afflicted with scabies and her offspring were either born dead or died within a week. The dog had purulent, bleary eyes and keratitis. She had lost all her hair and had several superficial ulcerations. The liver and spleen were enlarged. Puncture of the spleen was made four times and of the liver twelve times. In the spleen smear were found in cultures the same Leishmania organisms as in the patient; in the liver none were found. Fleas were taken from the dog and crushed, but the preparations did not reveal any parasites, nor were ticks found on the dog.

Preparations of antimony were unobtainable. High dosage of penicillin lessened the fever and the general condition improved somewhat, but improvement was not considerable. Injections with neostibosan, procured with great difficulty, brought about excellent results. After ninety-five days of treatment the lymph nodes had almost disappeared, there was no fever, the spleen had receded to the umbilicus and the patient had gained weight. Sternal and spleen preparations still contained parasites. Neostibosan was again procured and after twelve 0.3 Gm. injections every other day parasites were no longer found in sternal and spleen preparations, but the formol-gel test was still very positive, and sedimentation 125 mm. The painful bloody, mucous diarrhea from which the patient had suffered from the onset of the disease was cured with ultraguanidine. Points of special interest are that the patient was an adult, the lymph nodules seen in children were enlarged, high dosage of penicillin failed to bring about satisfactory results, the patient had an idiosyncrasy to iodine, the patient developed a cough after neostibosan injections, and the colic symptoms disappeared after ultraguanidine treatment. The most noteworthy point of interest is the fact that the patient had very close contact with his dog; they used to sleep out in the garden during the summer, with the dog close to him. The parasites found in the patient and the dog were of the same size. Generally speaking, Turkish people have no great love for dogs, considering them unclean; their religion forbids contact with stray dogs, probably because of the danger of contracting rabies. Shepherd and orchard dogs are a special race and are well cared for.

To spread knowledge concerning the prevention of kala-azar in Turkey, to facilitate its early diagnosis, give information in regard to treatment and point the way to investigation, the Ministry of Health asked the late Dr. Server Kamil, professor of hygiene at the Istanbul University Medical School, to write a monograph on the subject. This fifty-four page monograph was published in 1934 by the Ministry of Health and distributed free of charge to all health organizations and institutions concerned.

To sum up, sporadic cases of kala-azar, though not numerous, are found in Turkey. The disease occurs in children and young adults under 25 years of age. The cases that have been observed have all come from the coastal regions of the sea of Marmora, the Aegean sea and the Mediterranean.

Tumors of the Eye in Turkey

Before the Turkish Medical Society of Istanbul Dr. Nuri Fehmi Ayberk reported his experience as an eye specialist to the Haidar Pasha Model Hospital. He discussed at length 27 eye tumors encountered among the 70,000 eye patients he examined during the last ten years. There were 13 epitheliomas of the eyelids, 8 in men and 5 in women between the ages of 40 and 70. In these cases 60 per cent of the tumors were located at the inner angle of the eyelid. Dr. Ayberk attributed this location to age and occupation, advanced age causing relaxation of the orbicularis and eversion of the lacrimal point and the occupation of farming engaged in by the majority of these cases leading to chronic conjunctivitis due to exposure of the eyes to strong sunlight and dust. These causes give rise to continuous lacrimation, causing irritation of the skin and obliging the patient to wipe the affected region often, thus facilitating the development of the tumor. Of the tumors of the conjunctiva one was a papilloma originating at the upper eyelid; the other, resembling a melanosarcoma, proved to be a benign tumor originating at the lacrimal caruncle. Dr. Ayberk saw 7 carcinomas of the eyeball. There were 3 internal tumors of the eye, 1 primary sarcoma of the choroid and 2 gliomas. Among the tumors of the orbit there were 1 osteoma and 1 benign tumor of the optic nerve. In conclusion Dr. Ayberk said he had not seen any tumors caused by parasites.

Dementia Paralytica Treated with Penicillin

According to a communication to the Society of Neurology and Psychiatry of the Argentine Medical Association, Prof. Dr. Roque Orlando, director of the neuropsychiatric service and the center for malaria therapy of the Hospicio de las Mercedes of Buenos Aires and his collaborator Dr. M. Arndt treated within one year (August 1945-August 1946) 63 patients with penicillin; most of them had dementia paralytica, only 6 syphilis or other forms of neurosyphilis. They administered 2,000,000 Oxford units in doses of 20,000 each every three hours, intramuscularly. The temperature rose in some cases during the first days to 39 and 40 C. for various hours. Other manifestations or complications have not been observed. Five patients died after this treatment but for other causes (current complications of the disease).

Although the time of observation is still too short for definite conclusions, the authors are already able to confirm that the technic is easy and absolutely harmless. The results are considerable improvement in 10 of the 57 cases, a certain amount of improvement (although without important progress) in 11 cases, transitory improvement in 8 cases, no modifications in 15 cases; getting worse 3 cases; 4 died without modifications, and from 6 patients follow-up results were not obtainable. The improvement has been observed immediately after the completion of treatment or only several weeks or months afterward. The good results have been observed in initial cases or during the acute period, when they showed great excitation, euphoria, megalomania and the like but also in some advanced cases. In a large portion of these cases the psychotic symptoms disappeared completely. In 21 of 51 patients the cerebrospinal fluid showed favorable modifications of the inflammatory part of the paralysis, similar to the reaction after malaria therapy, but no important changes in the Wassermann or the Lange test. The results of penicillin therapy seem inferior to those after malaria therapy. It seems convenient to use both methods, administrating first 2,000,000 units of penicillin intramuscularly and then malaria therapy. It is possible that 2,000,000 units of penicillin is not sufficient; therefore a new series with 4,000,000 has been initiated.

Prenatal Tuberculosis

Until the investigations about to be described had been made, only isolated cases of prenatal tuberculosis had been known. The author who had reported the most cases was Ariztía of Santiago de Chile. No other author had reported more than 3 cases, and most authors only 1 case. Till now there has been only one review of the pathologic anatomy of this subject, by Morris Siegel of Chicago, but not one concerning the clinical aspect.

Drs. Carlos A. Urquijo and Ramón I. Latienda of Buenos Aires (Hospital Tornú) have made a thorough investigation of this question. It is the first study which describes particularly the symptomatology of prenatal tuberculosis. They observed 19 cases, 18 of them in mothers with serious tuberculosis who died in childbed. The majority of the children had a weight at birth of less than 2,800 Gm. The tuberculin reactions are mostly negative in these children, probably because of the high hydrophilia of the skin of the newborn.

The 19 cases of transplacental transmission of tuberculosis can be classified thus: among 156 children born prematurely of seriously ill mothers, 15 (9.7 per cent); among 62 children born at term of seriously ill mothers, 3 (4.8 per cent); among 1,008 children born at term of seriously or not seriously ill mothers, 1 (0.1 per cent) (very seriously ill means mothers who died from tuberculosis within sixty days after childbirth).

In their investigations, which are yet unpublished but for which they received the Juan Carlos Navarre prize of the National Academy of Medicine of Buenos Aires, the authors conclude that when a child has been born from a gravely tuberculous mother who has died in childbed, and particularly in the case of a prematurely born child we have to bear in mind the diagnosis of prenatal tuberculosis if the following syndrome is present even if it is incomplete: (*a*) a rather long asymptomatic period, without fever, and with progressive loss of weight; (*b*) later on, diminution of weight and irregular fever; (*c*) "cough without coryza," an essentially important symptom; (*d*) hepatosplenomegaly; (*e*) spherical abdomen and vicarious thoracoepigastric circulation (medusa head); (*f*) anorexia. If these symptoms are present almost constantly from 1½ months of age, they permit at least the presumptive diagnosis of prenatal tuberculosis even if the tuberculin reaction is negative and the x-ray appearance normal.

The relative frequency of the diverse primary localizations of prenatal tuberculosis has been in 98 cases, i. e. 19 of the authors' and 79 found in the literature: (*a*) lungs, (*b*) liver, (*c*) both of these, (*d*) others (intestine, ear). The organs most affected are the lungs, spleen, liver, intestine, kidneys, diaphragm, thyroid, skin, adrenals, stomach, tonsils, meninges, pancreas, heart, bone tissue, testicles and ear.

The most frequent lesions are macronodular, micronodular, miliary and submiliary in the liver, spleen and lungs, in the latter with or without a cavity; ulcerations and follicular reactions in the intestine; pseudofollicular ulcerations in the stomach; miliary and submiliary lesions in the rest of the organs. The only striking fact which differentiates the anatomic picture of prenatal tuberculosis from the other forms of generalized tuberculosis of the nursling is the high proportion of caseous adenopathy of the hepatic hilus.

Further Results with the Test of Galli-Mainini

Dr. Galli-Mainini's new test for determining pregnancy (The Journal, August 2, p. 1196) differs from other methods through its high (probably maximum) specificity, maximum rapidity, maximum simplicity of technic, minimum cost and *elimination of every subjective factor of interpretation.* The great advantages of this new method have been confirmed by 150 observations made by Drs. Pedro Figueroa Casas, Luciano Belizan and Juan J. Staffieri of the department of gynecology, department of endocrine diseases at the Italian Hospital at Rosario. In 99 of 100 cases of pregnancy the reaction was positive; in the 100th case it was negative, but the Friedman test was positive (while in another case the Friedman test was negative and the Galli-Mainini positive). In 2 cases of threatened abortion the Galli-Mainini test was positive, but negative in 2 cases of incomplete and 1 of complete abortion. One of the cases is particularly interesting: after fifteen days of amenorrhea the test was positive but after two months negative, and a few days afterward abortion occurred. The earliest date for the test is seven days of amenorrhea, but sometimes only the tenth or twelfth day. Earlier cases have not been observed by these authors.

The observations have been made during fall, with a temperature of 15 to 20 C. When it became colder, the animals did not react with the same activity, and reactions became negative; but afterward they were again positive when the toads d been put in tepid water and brought to warmer places. The st time for making the test is three hours after the injection f the urine, but it is already positive in 95 per cent after two hours.

The test was negative in 39 other cases of gynecologic trouble, the menopause and other conditions; also in 6 men.

Treatment of Chronic Nephritis with Testosterone

Drs. R. Q. Pasqualini and A. Imbriano have treated 1 case of subacute nephritis and 1 of chronic nephritis with prolonged administration of testosterone. In the first case this treatment was begun three months after the appearance of symptoms of hypertensive encephalopathy, and 900 mg. was administered in eleven weeks. In the second case treatment was begun fourteen months after the first symptoms, and 675 mg. was administered in eleven weeks. Both patients tolerated this procedure well with favorable effect, more apparent in the subacute case; in the second patient the proteinuria and uremia continued, although in lesser degree. The effect was particularly accentuated in the function of tubular resorption. Thus, the tubular activity becomes intensified and is able to regenerate, at least in part, its function, although the glomerular symptoms cannot be cured in all cases.

First Argentine Congress on Proctology

The first Argentine Congress on Proctology was held early in April at Buenos Aires. Well known Argentine and other South American specialists attended the meeting. Dr. J. Arnold Bargen of the Mayo Clinic was honorary president. The main official topic was ulcerative colitis. Drs. Carlos M. Barzizza, Andrés Bianchi, Carlos Bonorino Udaondo and Pedro A. Maissa were respectively speakers on microbiology, pathologic anatomy and general and roentgen pathology of the disease. Drs. Manuel M. Ramos Mejia, Oscar E. Napp and Norberto Stapler were respectively speakers on medical, surgical and dietetic treatment of the disease. The National Academy of Medicine had an extraordinary session to honor Dr. Bargen, who spoke in this session on "Origin and Development of Cancer of the Intestine."

Chronic Myocarditis in Chagas's Disease

Dr. C. Romaña of Tucumán carried on histopathologic studies in a case of chronic myocarditis caused by Chagas's disease, in which the characteristic lesions of the process were found in the heart. The case had been diagnosed clinically during life. Nests of Trypanosoma cruzi were found in the heart by postmortem studies, which finding was a proof of the origin of the disease. This is the first case of chronic myocarditis caused by the organism of Chagas's disease ever reported in Argentina in which the parasite of the disease was found in the heart.

The Value of Streptomycin

The Department of Public Health of the Argentine Republic has published a communication to the effect that streptomycin is a very efficient medicament for certain infectious diseases, but that its action is practically nil in pulmonary tuberculosis, and that for the time being it is preferably to treat this disease with the classic methods. *Owing to the very small quantity of* streptomycin available in the country, it must be reserved for diseases in which its effect is certain.

Crusade Against Cancer

A regional institute of new growths has been opened at Tucumán. There are available 350,000 Argentine pesos for habilitation of the institute, 55,200 pesos for salaries and 74,800 pesos for other expenses. In the northern region of Argentina there is no organization for patients with cancer. The patients are transported to Buenos Aires for roentgen treatment. Fifty per cent of patients with cancer in the northern region die without any medical care.

Brief News

Dr. Bernardo A. Houssay was appointed Doctor *Honoris Causa* by the faculty of Medicine of Geneva, Switzerland, when the faculty commemorated the seventieth anniversary of the foundation. Dr. Houssay was also appointed honorary member of the Academy of Medicine of New York.

Dr. Gregorio Aráoz Alfaro was recently appointed Professor *Honoris Causa* by the University of Rio de Janeiro.

A new medical magazine is being published in Buenos Aires: *Cirugia*, edited by a group of surgeons under the leadership of two prominent Argentine surgeons, the two Finochiettos. The well presented monthly is dedicated to all Latin American surgeons.

The professors ("titulares," i. e. who have a chair and are director of a clinic or an institute of the medical faculty) who had to retire or had retired a short time ago, have now been replaced. Dr. Tulio Martini has been appointed to the First Medical Clinic (chair of Professor Castex), Dr. Octavio M. Pico Estrada to the Second Medical Clinic (chair of Professor Romaño), Dr. Orestes E. Adorni for medical pathology, Marcial I. Quiroga for dermatology and syphilis, Dr. Carlos P. de Nicola for the Fourth Surgical Clinic (chair of Professor A. Ceballos), Dr. Anibal Ruiz Moreno for history of medicine (Professor Beltrán has now the chair of legal medicine instead of Professor Nerio Rojas, who retired), and Dr. Julio E. Bazán for obstetrics.

The Argentine branch of the National Gastroenterological Association elected Dr. Arturo Richieri president for the period 1947-1948.

An International Congress of Hospitals will be held at Buenos Aires in October. It is organized by the Asociación Argentina de Hospitales under the auspices of the Secretariat of Public Health.

INSTITUTE OF ANDEAN BIOLOGY FOR STUDY OF HIGH ALTITUDE PHYSIOLOGY

To the Editor:—The Institute of Andean Biology, a medical research institution chiefly devoted to the study of the effects of a high altitude environment on the human body, and which is affiliated with the Faculty of Medicine of the University of San Marcos (Lima, Peru), has under construction a new laboratory in Morococha, in the Andean zone. Funds have been raised to cover the total cost of the land and building.

This laboratory will occupy a land area of 335 square meters (400 square yards) with two floors, the first one will consist of an office, two large and four medium-sized laboratories, a dark room, a ward with three beds and sanitary services, a storeroom and an animal house. The second floor will include four bedrooms (each with a bathroom), for eight persons, a dining room (which will be also used as library and conference room), a pantry and a sleeping room for servants. The laboratory will be provided with heat, running cold and hot water and electricity (220 and 110 volts). Connected to this building is the medical department of a mining company, where x-ray facilities are available. Food may be obtained from this company.

Morococha, where the laboratory is being built, is a mining town with a permanent population of about 4,000 inhabitants, most of whom are of the Indian race; there are also a considerable number of white persons; its altitude is 4,540 meters (14,900 feet). It is located at 150 kilometers (93 miles) from Lima (at sea level), and this distance may be traveled by automobile on a good road in about three and a half hours. The average barometric pressure in Morococha is 430 mm. of mercury.

The road connecting Lima with this town goes through several small populated places, which are located at different altitudes, and 10 kilometers (6 miles) before it reaches Morococha it passes through a mining camp located at an altitude of 4,850 meters (15,920 feet). Forty kilometers (25 miles) from Morococha is Oroya, altitude 3,730 meters (12,230 feet), where a mining organization runs an eighty bed hospital provided with all modern facilities. Farther down on the eastern slope of the Andes the Institute of Andean Biology operates a laboratory in the city of Huancayo, of about 30,000 inhabitants and at an altitude of 3,100 meters (10,170 feet).

In Lima, at sea level, the institute has several physiologic, chemical and clinical laboratories provided with adequate equipment, mainly obtained through donations from American institutions, such as the Rockefeller Foundation. Most of the staff members have been trained in the United States on the basis of fellowship grants.

The location of the new high altitude laboratory in a town with a permanent population, also its short distance and easy access from sea level, will allow investigations concerning the effects of a low pressure environment on human beings and animals born and raised under such a condition and on newcomers. It will also be possible to carry out studies on men who arrive at sea level after a permanent or long residence at high altitudes; finally, additional observations may be made at different altitudes, in places which range from sea level up to 4,850 meters (15,920 feet), where obtained blood, air and other samples may be transported to the laboratories for analysis. Weather conditions allow continuous operation of and access to the high altitude laboratory throughout the whole year, although transportation is facilitated during the dry season (May to October).

The Institute of Andean Biology has already made some high altitude studies, some of them still under way, in the fields of respiration, circulation, hematology, metabolism, pharmacology, fertility, industrial hygiene (cases of silicosis and lead poisoning) and clinical illness (acute and chronic mountain sickness and so forth).

Considering the favorable opportunities which a laboratory of the characteristics just described will provide for the study of high altitudes and anoxic problems in general, the institute hopes that it may interest some of the American foundations and universities to establish a permanent connection with it, through a scientific and economic agreement which will permit its equipment and maintenance in such a way that these institutions may at any time send research workers, who will find constant facilities to carry out definite investigations, both at sea level and at high altitudes, either independently or in collaboration with the staff of the Institute of Andean Biology. Incidentally, it may be mentioned that Lima, and in consequence Morococha, are only twenty hours air travel distance from New York.

We hope to obtain American help in the project. We sincerely believe that it will serve not only to aid the organization of a high altitude laboratory, with facilities perhaps unique in the world for the study of the effects of a low pressure environment, but also to enlarge the friendly and scientific relations between the medical institutions of North and South America.

Carlos Monge, M.D.
Alberto Hurtado, M.D.

Lima, Peru.

THE PHYSICIANS FORUM, INC.

To the Editor:—In your editorial "Propaganda Activities of Government Agencies" appearing in The Journal, August 9, page 1240, you state that the Physicians Forum is "said to be a propaganda agency for the Wagner-Murray-Dingell Bill." You further quote the House committee as finding "that most of this literature, as distributed by . . . the Physicians Forum, originated in the Bureau of Research and Statistics of the Social Security Board. . . ."

The Journal has quoted the report of the Committee on Expenditures in the Executive Departments and therefore cannot be accused of originating these statements. The fact remains, however, that both these statements are incorrect, and the committee is completely in error in its findings.

The Physicians Forum was founded before the introduction of the first Wagner-Murray-Dingell bill and is an organization of physicians interested in all phases of medical care. The Forum believes that national health insurance is the only ultimate solution for the problem of the proper distribution of adequate medical care and has publicly supported the Wagner-Murray-Dingell bill as one of its activities.

All the literature published by the Forum is and has always been prepared by physicians who are members of the organization. None of it was inspired by, none of it originated in, the Bureau of Research and Statistics of the Social Security Board.

This letter is sent to you for publication to correct the misinformation unwittingly spread in your editorial.

George D. Cannon, M.D., Secretary, New York.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Charitable Hospitals in Relation to Taxes for Workmen's Compensation.—This was an action to test the validity of an order of the Department of Labor and Industry made pursuant to a statutory enactment. From a decision holding the statute unconstitutional, the department appealed to the Supreme Court of Washington.

In 1945 (chapter 89, Laws 1945) the Washington legislature passed a law which provided:

> An Act giving workmen's compensation benefits to persons engaged in hazardous and extrahazardous occupations in charitable institutions. . . .
>
> Section 1. Every person employed in a hazardous and/or extrahazardous occupation by an individual, firm, association or corporation operating a charitable or nonprofit institution, enterprise, business or establishment. shall be entitled to the benefits of chapter 74, Laws of 1911, and all amendments thereto relating to compensation for injured workmen.

By way of explanation the Supreme Court said that it must be noted that, although the act does not in terms purport to amend any existing law, it (1) purports to extend the benefits of a series of former acts to workmen engaged in hazardous, as well as extrahazardous, occupations; (2) makes no attempt to define or distinguish between hazardous and extrahazardous occupations; and (3) gives notice in its title that it applies only to employees of "charitable institutions," but, in the body of the act, includes every person engaged in any hazardous or extrahazardous occupation "by an individual, firm, association or corporation operating a charitable or nonprofit institution, enterprise, business or establishment." After passage of this act, the administrative department charged with its enforcement issued the following order:

> To All Branch Offices:
>
> Every person employed in a hazardous and/or extrahazardous occupation by an individual, firm, association or corporation operating a charitable or nonprofit institution, enterprise, business or establishment shall be entitled to the benefits of Pierce's Perpetual Code 702 to 718, chapter 74, Laws of 1911, and all amendments thereto relating to compensation for injured workmen.
>
> The Department has decided to create a new class to include all of the new contributors created under this law. The new class is 60-2 and the 1945 rates will be $.004 per workmen hour for industrial insurance and $.002 per workman hour for medical aid. effective June 6, 1945. For your guidance we are listing a few answers to possible questions. (1) All employees of such organizations that receive remuneration in any form are to be included. (2) All employees, regardless of their duties, are to be reported under the one class. (3) Churches and church organizations are exempt. (4) The articles of incorporation or the by-laws of such organizations should be consulted to determine whether or not any organization is nonprofit. We suggest that you contact all such organizations in your district and attempt to have all of them reporting when the new law takes effect.

It will be noted, said the Supreme Court, that the order directs (1) that every employee of a charitable or nonprofit institution is to be included whether his work is hazardous or extrahazardous, and (2) that they are all placed in one class, and the same rate of contribution is provided as to all, this whether the individual workman operates a power buzz saw or a fountain pen. Furthermore, the court continued, although it is indisputable that a church is, as a matter of law, a charitable institution, it is ordered that "(3) churches and church organizations are exempt."

The first question to be determined by the court was whether chapter 89 was an amendment or a supplemental act. Assuming it to be an amendment, the court pointed out that the Washington constitution provides that "no act shall ever be revised or amended by mere reference to its title, but the act revised or the section amended shall be set forth at full length." The result desired by such a provision is to have in a section as amended a complete section, so that no further search will be required to determine the provisions of such section as amended. In chapter 89 there is no reference to any title in the statute, but, said the Supreme Court, it actually changes at least four of the basic paragraphs of the original act. Considered as an amendment, therefore, the act fails to comply with the constitutional requirement that the act revised or the section amended shall be set forth at full length.

The department, however, insisted that the act was a supplemental act and not an amendment. Supplemental legislation, said the Supreme Court, must be tested by answering the following question: Can a person of ordinary intelligence mistake its meaning? Can we know what the legislature intended without referring to any other act or statute? Counsel representing the department say in their final brief: "Chapter 89 is complete in itself, it has only one purpose and that purpose only to bring in the men and women who received pay from charitable institutions for working around machinery or as janitor or in hazardous occupations." The auditor of the department, however, testified as follows: "Q. Now Mr. Graves, you found no guide or standard in chapter 89, did you, that would serve as a standard or guide for you in fixing the classifications? A. None whatever. Q. Then you did the only thing you saw to do, is to turn to that section of the existing statute of the workmen's compensation act and try to apply the guide that you found there? A. That is correct." It is clear, said the court, that neither the department nor the members of this court can "know full well what the legislature intended without referring to any other act or statute."

We are further of the opinion, the Supreme Court concluded, that chapter 89 violates section 19 of article II of the constitution, which provides that "no bills shall embrace more than one subject, and that shall be expressed in the title." This provision or its equivalent is found in all or nearly all state constitutions. It is universally agreed that one of the principal objects of this constitutional provision is to fairly apprise the people, through such publication of legislative proceedings as is usually had, of the bills being considered, to the end that persons or institutions affected by such bills may have an opportunity of being heard thereon, by petition or otherwise, if they so desire. Such publication is usually, if not almost universally, made by publishing the titles. Clearly, the title to this bill is very restrictive. It gives notice of a proposed bill that affects "charitable institutions" only, and no other, but in the body of the act it is made applicable to nonprofit institutions as well. There is a wide distinction between charitable institutions and nonprofit institutions in the state.

The judgment of the trial court in holding the act to be unconstitutional was accordingly affirmed.—*Swedish Hospital v. Department of Labor and Industry, 176 P. (2d) 429 (Wash., 1947).*

Medical Examinations and Licensure

COMING EXAMINATIONS AND MEETINGS

BOARDS OF MEDICAL EXAMINERS
BOARDS OF EXAMINERS IN THE BASIC SCIENCES

Examinations of the boards of medical examiners and boards of examiners in the basic sciences were published in The Journal Oct. 4, page 307.

NATIONAL BOARD OF MEDICAL EXAMINERS

National Board of Medical Examiners: *Part III.* Durham, N. C., Oct. 21-23. Exec. Sec., Mr. Everett S. Elwood, 225 S. 15th St., Philadelphia 2.

EXAMINING BOARDS IN SPECIALTIES

American Board of Neurological Surgery: *Oral.* Chicago, May or June. Final date for filing application is Feb. 1. Sec., Dr. W. J. German, 310 Cedar St., New Haven, Conn.

American Board of Obstetrics and Gynecology: *Part I. Written.* Various Centers, Feb. 6. Final date for filing application is Nov. 1 Sec., Dr. Paul Titus, 1015 Highland Bldg., Pittsburgh 6.

American Board of Ophthalmology: Chicago, Oct. 6-12. Sec., Dr. S. Judd Beach, 704 Congress St., Portland, Me.

American Board of Orthopaedic Surgery: *Part I.* April-May. Applications are accepted for the next examination until Jan. 15, 1948.

American Board of Pediatrics: Dallas, Dec. 5-7. Philadelphia, Jan 9-11. Sec., Dr. Lee F. Hill, 718 Royal Union Bldg., Des Moines 9.

American Board of Plastic Surgery: Examinations are given in April and November of each year in the home town of applicants. Sec., Dr. Robert H. Ivy, 1930 Chestnut St., Philadelphia.

American Board of Psychiatry and Neurology: *Oral.* May 1948. Final date for filing application is Feb. 15. Sec., Dr. F. J. Braceland, 102-110 Second Ave., S.W., Rochester, Minn.

American Board of Radiology: *Oral.* Chicago, June 1948. Final date for filing application is March 1. Sec., Dr. B. R. Kirklin, 102-110 Second Ave., S.W., Rochester, Minn.

American Board of Surgery: *Written.* Various Centers, March. Final date for filing application is Dec. 1. Sec., Dr. J. S. Rodman, 225 S. 15th St., Philadelphia 2.

American Board of Urology: Chicago, February. Final date for filing application is Nov. 1. Sec., Dr. Harry Culver, 1409 Willow St., Minneapolis 4.

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1937 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied with stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Diagnosis of Tricuspid Valve Disease. S. Aceves and R. Carral.—p. 114.

Tobacco Angina.—Bryant and Wood investigated the effect of smoking on the electrocardiograms of 16 patients with coronary disease. All the patients had smoked for a long time, but the majority should probably be considered moderate rather than heavy smokers. The diagnosis of coronary disease was made on the basis of a history typical of angina pectoris, abnormal electrocardiographic findings at rest or abnormal electrocardiographic changes precipitated by exercise. In 2 instances diagnosis of recent anterior myocardial infarction was made on the basis of diagnostic changes in the precordial electrocardiogram. After the patient had rested in the recumbent posture for a time sufficient to give a basal heart rate, a control electrocardiogram was taken. Immediately afterward the patient smoked two cigarets of the brand to which he was accustomed. A second electrocardiogram was taken about ten minutes later when he had finished smoking or sooner if he experienced discomfort in the chest. One instance of pure tobacco angina was discovered. In another instance the pain was precipitated by exertion and by tobacco. Neither patient had suspected that his symptoms were related to smoking. Minor changes in the T wave induced by smoking usually represent a physiologic response to an increase in the heart rate and not to myocardial ischemia. This phenomenon occurs in patients with angina pectoris as well as in normal subjects but is not associated with anginal pain. The cardiovascular effects of tobacco smoking vary greatly from person to person and in the same person from time to time. It is possible that the use of tobacco plays a more important role in determining the symptoms of coronary disease than has been realized in the past.

Circulatory Adaptations in Ayerza's Syndrome (Black Cardiacs).—According to Taquini and his associates, clinical and anatomic studies have led to the conclusion that Ayerza's disease is a form of chronic cor pulmonale with cyanosis. Sclerosis of the pulmonary artery, which has been considered very important, is actually only secondary to the chronic bronchopulmonary disturbances that determine the disease. Studies made on 16 patients with Ayerza's syndrome enabled the authors to demonstrate the existence in all patients of alveolar hypoventilation, diminution of oxygen tension in the arterial blood, increase of the carbon dioxide tension, diminution of p_H, hemoglobin increase, increase of blood volume and increase of the circulation time. Alveolar hypoventilation, as well as inadequate distribution of gases in the lungs, easily explains the anoxemia observed in most of the patients studied. Anoxemia was also fundamental in producing an increase in hemoglobin and blood volume. Increase of hemoglobin held the amount of oxygen in the blood in quantities near normal, even though a definite decrease of oxygen tension existed. Although blood velocity was decreased, an increase in blood volume permitted normal arteriovenous difference and cardiac output. Decrease in blood velocity and increase in the volume of the vascular bed in patients with Ayerza's syndrome explain how the heart can maintain normal minute output and arterial blood pressure within normal limits in spite of the presence of a decided increase in the viscosity of the blood.

Effects of Intravenous Injection of Nicotine on the Circulation.—Boyle and his associates gave intravenous injections of 2 mg. of nicotine bitartrate to 46 subjects. These included 18 normal persons, 24 patients with coronary heart disease and 4 with peripheral vascular disease. Observations were made on changes in the heart rate, blood pressure, cardiac output and electrocardiogram. The amount of nicotine alkaloid contained in 2 mg. of the bitartrate is approximately 0.6 milligram. This corresponds to the estimated amount of nicotine absorbed on inhaling the smoke of a cigaret five times in the course of one minute. A comparison was made of the average changes observed in heart rate, blood pressure and cardiac output, but no significant differences between the three groups were apparent. There was much less variation in repeated tests on the same person than on different persons. There were no significant differences in reaction between smokers and nonsmokers. After the injection of nicotine, slight changes in the electrocardiogram were observed in some members of all groups. Significant changes were observed in 4 patients with coronary heart disease. In 2 of these, who suffered from spontaneous anginal attacks, pain was associated with the appearance of electrocardiographic changes. In all groups individual differences in sensitivity to nicotine were evident in the number and severity of the symptoms that followed its injection. The most frequent complaint was dizziness. Other symptoms were tingling, faintness and nausea. Vomiting and brief circulatory collapse occurred in one normal young man who had never smoked. Variation in the effects of nicotine on the circulation is as great in patients with cardiovascular disorders as in normal persons. This variation depends to a greater extent on individual susceptibility than on the presence of disease. In some patients with coronary heart disease the injection of nicotine induces a state of coronary insufficiency. This may be the result of constricting the coronary arteries or of increasing the work of the heart. Probably both mechanisms are concerned.

Fractional Circulation Times as Revealed by Fluorescent Tracer Substances.—According to Winsor and his associates the study of vascular dynamics has been facilitated by the newer tracer methods. They demonstrate the use of riboflavin as a fluorescent tracer substance. The technic employed was to raise a histamine wheal on various portions of the body to which the circulation time was to be measured. The volar surface of the forearm near the antecubital fold was used for arm to arm times and the dorsum of the foot was used for arm to foot times. During the developing phase of the wheal a fluorescent material was injected into an antecubital vein. The time was measured from the beginning of the injection to the first appearance of yellow-green fluorescence in the periphery of the wheal. Fluorescence was excited by a 100 watt CH-4 spot ultraviolet lamp fitted with a Corning 586 filter with maximal emission at 3,600 angstrom units. Riboflavin is a useful fluorescent tracer substance of particular value in determining the circulation times in infants and children. Properly controlled circulation times to the foot are, under certain circumstances, a more sensitive measure of congestive heart failure than are measurements made to shorter segments of the cardiovascular system. Fractional circulation times are useful in comparing circulatory dynamics in various regions of the body and are an aid in the diagnosis of certain cardiovascular states.

Total Hysterectomy.—Munnell says that the chief argument against total hysterectomy as a routine procedure has been that the operative mortality and postoperative morbidity rates are higher with total than with subtotal hysterectomy. In the eleven year period ended May 31, 1946 1,798 hysterectomies were performed in the gynecologic service of Bellevue Hospital. Of this number 1,583 were subtotal hysterectomies and 215 were total hysterectomies. Of these 215, over one half were performed in the last three years of the eleven year period. The mortality rate for total hysterectomy is higher than for subtotal hysterectomy in this series of 215 total hysterectomies. Increased skill from doing more and more total hysterectomies well as proper selection of cases should reduce the mortality in total hysterectomy. Increased mortality is the only valid objection to the procedure, and even this is not a tenable argument when the number of deaths from the possibility of cancer developing in the residual cervical stump are taken into account. The prevention of cancer of the cervical stump is an adequate reason for performing total hysterectomy in benign cases as long as the operation does not introduce an element of extra danger to the patient. As far as postoperative reaction is concerned, patients having had total hysterectomies will run a slightly higher temperature for a longer time. Catheterization is slightly less frequent in total than in subtotal hysterectomy. Postoperative distention is approximately the same in the two groups. The only postoperative complication that can be considered a valid objection is the possibility of injury to the bladder and/or ureters; proper technic should avoid this complication as well as that of prolapse or shortening of the vaginal vault. Sexual response in women following hysterectomy is not significantly different with the cervical stump remaining than with the cervix removed.

Toxemia of Pregnancy as an Allergic Reaction.—Lin says that a condition closely simulating toxemia of pregnancy with albuminuria, hypertension and edema was produced in rats by sensitizing them against placenta protein before they became pregnant. The most important pathologic lesions were found in the arterioles. The walls became greatly thickened and the vascular lumen correspondingly narrowed. There was some thickening of the basement membrane of Bowman's capsules as well as ischemia of the glomerular tufts. This corresponds closely to the early lesions in human toxemia of pregnancy. Wong and Pillot have reported that the earliest sign of toxemia of pregnancy is spasm of the arteriolar wall and the narrowing of its lumen, which can be observed in the eyegrounds. The findings in this preliminary experiment suggest that toxemia of pregnancy might be an allergic reaction of patients to the placental proteins.

Scleral Necrosis in Periarteritis Nodosa.—Harbert and McPherson report that a man aged 31, in whom scleral necrosis was associated with periarteritis nodosa, two years previously had had what was thought to be an allergic reaction to sulfonamides which were given in the treatment of otitis media and abscess of the nasal system. The eye lesion developed some time after a dacryocystectomy with excision of the fistulous tract as a preliminary to rhinoplasty. In the seventh week of the ocular disease it was thought advisable to perform a muscle biopsy to exclude periarteritis nodosa. The findings were consistent with those occurring in periarteritis nodosa. No treatment was of any avail. The patient was discharged from the hospital at his own request fifteen weeks after the onset of the ocular disease. A clinically similar type of ocular lesion has been described as anterior metastatic scleritis. The fundamental pathologic change in periarteritis nodosa is inflammation of the medium and small arteries, with fibrinoid hyaline necrosis and exudative processes. As the necrotizing process subsides in one organ it may involve another. Many etiologic explanations have been suggested, but the one most widely accepted is that it is not a disease entity but a hypersensitivity of the arterial walls. It is most often related to a bacterial allergy, but experimental evidence indicates that drugs, foreign proteins and serums, and even foods or pollens may be responsible. The number of cases has increased since the widespread use of sulfonamides.

Acclimatization to High Altitude.—Houston and Riley studied the respiratory and circulatory changes in 4 men exposed to gradually increasing simulated altitude. The data obtained strengthen the concept that acclimatization consists of a series of integrated adaptations which tend to restore the oxygen pressure of the tissues toward normal sea level values despite the lowered oxygen pressure of the atmosphere. The same pulmonary and circulatory changes which caused an increase in oxygen pressure necessarily caused a decrease in carbon dioxide pressure, and an initial effect of the decrease in carbon dioxide pressure was an increase in the alkalinity of the blood. Further changes occurred as acclimatization progressed to counteract this respiratory alkalosis. The fall in blood bicarbonate reflected the extent of these changes, which included a net increase in the other negative ions and probably a net decrease in the positive ions. These changes comprised secondary factors in acclimatization. There was no evidence that cellular metabolism decreased as part of the acclimatization process, since the oxygen consumption remained the same at altitude as at sea level, both during rest and during standard work. Since clinical evidence indicated that the subjects were moderately anoxic, it appears that cellular function was impaired by low oxygen pressure even though the amount of oxygen used by the cells remained normal.

Skin Temperature and Circulation in Decompression Sickness.—Tobias and his associates found that variation in circulation to the extremities is an important factor in the development of decompression sickness. The dorsal skin temperature of the hand of 24 subjects was measured during simulated ascents to 35,000 feet at room temperature. It was found that the mean temperature of subjects that did not develop decompression sickness remained relatively high and constant throughout the test. Those that developed bends pain had significantly lower hand temperatures prior to the onset of pain. The temperature dropped further after the pain appeared. Diathermy applied to the left knee significantly decreased the incidence and severity of symptoms in that knee and resulted in a slight general improvement of performance. Diathermy applied after onset of bends pain had no effect. Heated suits slightly reduced the incidence of severe bends.

Gastric Neurectomy for Ulcer.—Walters and his associates of the Mayo Clinic observed in more than 100 necropsies great variation in the distribution of the vagus nerves, which in the present study of their relation to the lower part of the stomach and esophagus they term "gastric nerves." In 92 per cent of the cases the nerves passed through the diaphragm as two distinct trunks. They are readily accessible for resection. The abdominal approach to the gastric nerves allows exploration of the abdominal contents and especially the ulcer, which is removed if it is a gastric ulcer and is suspected of being malignant, and a drainage operation of the stomach being performed if the duodenal ulcer is obstructive or likely to become obstructive. Resections of the vagus have been done at the Mayo Clinic in 66 peptic ulcers. Perforation of a duodenal ulcer and a subdiaphragmatic abscess caused the death of 1 patient fourteen days after gastric neurectomy and gastroenterostomy, and 2 other deaths occurred, 1 from a suspected cerebral embolism on the fourth postoperative day and the other at home from a heart lesion. This patient had had a gastrojejunocolic fistula closed and gastric neurectomy three months previously. In the other cases the immediate results, as evidenced by reduction in gastric acidity, gastric secretion, relief of gastrospasm and relief of pain, were good but not striking. If the good results will persist, resection of the vagus offers an easy and comparatively safe method of treating certain cases of peptic ulcer, especially the recurrent ulcers. Sufficient time must be allowed to pass to determine whether the good results are temporary or lasting and whether untoward results may develop.

Persistence of Symptoms Following Cholecystectomy.—Womack and Crider state that, when stones are present in the gallbladder and when the patient gives a history of typical biliary colic, one can usually anticipate a successful outcome of cholecystectomy. Relief of symptoms of cholecystitis in the stoneless gallbladder was in almost direct proportion to the damage to the gallbladder wall. The greatest relief of symptoms was obtained in patients with the gallbladder wall thickened by virtue of fibrous tissue, edema and cellular infiltration, whereas patients with relatively normal looking gallbladder walls were for the most part not relieved unless stones were present. Womack and Crider point out that the symptoms commonly observed in cholecystitis, such as pain, nausea, vomiting and dyspepsia, can best be explained on the basis of sympathetic and parasympathetic stimulation in the gallbladder region. Accordingly they concern themselves with the nature of the nerve supply to the bile passages and demonstrate pathologic lesions in these nerve pathways in patients with persistent symptoms following cholecystectomy. The presence of scar tissue around nerve trunks lowers the threshold of stimulation of nerve endings and nerve trunks. In order to prevent the postcholecystectomy symptoms, Womack and Crider whenever possible have separated the nerve trunks mesial to the common bile duct. In most instances this is fairly easily done if the peritoneum and underlying areolar tissue are removed from over the common bile duct before the gallbladder is resected. The nerve trunks can then be well visualized and lifted up with a blunt clamp and sectioned. At the same time the common bile duct is cleaned of all surrounding areolar and fibrous tissue. When such treatment of the common bile duct would be fraught with danger, the best treatment has been to strip the cystic duct of all its adjacent structures as well as the cystic artery. In this way none of the nerve fibers are caught in the ligature. A similar procedure is carried out on patients operated on for the so-called postcholecystectomy syndrome.

Changes in Kidneys of Rats with Hypertension.—Halpert and Grollman report studies on rats in which chronic hypertension had been induced by various methods. Chronic hypertension was produced in 15 rats by damage or elimination of renal parenchyma which reduced the number of available functioning nephrons. Such reduction was initiated when a figure of eight ligature was applied to one or both kidneys or when one kidney was removed without interference with the other. The chronic hypertension thus produced resulted in hypertrophy of the left cardiac ventricle, which paralleled the degree and the duration of the hypertension. These data indicate that neither damage of renal tissue, ischemia nor intrarenal vascular changes are primary prerequisites for the induction of hypertension but that it is the reduction of the total number of functioning nephrons which initiates the disorder. Hypertension once established caused further injury to the remaining nephrons whether one or both kidneys were present. Therefore, chronic hypertension of the rat is a progressive disease the advance of which can be retarded but not abolished.

Factor Promoting Leukocytosis in Inflammation.—Previously there was demonstrated in exudative material the presence of a factor capable of reasonably explaining the leukocytosis frequently accompanying inflammatory processes. This factor when injected into animals not only induces a discharge of immature granulocytes of the bone marrow but produces a hyperplasia or growth of granulocytes and of megakaryocytes in the marrow. Its activity in human beings suggests that the material may have a clinical application. The prognosis of many infectious processes is to a large extent referable to the number of circulating leukocytes. If, therefore, with a given local inflammation the leukocyte level could be raised, a tool would be available to reinforce antibiotics when dealing with some infectious processes. Menkin demonstrates that the leukocytosis promoting factor when injected into the blood stream of an animal with an already existing inflammation raises and maintains for a prolonged interval the number of circulating leukocytes. In such circumstances the leukocytosis is sustained for several days longer than when there is an inflammation alone or when the leukocytosis promoting factor is introduced without a concomitant inflammation. Some observations suggest also that this factor when injected several days prior to an acute inflammation of the pleura likewise tends to maintain a high leukocyte level in the blood for longer intervals.

Nodular Lesions of Muscles.—Clawson and his associates attempted to evaluate the significance of nodular polymyositis and degenerative lesions (atrophy, cytoplastic changes and nuclear variations) in 44 specimens of the deltoid muscle in cases of rheumatoid arthritis and in seven muscles from each of 450 routine necropsies. They conclude that nodular myositis and muscular degenerative lesions (atrophy and sarcoplastic and nuclear changes) are found commonly in rheumatoid and acute rheumatic arthritis and to a lesser extend in an ordinary series of necropsies. There appears to be some correlation between the inflammatory and degenerative lesions, but either may be present alone. The degenerative lesions occur more frequently than the inflammatory lesions. Nodular myositis is more commonly seen in biopsies of deltoid muscles in cases of known rheumatoid arthritis than in postmortem studies of deltoid muscles. The sexes are about equally involved. No particular type of disease except rheumatic fever and rheumatoid arthritis seems to increase the frequency of the inflammatory and degenerative lesions. The lesions are found more frequently in cases in which death occurred in the upper decades of life. It is doubtful whether the lesions can be considered as a specific reaction to the infective agent of either acute rheumatic arthritis or rheumatoid arthritis, but the lesions probably are a part of the rheumatic and the rheumatoid state.

Traumatic Rupture of Liver.—Wright and his associates report 32 cases of traumatic rupture of the liver without penetrating wounds observed at the Harlem Hospital. This lesion is not as rare as the scattered reports in the literature might indicate. The authors present a classification based on the rate of hemorrhage and remark that the abdominal tap is an invaluable aid as a diagnostic procedure. Associated lesions may mask signs and symptoms of ruptured liver. The treatment is surgical. The use of fibrin foam, oxidizable cellulose gauze or "gelfoam," which are the new methods for the control of hemorrhage, are worthy of extensive trial in these cases. Mortality can be reduced by early diagnosis and immediate operation, by free use of blood, plasma or other fluids to counteract hemorrhage and shock, by use of penicillin and sulfonamide compounds to prevent infection and by teamwork between the surgical and nursing staffs to maintain a close watch over the patient.

Partial Excision of Motor Cortex in Jacksonian Convulsions.—During the past ten years Pilcher has performed partial excision of the motor cortex on 41 patients with severe and frequent jacksonian convulsions but without space consuming or gross cicatricial lesions. No microscopic lesion was found in the tissue removed from 14 patients. Gliosis was present in the remainder. There were 2 operative deaths. Gradual return of motor function with little or no disability occurred in all but 4 patients who had moderate or severe hemiparesis. Eight patients were completely relieved of convulsions, 12 have shown pronounced improvement, 9 have been improved to a lesser degree, 8 have shown no improvement and 3 have subsequently died (1 of another cause). It is believed that partial excision of the motor cortex has a real value in selected cases with focal motor convulsions.

Perforative Appendicitis.—Jackson reports 15 cases of perforative appendicitis with peritonitis or abscess formation in which the appendix was removed, sulfathiazole was employed intraperitoneally, the incision was closed without drainage, and spinal anesthesia and early ambulation were practiced. There were no deaths. A secondary intraperitoneal abscess requiring drainage occurred in 1 case. There were no purulent wound infections or other complications. Penicillin was administered in the last 7 cases. A composite study of the opinions of 150 members of the Western Surgical Association on the problems of drainage and chemotherapy in perforative appendicitis is presented. This study shows that 81 members employ and 38 do not employ drainage, 18 rarely use a drain, 9 use drainage only if an abscess is present and 5 drain only to the peritoneal wall. Ninety use a sulfonamide drug intraperitoneally; 60 oppose its use. Only 13 use penicillin intraperitoneally, but 119 use it in other ways; 5 use streptomycin.

Plasma Albumin in Nephrotic Edema.—Roth states that plasma albumin infusions increased diuresis in 4 patients with a nephrotic syndrome. The mechanism cannot be entirely explained on colloid osmotic pressure changes, since diuresis took place even when the plasma protein levels were not greatly altered. Plasma albumin in amounts of 200 cc. daily was given for long periods to young patients without production of pulmonary edema or increased red blood cell fragility. Pulmonary edema due to increased plasma volume may occur in older people or in patients with cardiovascular disease. For that reason albumin should not be given at a rate faster than 5 cc. in one minute and under close observation. The lungs should be frequently examined for the appearance of pulmonary edema. Massive injections of plasma albumin failed to restore the normal plasma protein level. Since amigen alone resulted in practically no diuresis and no change in plasma protein level, it is probably of little value. Plasma albumin has the advantage over whole blood transfusions or plasma transfusions in that it rarely produces chills, fever, urticaria or homologous icterus. It contains less salt, and its colloid osmotic pressure is higher. The success of plasma albumin was proved in all 4 cases by causing diuresis and decreasing nephrotic edema. Success seems to be only temporary. The practical value of the treatment, because of its high cost, is its employment in cases which do not respond to other less expensive medications It can be used in emergency cases, such as intercurrent infections, severe ascites and pleural effusion due to nephrosis or chronic glomerulonephritis.

Para-Aminobenzoic Acid in Rocky Mountain Fever.—Best and his associates report the history of a woman aged 52 who had Rocky Mountain spotted fever and in whom they obtained satisfactory therapeutic results with para-aminobenzoic acid. On the first day of treatment a test dose of 200 mg. of para-aminobenzoic acid was given orally and was well tolerated. Following this 2 Gm. of enteric coated para-aminobenzoic acid, with 0.5 Gm. of sodium bicarbonate, was given every two hours orally, day and night. A blood level between 10 and 20 mg. per hundred cubic centimeters was maintained. The only toxic effects noted were nausea, mild leukopenia and transient glycosuria. The clinical response was excellent; the rash, headache and mental confusion were eliminated two days after treatment was begun. The temperature remained normal after three days of treatment. The medication with para-aminobenzoic acid was discontinued after seven days.

Hyperinsulinism of Menses.—Billig and Spaulding have observed in women a frequent and striking clinical syndrome consisting of a triad of symptoms: a burst of energy several days before the menses (premenstrual tension), easy bruising and general irritability (lowered threshold to pain). Practically all of them are somewhat irritable and hypersensitive. There is usually a history of recurrent complaints of peripheral radicular pains. Often patients with the syndrome are classified as psychoneurotic. While psychogenic factors may aggravate the condition and produce a vicious cycle in the untreated patient, neurotic manifestations usually clear up under treatment of the hyperinsulinism. The underlying cause for this syndrome appears to be an adrenal cortex deficiency, but it is felt that the ovary also assumes a significant role. Adequate relief from symptoms requires treatment with a carbohydrate free diet and adrenal cortex extract. Vitamin C may also be advisable in some cases. The diet prescribed, while low in carbohydrates, is high in proteins and fats.

Sensitization to Penicillin.—Hopkins and Lawrence paid special attention to cutaneous reactions during treatment of superficial infections with penicillin. The occurrence of reactions to treatment in the form of dermatitis in 9 per cent of the 618 patients treated and of positive reactions to patch tests in 13 per cent of the 318 cases tested after treatment shows that penicillin is an excellent sensitizing agent of the epidermis. In patients with eczematized lesions, sensitization was demonstrable in 27 per cent. Sensitization was often localized to limited areas of skin and was frequently transient. No severe generalized and completely disabling eruptions were encountered. Sensitization severe enough to prevent or prohibit systemic treatment with penicillin was encountered in less than 1 per cent of the cases.

Factors Affecting Dark Adaptation.—Rose and Schmidt studied the effects of caffeine-metrazol, muscular exercise, strychnine, ultrasonic vibrations, ephedrine, hydrochloride of isoamylamino-6-methyl 2 heptane (octin D), stimulation of taste with saccharin, and vitamin A in oil solution and in an emulsion on the dark adaptation in 15 normal persons. Using the nyktometer and the Engelking-Hartung adaptometer, no deviations were found which exceeded the calculated limits of error. When the results of the carefully made experiments were analyzed critically by the statistical method, none gave convincing evidence that night vision had been improved or impaired. No medications have been found to date which are any more effective than are normal diet and moderate living habits to get the best from night vision. No other methods which have been suggested can be supported by the evidence given.

Prolonged Hypoxia.—White studied the physiologic and psychologic responses of 7 men and 1 woman between the ages of 25 and 49 years who completed a circuit of the world by air in one hundred and forty-nine hours and thirty-eight minutes. One hundred and twenty hours and ten minutes were spent at altitudes principally of 9,000 feet except for periods over the Himalaya and Rocky mountains, when heights of 12,000 to ,000 feet were reached. Oxygen was used during these two periods. Ascents were made at a rate of approximately 900 feet per minute. No significant objective changes resulting from the cumulative hypoxia experienced at 9,000 feet were observed in the tests conducted. Subjectively headaches and fatigue were noted. Adequate sleep in a comfortable position relieved fatigue. It is concluded that normal persons can be exposed as passengers to long flights in modern passenger aircraft, flying at altitudes of 9,000 feet without deleterious results from a cumulative hypoxia. To prevent any ill effects on long flights, it is desirable for transport aircraft to be provided with pressurized cabins and sleeping accommodations for all passengers.

Metabolism of Single Therapeutic Doses of Natural Estrogens in Human Subjects. B. F. Stimmel.—p. 364.

Polyostotic Fibrous Dysplasia.—Albright describes a syndrome which in its complete form is characterized by a disseminated osteitis fibrosa (both hyperostotic and hypoostotic) with a segmental distribution, areas of cutaneous pigmentation which have a distribution suggesting some connection between them and the bone lesions, and sexual and somatic precocity when the condition occurs in the female. He believes this syndrome is not a form of lipoid granulomatosis (xanthomatosis) because the blood cholesterol level is not abnormal, the bone lesions show only a slight tendency to progress, clear up spontaneously, and are not radiosensitive. The segmental distribution of the bone and skin lesions is not suggestive of a metabolic disorder. The x-rays show increased bone formation as well as bone destruction; the areas of cutaneous pigmentation are not characteristic of lipoid granulomatosis. The serum phosphatase level is high when the disease is widespread and sexual precocity in females is not a feature of lipoid granulomatosis. Albright believes this syndrome is not a form of neurofibromatosis (von Recklinghausen) because he has never seen a case in which multiple cutaneous fibromas and widespread bone disease with evidence of increased as well as decreased bone formation were present in the same person; the syndrome does not tend to run in families; sexual precocity in females is not characteristic of neurofibromatosis. A necropsy by Dr. H. Edward MacMahon on a patient with the syndrome showed as a possible cause of the precocity not a tumor but a lesion in one mamillary body. Elephantiasis, so common in neurofibromatosis, has not been found in this syndrome. The condition had best be termed "polyostotic fibrous dysplasia," as suggested by Lichtenstein.

Syndrome of Rudimentary Ovaries.—Del Castillo and his associates of the Hospital Rivadavia in Buenos Aires say that two groups of American investigators, Varney and his collaborators and Albright and his co-workers, established the clinical and hormonal characteristics of a new syndrome based mainly on the application of certain biologic tests. The former authors called it "association of short stature, retarded sexual development and high urinary gonadotropin titers in women," the latter "a syndrome characterized by primary ovarian insufficiency and decreased stature." More cases with ovarian biopsies were presented by Wilkins and Fleischmann. These investigators called this condition "ovarian agenesis." Del Castillo and his co-workers report observations on 8 patients who presented the syndrome designated as rudimentary ovary with estrogenic insufficiency and increase in gonadotropins. The presence of rudimentary ovaries was demonstrated in 6 of these patients by microscopic studies of tissues removed during surgical exploration. With 1 exception all showed retardation of growth. Inadequate development of the sexual characteristics indicated estrogenic insufficiency, and the urinary gonadotropin titers were above normal in all these patients. In the cases in which rudimentary ovaries are associated with diminution in growth, differentiation from hypophysial dwarfism is especially difficult, but among differentiating characteristics they emphasize the presence of pubic and axillary hair and the increase in follicle stimulating hormone in the urine in those with rudimentary ovaries, whereas hypophysial dwarfism is characterized by lack of pubic and axillary hair and lack of follicle stimulating hormone.

Testosterone Propionate in Carcinoma of Breast.—Schwander and Marvin report observations on 5 women with carcinoma of the breast and metastases to the soft tissue and skeleton who were treated with testosterone propionate. Symptomatic relief of pain and increased sense of well being were pronounced following this treatment. Moderate doses of testosterone propionate have no beneficial effect on the primary tumor or soft tissue metastases. The results suggest that recalcification of osteolytic metastases occurs with adequate treatment. No serious side reactions were noticed with this method of treatment.

Rocky Mountain Spotted Fever.—Tichenor and his co-workers report the occurrence of Rocky Mountain spotted fever in 36 patients between the ages of 15 months and 13 years who were admitted to the Children's Hospital in Washington, D. C., between 1931 and 1946. Six of these patients were treated with para-aminobenzoic acid. Also 2 additional adults with the disease were treated with this drug. Powdered para-aminobenzoic acid was partially dissolved in 5 per cent sodium bicarbonate solution so that 15 cc. of the mixture contained 1 Gm. of the acid. This lessened the gastric irritation so that the drug was well tolerated. The degree of toxicity, duration of the disease and morbidity were favorably modified when compared with 30 patients not so treated. The mortality rate in the untreated group was 10 per cent, while there were no deaths in the 8 patients treated with para-aminobenzoic acid. Administration of 0.33 Gm. of para-aminobenzoic acid per pound of body weight in twenty-four hours in a three hour divided dosage schedule over a period of four days to 6 normal children in a preliminary control experiment suggested that para-aminobenzoic acid blood levels ranging between 15 and 36 per cent could be maintained with this dose. Daily prothrombin time determinations and cephalin flocculation tests showed changes suggestive of transient liver dysfunction. The carbon dioxide combining power was moderately reduced temporarily by the drug.

Effect of Tridione on Blood.—Davis and Lennox examined periodically the blood of 127 patients taking trimethyloxazolidine dione (tridione). The ages of the patients ranged from 8 months to 50 years. The only significant changes were a tendency to neutropenia or eosinophilia and a slight increase in lymphocytes. Definite neutropenia was present in 6.3 per cent of patients and borderline values in 7 per cent. In the remaining 87 per cent the number of neutrophils remained within normal limits. Repeated examinations indicate that the neutropenia is a gradual reaction. Monthly testing would seem sufficient to prevent the development of serious neutropenia. Tridione is a potent therapeutic agent and possible effect on the blood or on the bone marrow should not prevent its proper use. It should be used only when specifically indicated and under medical supervision. It should not be prescribed for patients with a history of blood dyscrasia and only cautiously for those with a history of idiosyncrasy to drugs. The blood should be examined monthly; patients with total neutrophil counts below 2,500 should be checked more frequently; if the neutrophil count goes below 1,600, treatment should be withheld.

Blalock-Taussig Operation.—The essential procedure of the Blalock-Taussig operation is the construction of an "artificial" ductus arteriosus. Salmon and Barkley performed the anastomosis in 8 of 10 patients between the ages of 3 and 11 years, in whom the chest was explored. Six of these were remarkably improved and are enjoying activity approaching that of a normal child. None have experienced a recurrence of the syncopal attacks, which were common before the operation. The average arterial oxygen saturation before operation was 56.4 per cent, after operation 80.1 per cent. The cyanosis of the lip improved either at the time of operation or in the immediate postoperative period. The cyanosis of the nail beds may require several days to improve. Since operation there has been a slight increase in heart size in some instances and little change in others. One of the 8 patients was neither improved nor apparently harmed; his preoperative pulmonary artery pressure was 340 mm. of water. One died twenty-four hours after the operation; the actual cause of death was not determined. One of 2 patients in whom anastomosis was not performed was discharged unharmed by the exploration, while the second suffered widespread central nervous system damage and died twenty-seven days later.

Homologous Serum Hepatitis Following Transfusion.—Bruyn reports the clinical and pathologic observations of an infant that died of homologous serum hepatitis when 15 weeks of age. This is believed to be the first report of such a case in this age group. Transmission apparently occurred through the medium of transfusions of whole blood given by 3 volunteer donors sixty to one hundred days before onset of the disease. None of them had ever had jaundice, nor had any of them been exposed to a known case of infectious hepatitis. Their histories were negative for virus pneumonia and infectious mononucleosis. These 3 donors represent an example of the unavoidable hazard in the problem of homologous serum hepatitis, i. e. the donor in whom the history is of no support in detecting the presence of hepatitis.

Cancer of Rectum.—This study is concerned with all cases in which a diagnosis of cancer of the rectum was made in the eleven year period from 1935 to 1945 inclusive. The patients were treated by many surgeons in both large and small hospitals. Complete follow-up data were obtained in over 97 per cent of cases. In the eleven year period 1,610 patients were admitted to hospitals with the diagnosis of cancer of the rectum. Information has been submitted to indicate the value of collecting cancer statistics on a statewide basis. Efforts must be made to reduce the time lag between the first symptom and definitive treatment. The signs and symptoms of cancer of the rectum are sufficiently striking to warrant early recognition. Biopsy should be performed for accurate appraisal. Operability and mortality rates are improving owing perhaps to the use of antibiotics in the prevention and treatment of sepsis, a better understanding of the management of shock and phlebitis and the more widespread employment of trained physician-anesthetists. Further improvement might be possible if some plan could be adopted of concentrating the care of these cases in a few centers. For the six year period 1935-1940 five year cures were obtained in only 7.9 per cent of all cases. A uniform method of reporting end results is highly desirable.

Infectious Hepatitis with Atrophy of Liver.—Jersild states that an unusual epidemic of infectious hepatitis has been present in Denmark since 1944. It differs from epidemics previously described in that the course has been extremely malignant. In a single department of a hospital 123 patients were treated for the disease. It is characterized by a protracted course (over three months) and by the occurrence of ascites and edema. Over 99 per cent of the patients were women. The mortality was 61 per cent. The disease chiefly affected women after the menopause, 79 per cent of patients being over 50 years of age. It is often characterized by a long preicteric phase—more than four weeks in 64 per cent—in contrast to acute infectious hepatitis, in which the preicteric phase in 92 per cent of patients was less than two weeks. The average duration of the disease in the fatal cases was nine months. The possibility of a special malignant virus is considered and the question is raised whether estrogens exert some form of liver-protecting influence against this infection.

Carcinoma and Hodgkin's Disease.—Skapier and Friedman observed 2 cases of Hodgkin's disease associated with mammary cancer. This concurrence is extremely rare, but there is no evidence that Hodgkin's disease has an anticarcinogenetic effect or vice versa in human beings. The rarity of the coexistence of the two diseases may be explained by the age incidence, by the duration and by the nature of Hodgkin's disease.

Tridione Therapy of Epileptic Patients.—Davidoff reports the results obtained with tridione in treating 42 epileptic patients at Craig Colony. About 50 per cent of the patients responded better to tridione than they did to previous drugs such as phenobarbital and/or diphenylhydantoin sodium. Tridione appears to be more effective in cerebral palsies or symptomatic epilepsies, particularly of children with milder types of organic impairment or milder seizures and when the manifestations are of more recent origin. It was of some value in about half the patients with psychomotor attacks and petit mal stupors; it appears to be of least value in grand mal seizures and long-standing myoclonias. Children and the milder cases responded better in all groups. Some of the favorable effects of tridione are counterbalanced by untoward reactions. It produces toxic reactions which necessitate careful observation of the patient preferably in a clinic or institutional regimen. Until the effects of tridione are better understood and its action more carefully established, tridione should be administered with considerable caution. Fewer toxic effects were noted in children.

Milk Sickness.—According to Doyle, milk sickness is an intoxication in human subjects caused by ingestion of milk and milk products of cows which have eaten white snakeroot (Eupatorium urticaefolium) or rayless goldenrod (Aplopappus heterophyllus). The primary intoxication in the animals is known as "trembles" or "split tail." Since Hardin's report in 1934, 21 additional cases of milk sickness have been seen in the author's region. Between 1941 and 1946 only 1 patient with acute milk sickness was seen, but in the past year 3 cases, including 1 fatal case, were seen. The disease is characterized by anorexia, weakness, fatigability, constipation, nausea and pernicious vomiting in acute, relapsing and probably chronic forms. The acute phase is characterized by profound dehydration and acidosis, and a fatal termination is common. Fever-

and leukocytosis do not occur. The toxic principle contained in white snakeroot and rayless goldenrod is a secondary alcohol called tremetol. Its mode of action is unknown. Treatment should be directed toward the correction of the dehydration and acidosis. Empirically the use of intoxicating doses of alcohol apparently improves the prognosis. Convalescence is prolonged, and relapse may follow premature physical exertion.

Recurrent Tubal Pregnancy. A. F. Lee p. 535.

Penicillin Resistant Streptococcus in Bacterial Endocarditis.—Scudder and Deputy's patient was a man aged 52 who twelve days before admission to their hospital in Seattle had developed an influenza-like disorder. At the time he first became ill he had been hospitalized in North Carolina and had been given 300,000 units of penicillin in twenty-four hours. After that his temperature became normal and he left the hospital contrary to the advice of his physician. At the end of a week he again developed chills and fever and was given 14 Gm. of sulfadiazine. After a three day remission he had another recurrence of chills and fever and was given another 200,000 units of penicillin. On the day prior to admission to the author's hospital he was given 300,000 units of penicillin in beeswax on account of a similar recurrence. On the day of admission to their hospital the blood cultures were sterile, but three subsequent cultures on three successive days showed profuse growth of B hemolytic streptococci. The temperature rose to 105.5 F. Penicillin in doses of 150,000 units every three hours was started again, but after three days of this treatment the status was about the same and chills and fever persisted. The patient was then placed on a regimen of continuous intravenous penicillin, 10 million units being given daily in 4 liters of fluid. He was given sulfadiazine in doses to obtain a blood level of 16 mg. per cubic centimeter. He was also given 15 Gm. of sodium bicarbonate daily. This treatment was given for seven days and then all treatment was discontinued, since the patient had been free from fever since the third day of the massive treatment. In all, the patient had received about 70 million units of penicillin. He was discharged on the twenty-eighth day and was apparently in good health six months later. The authors urge that bacterial sensitivity tests be repeated, because tolerance to penicillin may increase, and the determination of adequate doses of penicillin should be based on the sensitivity tests.

Clinical and Etiologic Studies in Hodgkin's Syndrome.—Hoster and his associates say that Hodgkin's syndrome continues to present the challenge of a disease entity occupying a position midway between the infectious granulomas of known etiology and the so-called true cancers of unknown cause. They review clinical and etiologic observations made in approximately 100 cases studied during the last four years. In support of the postulate that Hodgkin's disease may belong in the category of tumor-virus diseases, the following characteristics are cited: 1. The cellular lesion found in fixed tissue preparations of the pleomorphic or granulomatous type of Hodgkin's disease is not suggestive of neoplastic disease but of an infectious process. 2. The occasional spontaneous and complete disappearance of large lymph nodes without treatment, associated with the peculiar relapsing type of fever, tachycardia, pain and changes in hematologic equilibriums are suggestive of a chronic infectious process. There are no neoplastic diseases in which so many apparently dissimilar histologic variations, united only by the presence of small numbers of one type of cell (the Hodgkin cell) are classified under one name and for which there are a coexistent number of diverse clinical syndromes and organic manifestations. The behavior of explants of Hodgkin's tissue in tissue culture is grossly unlike that of tumor tissue in general: inclusion bodies, giant cell formation and cytostimulation are prominent. A similar cytopathologic reaction can be produced in certain normal cells in tissue culture inoculated with cell free Hodgkin's material. The authors also call attention to the clinical and histopathologic points of similarity between Hodgkin's disease in man and a tumor virus syndrome in chickens known as lymphomatosis, and a recently described, rare disease of unknown etiology designated as Hodgkin's disease of swine.

Untoward Effects of Thiamine or Niacin in Pernicious Anemia.—Farrar says that the similarities in the clinical features of pernicious anemia, pellagra, sprue and beriberi sometimes present difficulties in differential diagnosis. The demonstration of the therapeutic effect of folic acid in pernicious anemia, nutritional macrocytic anemia and sprue has added to the understanding of this relationship. In an effort to clarify this relationship, patients with the pernicious anemia symptom complex were treated with single factors of the vitamin B complex. Six cases are reported. It was found that when thiamine alone was administered to inadequately nourished patients with the pernicious anemia symptom complex glossitis became aggravated and diarrhea and pellagrous dermatitis developed. The erythrocyte count rose to normal levels in eight to twelve weeks without other treatment. Transient aggravation of peripheral neuropathy was observed following injections of thiamine. The manifestations of ariboflavinosis were observed when large doses of thiamine were combined with adequate doses of liver extract. The diet of these patients was persistently restricted by their "county relief" incomes, and it was high in carbohydrate. With a relatively adequate diet this pellagrous effect of thiamine was not encountered, and no rise in the blood hemoglobin or erythrocyte count occurred. Subsequently niacin was administered without other treatment to patients whose symptoms had been relieved and whose blood counts had been satisfactorily maintained with parenteral liver therapy. A drop in the red cell count occurred in four to eight weeks, with a recurrence of the symptoms of pernicious anemia. Relapse was much slower when liver therapy was omitted without the administration of niacin.

Sedimentation Rate in Myocardial Infarction.—Coronary occlusion with myocardial infarction has been recognized for some time as a cause for acceleration of the erythrocyte sedimentation rate. Koenig and Young investigated the sedimentation rate of 21 patients and report the histories of 6 of them. The cases illustrate the course of sedimentation curves taken at frequent intervals in cases of acute myocardial infarction of variable degrees. It appears that acceleration of sedimentation begins in the first hours after the thrombotic lesion occurs. While the acceleration may not be recognizable from a single observation, a series of daily curves for the first few days will readily demonstrate the presence of an acute catabolic process. The time for beginning of sedimentation is a valuable criterion of the activity of the process. The most rapid phase appears four or five days after the acute attack and is characterized not only by a fall of 20 or 25 mm. in an hour but by beginning of sedimentation in the second or even the first five minute period. A curve of equal depth which does not begin to fall until the third or fourth five minutes indicates either the preliminary acute phase or the beginning of improvement. Two of the cases indicate that definite acceleration may persist for periods of two to six months after the acute attack. It would seem reasonable to make beginning improvement in the sedimentation curve a prerequisite for allowing the patient to leave his bed. In such cases the potential dangers of too early activity outweigh those of peripheral phlebothrombosis.

Diethylstilbestrol in Prevention of Experimental Cinchophen Peptic Ulcer.—Nasio found that parenteral administration of cinchophen and of diethylstilbestrol propionate in dogs prevents appearance of the experimental cinchophen peptic ulcer in 100 per cent of the male dogs and in 22 per cent of the females. Most of the stomach of the experimental animals, particularly the male dogs, presented hyperplasia of the gastric mucosa. In 60 per cent of the females with cinchophen peptic ulcers the lesions were in the process of healing. In half of the animals receiving diethylstilbestrol alone the stomach seemed to be normal; in the other half a gastric hyperplasia and a congestive hemorrhagic gastritis could be seen. The difference in the prevention of cinchophen ulcers by means of diethylstilbestrol in female and male dogs may be explained by the lesser proliferative action of this estrogen on the gastric mucosa. The prevention of cinchophen ulcer with diethylstilbestrol may be the result of its epitheliotropic and vasodilating action, particularly its indirect effect of depression of the chlorhydropeptic activity.

Duodenal Ulcer in Identical Twins.—Robinson reports that 2 women who are twins evidently have duodenal ulcer and hyperthyroidism. The relapse and remissions of both diseases do not seem to travel in parallel lines, so that they cannot be accurately associated etiologically. The author's purpose in reporting these cases is to add to the reports of cases of identical diseases in identical twins and to show that duodenal ulcer should be considered quite common in the female sex and that duodenal ulcer occurs associated with hyperthyroidism.

Tendon Grafts.—According to Koch the flexor mechanism of fingers and thumb consists essentially of a powerful motor—the flexor muscles of forearm and palm, whose action is exerted on strong, perfectly smooth taut cords, the flexor tendons, which are held in firm, perfectly fitting sleeves, the fibrous tendon sheaths, and are attached to a series of hinged blocks of bone, the phalanges. The author is concerned chiefly with the cords and retaining sleeves. If the surface of the cord or the lining of the sleeve is roughened, movement is impaired. If the sleeve is slit open along its superficial aspect, tension on the cord lifts it out of the sleeve, and the mechanical advantage of the pull on the blocks of bone is lost. Such difficulties can be avoided by making incisions that avoid the superficial aspect of the retaining sleeve and so prevent the tendon from being lifted out of its sheath, by making certain that in any operative procedure bleeding is completely arrested and that no oozing persists to cause fibrous tissue formation between tendon and sheath, by using the finest and least irritating suture material in repair and by making certain that no infection is present. The most satisfactory method of securing return of function, if it has been lost, has been the removal of the scarred remains of tendon and adherent tendon sheath and substitution of normal uninjured tendon from some other part. The author shows in sketches the technic of substituting a free tendon graft for hopelessly injured flexor tendons and the results of substitution of tendon grafts from foot for divided and widely separated flexor tendons of the middle finger. He is reluctant to consider the use of foreign material such as amniotic membrane, cellophane or tantalum foil to prevent adhesions between tendons and surrounding tissues. In the few cases in which he observed the effect of such materials, the result has been quite the opposite from that which was anticipated.

Office Procedure for Hysterosalpingography. A. P. Hudgins.—p. 407.

Effect of Iodine Therapy During Pregnancy.—According to Zener and his associates some degree of thyroid enlargement during pregnancy has long been considered normal. An intake of iodine which is just adequate in nonpregnant females may become insufficient during gestation and so leads to thyroid hypertrophy. This "work hypertrophy" is evidenced by measurable changes in the basal metabolic rate and the blood iodine, both of which show a definite increase. The authors attempted to correlate these factors operating during pregnancy in treated and untreated patients. They found that the blood iodine level of normal nonpregnant adults in the Pacific Northwest was between 8 and 12 micrograms per hundred cubic centimeters. The average basal metabolic rate in pregnancy was found to be consistently higher than the averages reported from other areas. It remained elevated for at least six weeks following delivery. An elevation of the blood iodine level and the basal metabolic rate occurred during the first month of pregnancy. The blood iodine showed the greatest increase at the time of delivery, and both it and the basal metabolic rate remained elevated for at least six weeks after term. The administration of one tablet of lipoiodine (0.03 Gm. of available iodine) daily during pregnancy limited the usual increase in the basal metabolic rate and, conversely, increased the basal metabolic rate when below normal range. A reverse relationship between the blood iodine level and the basal metabolic rate was apparent. A change in the former was accompanied by a shift in the opposite direction of the latter. The average blood iodine level of infants at birth did not rise in parallel to the mother's. This suggests that the placenta interposes some barrier to the free passage of iodine from the mother.

Diverticulitis of the Colon in Gynecology.—Allen and Donaldson say that among 158,077 patients admitted to the Presbyterian Hospital in Chicago since 1934 there have been 362 who had diverticulitis of the colon, and 223 of these were females. The authors review observations on the 59 patients who were treated by the gynecologic staff of the hospital. Colon diverticulitis is a frequent cause of left lower quadrant pain, bladder irritation and pelvic mass formation. Diverticulitis should always be considered in the differential diagnosis in women with this clinical picture. This is especially true if the patient is over 35 years of age. It is urged that all such patients be more thoroughly investigated by x-ray and stool examination before surgery is undertaken. The palpatory pelvic findings of a tender, fixed, lava-like mass flowing out from the region of the sigmoid colon is often found and when present is very characteristic. So frequently do patients with colon diverticulitis have associated diseases that one must be careful in stating that the symptoms are due entirely to colon diverticulitis.

Normal Rh Positive Infants Born to Sensitized Rh Negative Women.—Hemolytic disease of the newborn due to Rh incompatibility between mother and fetus is usually preceded by serologic evidence of maternal sensitization. It has been observed, however, that an Rh negative mother who has not demonstrated laboratory evidence of Rh sensitization may give birth to a child who is afflicted with hemolytic disease of the newborn, and also that a normal child may be born to a woman who has shown Rh antibodies in her serum during pregnancy. As an illustration of the latter phenomenon, Howard and her associates report 4 cases in which clinically normal infants were born of mothers showing definite laboratory evidences of Rh sensitization. Among the many hypotheses presented in order to account for this phenomenon, the most logical explanation appears to be offered by the hypothesis of the anamnestic rise of nonspecific antibodies or the hypothesis of the protective effect of specific subgroup blocking antibodies.

*Carbon Tetrachloride Poisoning, with Report of Case. F. J. Geraghty and W. A. Rogers.—p. 242.

Carbon Tetrachloride Poisoning.—According to Geraghty and Rogers, carbon tetrachloride poisoning occurs either after ingestion of the chemical or after inhalation of the fumes. They report that a man aged 26 who developed a hepatorenal syndrome after having swallowed by mistake a mouthful of carbon tetrachloride immediately afterward drank milk and eggs and vomited. He then consumed three bottles of beer and several jiggers of whisky and felt well until the next day, when diarrhea with the passage of burning, watery stools ensued. Severe body pains and headache, vomiting and the voiding of dark colored urine followed. A picture characteristic of toxic nephrosis and hepatitis with renal shutdown and congestive heart failure developed. Rapid digitalization was employed. Ringer's lactate 1,000 cc. daily for four days was given by infusion for the acidosis. Vitamin K in daily doses of 20 mg. hypodermically was started. To combat anuria 50 cc. of 50 per cent dextrose was given every three to four hours for a total of ten injections and diathermy applied to both kidney regions for one-half hour twice daily. The patient's condition was critical between the seventh and the thirteenth day. On the fourteenth day there were signs of improvement in both renal and hepatic functions. The patient was discharged cured on the thirty-second day. The lethal dose of carbon tetrachloride in man is extremely variable. The maximum tolerated dose is 4 cc., but fatalities have occurred after ingestion of 1.5 cc. A case has been reported with recovery after ingestion of 30 to 40 cc. of the chemical. Alcohol and fat increase the toxicity of carbon tetrachloride, whether it is inhaled or ingested.

The Penicillin Produced by Aspergillus Parasiticus.—Arnstein and Cook described in 1944 the production of an antibiotic resembling penicillin which was provisionally termed "parasiticin." This was a metabolic product of Aspergillus parasiticus when grown under selected conditions, different conditions giving rise to other antibiotics. The authors report some properties of "parasticin," its production on a large scale and experiments leading to the final identification of the major constituent of the material as penicillin-II (penicillin-G or benzylpenicillin). The experiments show that the main antibiotic produced by A. parasiticus under the conditions described is penicillin-II, and the distinctive name "parasiticin" is no longer justified. The versatility of the Aspergilli in producing penicillins of different structures seems to be comparable with that of the Penicillia.

Longest Span of Life Based on Records of Centenarians in England and Wales. V. Korenchevsky.—p. 14.

Epidemiology of Pemphigus Neonatorum.—In November 1943 Allison and Hobbs were asked to investigate an outbreak of pemphigus neonatorum in 8 infants in the main nursery of the maternity unit of a Cardiff hospital. This was the beginning of a series of observations on the epidemiology of pemphigus neonatorum which continued for two years. During this period 2,719 infants were born in or admitted to the unit. Of this number 111 developed pemphigus neonatorum, 21 staphylococcic conjunctivitis and 4 both these conditions. The results of the serologic identification of the strain of Staphylococcus pyogenes isolated from the lesions of the 132 cases indicate that there were three outbreaks, each due to a distinct serologic type of the organism; there were also a small number of sporadic cases due to different serologic types of Staph. pyogenes. Investigations in one large nursery in which 93 of the cases occurred showed that the infecting strain was widespread in the infants' environment and was isolated from the noses of a high proportion of the nursing staff, from the noses of healthy infants, from blankets and gowns and from dust and air in the nursery. The evidence suggests that the main reservoir of infection was the nasal passages of the nursing staff and that the infants were infected in the nursery and not by their mothers. Members of the nursing staff who are aware that they are heavy nasal or skin carriers of Staph. pyogenes should observe preventive measures, such as the application of penicillin ointments to the nostrils two or three times daily and the sniffing in of these ointments. The author also considers the advisability of eventually discarding the large infant nursery in favor of the mother and infant being nursed together in a cubicle or in small wards.

Inhibitory Substance from Lactic Streptococci.—Mattick and Hirsch discuss an antibiotic substance, nisin, which was isolated from liquid cultures of Streptococcus lactis and is active in vitro against many types of pathogenic and other organisms. A method of semi-large scale preparation of the substance is described. Even in the impure state, nisin is effective in vivo against infections with Streptococcus pyogenes, Clostridium septicum and type II pneumococcus. Limitation of spread in experimental tuberculosis in guinea pigs has also been observed.

*Principles Underlying Management of Epileptic Patient. I. M. Allen. —p. 198.

Primary Tumor of Optic Nerve. W. J. Hope-Robertson.—p. 210.

Management of Epileptic Patient.—Allen defines principles for the management of epileptic patients, which he arrived at in the study of 3,500 cases. The epileptic factor and epilepsy are different things. The diagnosis of epilepsy depends on the presence of epileptic symptoms. The epileptic factor appears to be transmitted through family groups and appears to be subject to intensification and diminution as other familial factors. In the individual patient, the epileptic factor is characterized by waves of increased and of lowered intensity. The increase in intensity depends in part on the operation of other factors, which may thrust the epileptic tendency above the threshold of discharge. Emotional factors are most common. General toxic factors are responsible for the appearance of symptoms chiefly in childhood. Early physical changes in the brain and especially those which involve the cerebral cortex are present more often than is generally realized. Acquired changes affecting the brain may be degenerative changes in the cerebral cortex, vascular changes affecting the nutrition of the cerebral tissue, alterations in the balance of the cerebrospinal fluid, tissue changes due to trauma, and neoplastic changes. Epileptic attacks are not characteristic, but any fugitive, paroxysmal, disorderly, uncontrolled and recurrent manifestations of neurologic process at any physiologic level in the nervous system may be an expression of the epileptic state. All epileptic attacks are focal attacks. Every epileptic attack is a play between excitation and inhibition in the cerebral cortex, with a varying balance between them. Myoclonic jumps or jerks represent chiefly local excitation. Myoclonic jerks followed by weakness of the local part in which the jerks occur represent local excitation and then inhibition. The development of inhibition in response to excitation rising in one or in several portions of the cerebral cortex may lead to impairment of higher cortical functions. Proper management of the patient is possible only when the symptom has been recognized as an expression of the epileptic factor and every other factor which may thrust the tendency above the threshold of discharge has been identified.

Penicillin and Osteomyelitis of Superior Maxilla in Suckling Infants. J. Terracol, Y. Guerrier and J. Chalmeton.—p. 40.

Radium Therapy of Nasopharynx in Deafness.—Reynaud reviews papers by Crowe, Fowler, Proctor and others on the treatment and prevention of deafness by irradiation of the nasopharynx with radium or roentgen rays. The treatment is successful in all instances in which it is aimed at the prevention of deafness of tubal origin in children. The prognosis is less favorable in adults, but the treatment may be effective in preventing exacerbation of secondary lesions of the middle ear. Systematic employment of audiograms is indispensable for diagnosis and for control. The follow-up and occasionally continued treatment for the entire period of lymphoid hyperplasia and instability of the auditory function in young patients is essential. The usefulness of the nasopharyngoscope is emphasized. Irradiation of the nasal fossa should not be considered a panacea. The doses and the duration of the irradiation should be kept within cautious limits by consultation of the otologist with the radiotherapist.

*Hernia of Lung. C. Cacciari and G. Mazzecchi.—p. 263.

Hernia of Lung.—A man aged 67 received at the age of 6 years a trauma to the left half of the chest. At the age of 42 and again at 65 he suffered from cough which lasted about ten months. In the course of the last attack it was found that during inspiration or when the patient coughed a painless swelling protruded in the sixth intercostal space of the left half of the thorax. On palpation the contents of the swelling appeared to be pulmonary parenchyma. The amplitude of the pneumogram was diminished on the herniated side Hernia of the lung was demonstrated on roentgenologic examination as a clear, semioval image. The shadow was easily demonstrated in the left lateral position and following a diagnostic pneumothorax. The appearance and disappearance of hernia during inspiration and expiration, respectively, differentiates it from subcutaneous emphysema and from tumors of the thoracic wall.

*Diagnostic Value of Angiocardiograms Obstained by Direct Intracardiac Injection Through a Catheter. I. Chávez, N. Dorbecker and A. Celis —p. 121.

Diagnostic Value of Angiocardiograms.—A method is described for the injection of an opaque substance directly into the right chamber of the heart by means of a catheter introduced through the external jugular vein. The "right heart-tongue" circulation time can thus be determined. This time indicates the appropriate moment for taking x-ray films. With this technic the opaque medium cannot escape to venous regions; its mixing with the blood is thus minimized, and a sharp outline of the cardiac chambers is thus obtained. Images of the left chambers and of the aorta and its branches are especially good, something which has not been achieved by the usual methods. With the greater precision afforded by a sharper outline, the authors have confirmed some facts previously noted, such as the septal connections and the anomalous location of the arterial trunks. They were able to confirm or modify several of the current notions about the cardiac topography, both normal and pathologic. They found some new facts such as the difference between the systolic and the diastolic images of the right side of the heart and the fact that the left medial arc is usually formed by the left branch and not by the main trunk of the pulmonary artery. The location, morphology and size of the left ventricle, and the differences depending on systole or diastole have been determined. The present observations confirm Nylin's suggestion that a normal left ventricle empties completely during systole, whereas a dilated and failing ventricle retains "residual blood," as shown by residual opaque medium. The angiocardiographic image of some congenital malformations is described for the first time. In patent ductus arteriosus the pulmonary artery or its left branch is usually filled by rebound through the duct at the time the aorta, not the right ventricle, is filled. This fact was not observed constantly possibly because it requires exact timing of the pictures. The presence of this sign permits the conclusion that the duct exists; its absence does not rule out its existence. The authors have visualized clearly for the first time aortic coarctation. They have also obtained excellent filling of aneurysms; a clear distinction of these cases with those of tumors in the mediastinum can thus be established.

Topographic Radiologic Study of 200 Gastric and Duodenal Ulcers in Relation to Macroscopic Vascularization of the Stomach. G. de Busscher.—p. 491.

Carrot Soup for Intestinal Disturbances in Infants.—Peeters says that a carrot soup diet in nutritional disturbances of nurslings was used by Moro in 1907. The original recipe provided for 500 Gm. of carrots and 6 per cent sodium chloride in meat broth. Later the recipe was changed so that 500 Gm. of carrots was boiled for two hours in 1 liter of water, then passed through a fine sieve and filled up with boiled water to the total amount of 1 liter. To this 3 Gm. of salt was added. Young carrots are less suitable than mature ones. Carrot soup can be given to newborn infants and even to prematurely born infants. It is advisable particularly in dyspepsia and all forms of toxicosis. Carrot soup is usually given for from twenty-four to forty-eight hours, after which buttermilk, sour milk, protein milk or human milk is gradually introduced again. The effect of the carrot soup on the stool is usually noticeable after twenty-four hours. The diet promotes rehydration of the infant whose water economy has been impaired by diarrhea. As rehydration progresses, the toxic symptoms usually subside. The detoxifying effect of the carrot diet is probably partly due to the antiacidotic effect of its mineral salts. The carrot diet has an effect similar to the apple diet, banana diet, pectin-agar mixture and the like. These vegetable diets provide cellulose and pectins. The pectins are believed to be of greatest importance in diarrheal disturbances.

Etiology of Cirrhosis of Liver. A. H. Müller.—p. 192.

Therapeutic Application of Crystalline Estrogenic Substance.—Anselmino and Schildbach treated 202 women with menopausal symptoms or with menstrual irregularities by subcutaneous implantation of pellets or by injection of crystalline estrogenic substance. Artificial menopause in 119 of these patients was caused by hysterectomy. Bilateral oophorectomy or x-ray spaying had been performed in 16 of the 83 patients. Thirty-eight patients with uteri had secondary amenorrhea and 5 had oligomenorrhea. Relief of menopausal symptoms was obtained with a single implantation of 1 pellet of 25 mg. of cyren A (dioxydiethylstilbene) or of estradiol for a period of four to eighteen months. The effect of the cyren seemed to be stronger and more rapid but of shorter duration than that of estradiol because of the slower absorption of the latter. Removal of the pellet was required in about one third of the patients with uteri after two to four months because of the continuous bleeding from the proliferated endometrium. Treatment by pellet implantation is therefore suggested only for patients in whom the uterus has been removed surgically, while 2 ampules of 10 mg. of ovocylin (estradiol monobenzoate crystals) suspended in 2 cc. of a watery colloid liquid may be injected by the intragluteal route to patients with uteri. The four to eight weeks' duration of the effect of these injections was much shorter than that of the implantation of pellets, but the effect of the injections was not inferior to that of pellet implantation and was not associated with the risk of severe bleeding. The 43 patients with disturbances of menstruation were not benefited by implantation of pellets because of its irregular and incalculable effect. It is still too early for a definite evaluation of the effect of injections of a suspension of estrone crystals in patients of this type.

Liver Biopsy.—Falkenhausen and Gaida studied the role of the liver in disturbances of metabolism caused by albumin deficiency and hunger edema in 20 patients with inanition of several months' duration and with serum albumin contents of 3.6 to 5.88 Gm. per hundred cubic centimeters. There were no untoward reactions and no complications whether the liver puncture was performed before or after the paracentesis for ascites. Except for the reduced fat content, deposits of hemosiderin could not be demonstrated by Turnbull's blue, in contrast to the observations by other authors in animal experiments and on necropsy of patients who died from hunger edema. It is concluded that in man hemosiderosis may be associated with hunger edema which is no longer amenable to treatment. The occurrence of binuclear liver cells was demonstrated on liver biopsy. A more or less severe glycogen impoverishment was observed in the majority of the patients, although in some of them the glycogen content was almost normal but was irregularly distributed. There was no parallelism between reduced serum albumin and reduced glycogen, but apparently there was one between glycogen disappearance and duration of inanition. Death must result from the complete breakdown of glyconeogenesis. A therapeutic trial with intravenous administration of liver preparations is therefore suggested for patients with diabetes mellitus in hypoglycemic shock in which administration of grape sugar has been ineffective.

Pancreatic Necroses as Sequel of Generalized Arteritis. M. Aufdermaur. —p. 81.

Biliary Hepatic Cirrhosis: Clinical Evaluation of 17 Biliary Hepatic Cirrhoses Observed at the University Clinic in Zurich from 1936 to 1947 and Corroborated Post Mortem. Simone Troesch-Paillard.—p. 96.

Results of Examination and Symptomatology in Several Abdominal Disorders. F. Hirschberg.—p. 125.

Pancreatic Necrosis as Sequel of Generalized Arteritis. —Aufdermaur says that in cases in which pancreatic necrosis is due to an arterial disorder the destruction of the tissue is the result of a nutritional impairment of the glandular tissue. Ischemic necroses develop which are similar to infarcts in other organs, and as a rule a stenosing arteritis is the underlying cause. The author observed 10 cases of pancreatic necrosis which resulted from an inflammatory arterial disease that caused ischemia of the glandular tissue of the pancreas. The 10 case histories are reported. In all 10 cases foci of necrosis were observed, and near these foci there were severe arterial changes. In 3 instances the foci were so small that they were found only on microscopic examination. They always occurred in numbers and were yellow or showed hemorrhagic spots. The term "spotted pancreas" well characterizes the picture. In addition to the necroses, spotted atrophy of the glandular tissue is evident. Canalicular infection can be excluded in all cases; the glandular changes are always closely connected with diseased vessels. The arteritis of the pancreas is only a partial manifestation of a general vascular impairment. Results of vascular damage differ in the various organs. In the kidney arteritis usually produces the picture of malignant nephrosclerosis, whereas in the pancreas, myocardium and spleen ischemic tissue necroses are usually found. The renal changes usually predominate in the clinical manifestations. The clinical diagnosis is usually malignant nephrosclerosis or chronic nephritis. In several of the reported cases the coronary arteries, the adrenal capsular and cortical arterioles, the splenic and cerebral arteries and the aorta were involved in the inflammation. The cause of the obstructive arteritis may be a focal infection such as a chronic tonsillitis.

*New Contributions to Hereditary Transmission of Diabetes Mellitus. E. Hanhart.—p. 243.

*Action Mechanism of Ethyl Carbamate in Leukemias. S. Moeschlin. —p. 279.

High Voltage Current Accidents with Serious Muscle Damage.—Fischer and Rossier observed four serious high voltage accidents resulting from contact with high tension electric wires carrying a charge of 45,000 to 50,000 volts. The most noteworthy change was severe muscle damage accompanied with myoglobinemia and myoglobinuria, which in 2 cases led to death from anuria. High tension current accidents with severe muscle damage are accompanied with such severe tubular impairment of the kidney that death is probably chiefly the result of renal failure. Only high voltage current as a result of its extreme density is capable of producing such severe muscular damage over such extensive muscle regions in the course of about one second. In the presence of lower tension currents such effects are impossible because of the lacking density. The current of high voltage has the tendency to bypass internal organs (brain and heart) and to flow around the body like a mantle, involving chiefly muscle masses. The authors emphasize alkalization of the urine, immobilization of the injured extremities and bed rest for the patient in the prevention of renal damage. Sedatives should be given if the patient is excited. Plasma infusion is advisable regardless of whether plasma has been lost through burns or by diversion into the electrically impaired muscle. Subcutaneous infusion of isotonic salt or dextrose solution or perhaps rectal drop infusion is advisable to stimulate renal blood flow. In the presence of dark urine venesection and subsequent plasma infusion are advisable. Renal decapsulation may be necessary in prolonged anuria. Amputation of a severely damaged extremity may be necessary in order to prevent death from anuria.

Hereditary Transmission of Diabetes Mellitus.—On the basis of his observations Hanhart shows that a "manifestatio minima," i. e. an abnormal course of the blood sugar curves following administration of two doses of 25 or 50 Gm. dextrose (Staub's test), need not be present in the parents, in the siblings or in the children of diabetic patients. It is scarcely ever possible with this laboratory method to recognize premorbidity in a patient liable to develop diabetes. Five new genealogic tables, containing altogether 72 diabetic patients, prove that only simple recessive heredity can explain the prevalence of the disease in these families arising from an ascendancy which can be traced back to the sixteenth and seventeenth centuries. The appearance of diabetes observed on twelve occasions in one parent and one or two of the children can be explained without difficulty in every case as a pseudodominance according to Mendel's law. There are not less than 592 diabetic children originating from these families. The uncorrected disease coefficient for these is 2.02 per cent and thus about half as high as what Steiner computed on the basis of 411 diabetic children in Berlin (3.9 per cent). Hanhart made his observations in a Swiss mountain canton with about 35,000, mostly old established, inhabitants having relatively large families and considerable longevity. As regards eugenics the author concludes that patients with diabetes mellitus should limit their offspring and should never marry persons who have a family history of diabetes mellitus.

Action Mechanism of Ethyl Carbamate in Leukemias. —Moeschlin says that, stimulated by a British report, ethyl carbamate (urethane) was used in the treatment of leukemia in Löffler's clinic. He relates some investigations that were undertaken to study the action mechanism of this substance in leukemic conditions. The blood picture of healthy men who were treated with therapeutic doses of ethyl carbamate was characterized by a distinct decrease in the number of lymphocytes, while the granulocytes, thrombocytes, erythrocytes and reticulocytes were not noticeably affected. Even the slight depressant action on mitosis in granulocytopoiesis observed in

2 cases was still within the region of experimental error. In rabbits no change in the blood picture could be determined with daily doses of 1 Gm. even after prolonging treatment for ninety-two days. In chronic myelocytic leukemia the myelogram and the splenogram showed no appreciable changes in cell composition apart from a distinct increase in erythroblasts and polymorphonuclears. The persistence in the bone marrow and spleen of the leukemic cell picture when ethyl carbamate is administered is striking when compared with the changes occurring during arsenic and x-ray therapy, where there is a pronounced shift toward ripe cells. The calculation of the mitotic index for the leukemically deranged white (granulocytopoietic) groups under the influence of ethyl carbamate shows a decrease in mitotic activity to one half of the former value, while the mitotic index for erythropoiesis rises to double. The favorable action of ethyl carbamate in chronic leukemic disease is therefore a consequence of the strong selective suppression of the cell division of the pathologically deranged "neoplastic" leukemic cell groups. These findings suggest search for similar substances with a therapeutic effect on mitotic activity of malignant tumors.

*Liver in Amebiasis: Clinical Aspects. J. Tanca Marengo.—p. 79.

Amebic Hepatitis.—Tanca Marengo reports good results with intravenous emetine therapy in acute or chronic amebic hepatitis of adults. The diagnosis is made on the presence of hepatomegaly and the therapeutic response to emetine. Treatment consists in daily intravenous injections of 4 mg. of emetine and 60 mg. of thiamine for eight or ten days, followed by the same doses intramuscularly for one week. The treatment is contraindicated when symptoms of intolerance (tachycardia and asthenia) appear. When the emetine therapy for diagnosis is not conclusive, an exploratory laparotomy is indicated for the local treatment of the lesion.

*Bilateral Calcification of Ovary Due to Tuberculosis: Rare Case. C. Scartozzi.—p. 209.

Calcification of Ovary.—The subject of this report is a nulliparous woman aged 55 who for the last seven years had observed enlargement of the abdomen and had recently had lumbosacral pain. X-rays revealed calcified ovaries. Bilateral oophorectomy disclosed calcification of the ovaries whereas the remaining genitalia were normal. Microscopic study of the ovaries led to a diagnosis of caseous tuberculosis with advanced calcification. The isolated localization of the tuberculous process suggests hematogenic origin of infection.

*Plasma Fractions in Hemophilia. S. van Creveld and G. G. A. Mastenbroek.—p. 1305.
Studies on Urines of Parturient Women. G. A. Lindeboom.—p. 1313.

Unusual Case of Open Ductus Botalli.—Keizer reports that a girl aged 13 who had been under his observation for about a year was 6 inches under normal size and much reduced in weight. There were indications of an open ductus botalli, and a ligation was considered. The thorax was opened, but the conditions found were such that effective surgical treatment was impossible. The thorax was closed and the child died two weeks later. At operation and at necropsy it was found that the aorta supplied the blood for the head only, whereas the open ductus botalli formed a passage between the pulmonary artery and a pseudoaorta. There was also a large defect in the ventricular septum. A diagram illustrates the peculiar congenital malformation of the heart.

Plasma Fractions in Hemophilia.—Van Creveld and Mastenbroek report the results obtained in hemophilic conditions, in vitro as well as in vivo, with a fibrinogen solution that was obtained by ether precipitation from normal plasma. By the injection of this solution of fibrinogen it was possible to reduce the coagulation time in hemophilic patients to a great extent and for a long period. Repeated intravenous injections of this substance produced no disagreeable reaction and was not followed by a refractory period. It is still an open question whether this substance is a protein or a substance that is bound to protein. Products that promote coagulation of hemophilic blood in vitro were obtained also from the placenta, but these substances were ineffective in vivo.

Fulminant Form of Meningicoccic Sepsis (Waterhouse-Friderichsen Syndrome): Epidemic on Board Ship. P. H. Kramer.—p. 1470.

Epidemic of Comedones and Vitamin A Deficiency.—Hohmann and Beening report 13 cases observed at the dermatologic clinic of the University of Groningen in which there were large numbers of comedones frequently associated with perlèche, phrynoderma, xerosis and in 1 case xerophthalmia. No cosmetics were used. The authors think that the low content of vitamin A in the blood serum and the favorable effect of vitamin A application refute Garnier's opinion that the disorder is due to the use of harmful cosmetics. Garnier and other French dermatologists had observed such "epidemics of comedones" during the war. Hohmann and Beening say that as early as 1909 Dore of England described a disorder which is characterized by a large number of blackheads.

Uterine Fibromyoma in Extrusion (Fibromyoma Uteri in Expulsione).—Madsen discusses uterine fibromyomas which are extruded by uterine contractions in a mechanism like that of childbirth in connection with 60 cases (44 submucous, 16 intramural), of which 54 developed from the uterine cavity and 6 from the cervical canal. Microscopic examination was made in 55. One case was fatal. These tumors, he says, appear in about 6 of 100 cases of fibromyomas, vary from the size of dove's egg to that of a child's head, the submucous ones rarely being larger than a hen's egg, and most often occur between the ages of 40 and the menopause and seldom after the menopause. Certain diagnosis is made only on gynecologic examination; a dilated external os containing a tumor with a peduncle or broadly attached to the wall of the uterine cavity is characteristic. The symptomatology is variable, all transitions being seen from cases without symptoms to those with fever, toxemia and purulent discharge in the gangrenous forms. The strong uterine contractions during menorrhagia and metrorrhagia combined with necrotic changes lead to loosening of the tumors from the uterine walls and their expulsion. Treatment must be individualized. The prognosis is good. Spontaneous recovery may occur, but there is danger of anemia in untreated cases.

Poliomyelitis in Mother and Newborn Infant in Family with Multiple Cases.—Frøvig says that of the 4 members of a family having poliomyelitis during the same epidemic 2 were a mother aged 20 and her newborn child. The mother apparently acquired the disease during the last days of pregnancy; the lower extremities became paralyzed on the second day after delivery. She can now walk with the aid of supporting bandages and canes. The infant developed symptoms of poliomyelitis on the fourth day of life and four days later could not move arms, legs or head. On discharge there was still considerable paralysis, especially in the extremities on one side. Poliomyelitis in infants has not before been reported earlier than five days after birth (Wernstedt). If the child was infected after birth, the incubation period in poliomyelitis can be as short as four days. The possibility of intrauterine infection is considered, but evidence of it is lacking. Thirty-seven years ago the mother's uncle had poliomyelitis.

Penicillin Therapy in Early Syphilis. C. Huriez and M. Desurmont—p. 401.

*Treatment of Carriers of Diphtheria Bacilli with Tyrothricin. R. Turpin, J. Combet, J. Roujeau and R. Seillon.—p. 402.

Penicillin Therapy in Early Syphilis.—Twenty-two patients who had early syphilis were treated by Huriez and Desurmont with penicillin and 179 patients were treated with penicillin combined with arsenicals or bismuth or with penicillin combined with both of these drugs. Healing of syphilitic lesions occurred in 50 per cent and the serum became negative in one third of the patients treated with penicillin alone in spite of the total dose of 4,800,000 to 9,600,000 units. Serologic failures were reduced from 72 to 51 per cent when treatment with arsenical preparations was combined with penicillin; they were reduced to 41 per cent by combining penicillin with bismuth, and to 37 per cent by treatment with penicillin, arsenic and bismuth combined. Healing of syphilitic lesions took place in 85 per cent of the patients treated with bismuth as compared with 45 per cent treated with penicillin. Arsenic proved best since cicatrization occurred in 90 to 100 per cent of the patients treated with arsenical preparations and penicillin combined, with or without bismuth. The authors recommend a regimen of 2,400.000 units of penicillin and twelve injections of bismuth *within one month,* to be repeated twice after two weeks of rest, or triple successive treatment according to Wile, starting with an injection of an arsenoxide for the first three days, followed by a course of 1,200,000 units of penicillin during the next week and terminated by five injections of bismuth. These treatments should be supplemented with courses of bismuth.

Tyrothricin in Diphtheria Carriers.—Turpin and his co-workers dusted the nasopharynx of 32 carriers of diphtheria bacilli (infants, children and adults) with a powder of bismuth subnitrate and tyrothricin. The powder was applied three times within twenty-four hours one hour after the meals and was repeated three times in seventy-two hours. In 4 of 28 carriers the diphtheria bacilli disappeared after one dusting with a powder of 0.5 Gm. per hundred cubic centimeters, in 16 after two dustings with this powder and in 8 after nine dustings. The total amount of tyrothricin contained in these nine dustings was 0.0045 Gm. The follow-up of these former carriers three times a week and then at intervals of two weeks for more than two months did not reveal any recurrences. The 4 resistant carriers were given a second course of nine dustings but with a powder of 5 Gm. per hundred cubic centimeters and with a total amount of 0.045 Gm. of tyrothricin. The density of the diphtheria bacilli was reduced in 2 of these carriers and the bacilli disappeared in 1 after twenty-one dustings with powder of 5 Gm. per hundred cubic centimeters. The dustings were well tolerated, and there were no untoward reactions even in the infants. The three partial failures are not to be considered as definite failures. This method of treatment is recommended for reducing the incidence as well as the hospital stay and the period of inactivity of carriers of diphtheria bacilli.

Revue de la Tuberculose, Paris

*Secondary Pulmonary Infiltration Originating from Lymph Nodes. A. Dufourt and P. Mounier-Kuhn.—p. 155.

*Tuberculosis in Denmark: Etiologic Considerations. T. Madsen.—p. 170.

Secondary Pulmonary Infiltration.—Dufourt and Mounier-Kuhn report 15 cases of secondary pulmonary infiltration from perforating lymph nodes in children and adults between the ages of 2 and 25 years. Forty roentgenograms and tomograms were made. Bronchoscopy revealed that the incidence of tracheobronchial lymph nodes perforating and fistulizing into the bronchi three to six months or even ten to twelve months after the primary infection is much higher in children and in adults than was expected. The clinical aspect of this minor syndrome may be less pronounced and more polymorphous than that of the severe syndrome causing dyspnea and disseminated bronchopneumonia. There may be small fistulas frequently masked by edema or secretion with more or less dense shadows punctuated with miliary granules or nodules the size of a pea. Fistulas with limited shadows have a tendency to spontaneous recovery; those with considerable densities may have a less favorable prognosis and artificial pneumothorax is suggested for their treatment. Considerable adenopathy may produce only small fistulas, but perforating lymph nodes of small volume may cause complications such as stenosis or atelectasis. Tomograms which show the hilus and which demonstrate a bronchus with thickened walls originating from a hypertrophic hilar lymph node and reaching the center of the infiltrated lung area may be an aid in the differential diagnosis against precocious tertiary infiltration in adults.

Tuberculosis in Denmark.—Statistics presented by Madsen show that, except for a temporary increase caused by alimentary deficiency during the first world war, the mortality rate of tuberculosis in Denmark had declined constantly since the end of the last century up to 1939. The low mortality rate of 3.5 for 10,000 inhabitants was maintained during the period of 1939 to 1945. The mortality rate in the capital was somewhat higher (4.4) as compared to that in the provincial towns (3.6), but the mortality rate in the villages was still lower (2.7 for 10,000 inhabitants). In addition to the fact that tuberculosis is a reportable disease in Denmark, treatment and isolation of tuberculous patients in sanatoriums (1 bed for every thousand inhabitants) and community dispensaries (1 for every hundred thousand to 200,000 inhabitants) are responsible for a considerable increase in the number of persons with a negative tuberculin reaction. In Copenhagen the percentage of school children with a positive tuberculin reaction has been reduced from 16.6 in 1937 to 5.6 in 1945. Seventy-five per cent of the inhabitants of Copenhagen between the ages of 15 and 34 years submitted voluntarily to an examination. Prophylactic inoculation with BCG vaccine was done on a large scale among those with a negative tuberculin reaction. Similar measures are intended for the population older than 35. BCG vaccination is obligatory for members of the armed forces.

*"Quinine Test" for Function of Liver. L. F. Pallardo.—p. 721.

Peptic Ulcer. J. M. Mesa.—p. 742.

"Quinine Test" for Function of Liver.—Pallardo carried out the quinine test for liver function in five groups of persons: (1) 55 patients with hepatic or biliary diseases, (2) normal persons, (3) patients with various diseases and a normal liver, (4) alcoholic addicts and (5) constitutional asthenics. The results were positive in all patients but 2 with hepatic disease and in half the patients with biliary diseases. The test proved to be of greater diagnostic value than the Takata and Weltmann tests, formolgelification in the blood serum and in the blood plasma, and the velocity of sedimentation of erythrocytes. In normal persons and in acloholic addicts the quinine test was more reliable than the other tests, with negative results in 41 out of 42 normal persons and positive results in 4 out of 10 alcoholic addicts (the positivity showing latent liver deficiency). There were also positive results in 5 out of 14 cases of constitutional asthenia. In 3 of the 5 cases the galactosuria test also was positive. Positive results in this group show functional insufficiency of the liver in constitutional asthenia.

Book Notices

Physical Medicine in General Practice. Edited by Arthur L. Watkins, M.D., and others. The American Practitioner Series. Reprinted from Clinics, April, 1946; Vol. IV, No. 6. Fabrikoid. Price, $5. Pp. 341, with 7 illustrations. J. B. Lippincott Co., 227 S. Sixth St., Philadelphia 5, 1946.

The place of physical medicine in the fields of medicine and surgery and in those specialties in which it is of particular value is presented by a group of contributors each one of whom has been carefully selected for his experience and long years of study of the subject. The content of the book is well balanced. Emphasis is placed on the diagnostic and therapeutic aspects of physical medicine according to their importance in each field. The book is written primarily for practicing physicians and surgeons. Therefore the technical side of physical medicine has been minimized and the emphasis has been placed on the clinical application of the various technics to the conditions commonly encountered by the practitioner. The excellent chapter on factors to be considered in prescribing physical medicine by Dr. Earl C. Elkins is of particular significance, for it is only through the use of a carefully considered and clear prescription that the practitioner can adequately instruct the physical therapist or occupational therapist and so obtain the maximum benefit for his patient. Emphasis is given also to the importance of the complete rehabilitation of the patient to the point where he may resume a normal life or a life in which his maximum capacity is realized. There has been great need of an interpretation of the rapidly developing field of physical medicine to other practitioners. This volume, which has been developed under the editorship of Dr Arthur L. Watkins, ably presents the contribution of physical medicine to the care of many types of patients and should be of interest and value to many members of the medical profession

Pellagra in the Oto-Neurology and Rhino-Laryngology. By Otto L. E. de Raadt, M.D. Boards. Pp. 172, with 4 illustrations. Universitaire Pers Leiden, Nieuwsteeg 1, Leiden, 1947.

The author has examined 160 cases of pellagra in the prison camps of Bandoeng, Batavia and Pakan Baroe from 1942 to 1945. It is admirable that he was able under the most adverse conditions to carry out such a splendid clinical observation. In his monograph with 131 bibliographic references he gives a description of pellagra from the pathologic and anatomic points of view and stresses the point that changes of the skin are by no means present in all cases and that the labyrinthine symptoms are initial signs occurring long before a dermatitis may appear. He further emphasizes the otoneurologic syndrome which consists of labyrinthine hyperexcitability, dizziness, disturbances of the balance and nystagmus, together with such concomitant symptoms known to be present in pellagra. It is interesting that cochlear symptoms have been observed in only a small number of cases (26 per cent), consisting of tinnitus and conduction deafness. The author supposes that the labyrinthine symptoms are caused by an involvement of the brain stem due to avitaminosis, whereas the internal ear is not involved. Necropsy material was not available, but de Raadt states that "the underlying pathology of the otoneurological disturbances is a degenerative brain stem encephalitis." He further believes that in temperate climates patients evidencing Ménière's syndrome may have early and sometimes monosymptomatic pellagra. He feels that a riboflavin deficiency plays the most important part in bringing out the central nervous system symptoms, the retrobulbar neuritis and some associated symptoms. In therapy he feels one should play safe and certainly do no harm by giving all factors of the B complex, and occasionally the addition of desiccated hog stomach should be considered.

Psychopathology: A Survey of Modern Approaches. By J. Ernest Nicole, O.B.E., L.M.S.S.A., D.P.M.R.C.P.&S., Medical Superintendent, Winwick Mental Hospital, Warrington, England. Fourth edition. Cloth. Price, $4.75. Pp. 268. William Wood & Co., Mt. Royal & Guilford Aves., Baltimore 2, 1946.

In the preface to the first edition the author wrote "This handbook . . . is designed to provide a general survey of the different schools of today . . . : to show some of the points at which different lines of approach approximate to one another: and to indicate, by references to important authors, directions in which further reading might prove profitable and interesting." He has succeeded exceedingly well. He outlines the different approaches to psychopathology from Maxwell, Mesmer, Charcot, Babinski and Janet to Freud and his followers, who constitute the backbone of dynamic psychiatry as practiced today. In so doing he outlines the views of many others who have contributed something of value to the understanding of psychopathology. The theories, formulations, elaborations and contributions of such students as Jung, Adler, Prince, Watson, Frost, Burredge, Kretschmer, Marston, McDougall and Horney are clearly outlined. For the most part the author cleverly abstracts the formulations of the different schools of thought without passing judgment on their contributions. Probably the only real weakness in the book is the fact that there are a few exceptions to this pattern. Some readers may criticize Nicole's attempts to classify people into character types. Such attempts have been made by many writers, and the value of such classification is of doubtful value. The bibliography is excellent and the index adequate. Students of psychopathology will not only profit from reading this book but may be stimulated, as the author suggests, to further investigation of this important subject.

Schorzenia narzadów krwiotwórczych w świetle badań bioptycznych szpiku kostnego, śledziony i gruczołów chłonnych. [By] Dr. Julian Aleksandrowicz. [Diseases of Hemopoietic Organs in Light of Biopsy Studies of Bone Marrow, Spleen and Lymph Glands.] Boards. Pp. 265, with 57 illustrations. D. E. Friedlein, Rynek Podgórski 2, Cracow, 1946.

This monograph deals with diseases of hemopoietic tissues based exclusively on the study of biopsy material obtained by sternal, splenic and lymph node puncture. Several books of the same sort have been published recently in various languages. Technic of biopsy and of preparation of slides, anatomy and physiology of blood forming tissues (a very good chapter), relation between the nervous system and bone marrow, and nomenclature are treated in five general chapters. The remaining 150 pages are taken up with systematic discussion of various diseases arranged in the usual manner.

The presentation is clear and thorough. The author, a distinguished hematologic investigator, displays a profound knowledge of literature of various countries. His critical analysis of the many controversial questions makes the book especially valuable to the advanced student. The illustrations are not of the same order of excellence as the text. Many show glaring imperfections.

The book is a credit to the tenacity and scientific enthusiasm of its author. As stated in the introduction, the first manuscript was lost when Cracow was occupied by the Germans at the beginning of the war. Fortunately the slides were saved. The text was rewritten between 1942 and 1944. The manuscript had to be buried in the ground in May 1946 and was dug out in February 1947.

Fundamentals of Clinical Neurology. By H. Houston Merritt, M.D., Professor of Clinical Neurology, College of Physicians and Surgeons, Columbia University, New York City, Fred A. Mettler, M.D., Ph.D., Associate Professor of Anatomy, College of Physicians and Surgeons, Columbia University, and Tracy Jackson Putnam, M.D., Professor of Neurology and Neurological Surgery, College of Physicians and Surgeons, Columbia University. Fabrikoid. Price, $6. Pp. 289, with 96 illustrations. Blakiston Co., 1012 Walnut St., Philadelphia 5, 1947.

This book has been designed for the student who is just beginning the study of clinical neurology, and it is admirably suited to his needs. There is a definite correlation of anatomy and physiology with the clinical manifestations of disease. The structure and function of the nervous system are presented in detail and with excellent illustrations. These fundamental subjects are presented much more fully than are the clinical aspects of neurology, but they should be in a book of this character. This presentation provides the medical student late in his sophomore or early junior year with a much needed review of his past work and with just enough clinical material to bring out the correlation with the basic sciences to whet his appetite but not to overwhelm him. The technic of examining the patient for the purpose of eliciting the manifestations of neurologic disease is also discussed.

On page 13 the statement that "If the patient does not complain of difficulty in vision . . . examination of acuity and visual fields need not be routine" is poor advice which, if followed, will eventually lead to error. The statement on page 70 "Immediately after nerve section, hyperalgesia is present for several hours in the denervated area" is not true if the author means hypersensitivity to painful peripheral stimuli, which is the usual meaning of hyperalgesia. In the table on page 83 in which various intoxications of the nervous system are presented the toxic effect of lead on the cerebrum is omitted. There are a few similar minor errors.

The book is to be highly recommended to the beginning student in neurology. It is not a complete textbook in this field and was not intended to be. There is a useful index but no references to the literature.

An Approach to Social Medicine. By John D. Kershaw, M.D., D.P.H., Medical Officer of Health, Accrington, England. Cloth. Price, $4.50. Pp. 329. William Wood & Co., Mt. Royal & Guilford Aves., Baltimore 2, 1946.

The book is written for members of the medical profession and for interested laymen. The bibliography indicates that the author has read widely in the popular, mystical and philosophical literature of our times but not too much in the fields of economics, political science, sociology and logic. He notes that in the past the position of medicine was defensive, since it had to be content with the work of conquering diseases. Now that medicine has found methods to cure or control many diseases it is able to consider taking the offensive in a twofold activity: (1) "development of medicine in relation to social life" and (2) "the influencing of social activities in the interests of human well-being."

In the first part of the book the author defines society as the association of human beings for common defense against the hazards of life and for the exploitation of natural resources in the interest of human well-being. Then he develops his conception of the structure and function of society. It is unfortunate that he considered society as a living organism when he is aware that the analogy is inadequate for his purposes. He suddenly drops the comparison when he comes to the chapter devoted to the collective mind. Social theory based on biologic analogy is groundless.

Dr. Kershaw's real contribution is in part II, where he shows that the task of social medicine lies in the integration of medicine with social activities. He is on factual ground when he reviews [illegible] contributions of medicine to social progress through the [illegible]vement of the functioning powers of the members of [illegible]y. Health is redefined to be not merely freedom from [illegible]ase but a state of fullest functional efficiency. Medicine at present is driving toward a fuller understanding of the relation of environment to health and disease. More than that, it is making serious efforts to modify the factors which underlie the social problems of health. In England doctors have trespassed, particularly during the war, the boundaries of traditional medicine in their activities concerned with malnutrition. Kershaw discusses the more important of these problems and offers suggestions for practical action in the difficult task which social medicine faces, albeit advising the reader to take them for just that and no more.

Studies and Essays in the History of Science and Learning Offered in Homage to George Sarton on the Occasion of His Sixtieth Birthday, 31 August 1944. Edited by M. F. Ashley Montagu. Cloth. Price, $12. Pp. 597, with illustrations. Henry Schuman, 20 E. 70th St., New York 21, [n. d.].

This book is interesting and informative, as might be anticipated from the brilliant list of contributors to this volume that honors George Sarton. However, any random selection of essays under circumstances such as these can hardly be integrated or subjected to rigid selection. The contributions vary in quality from those of genuine value to the trivial. The editor is to be complimented for the skilful balance that he has achieved. Among the interesting papers are those of Charles Singer (The Philosophical Background of Vesalius), Harcourt Brown (Buffon), Cassirer (Galileo's Platonism), Lenzen (Helmholtz) and Delevsky (The Idea of the Eternal Cycle). Apart from the papers on Vesalius and Helmholtz, few of the contributions will be of particular interest to physicians. The book is well printed, but no index has been supplied.

Office Immunology Including Allergy: A Guide for the Practitioner. Edited by Marion B. Sulzberger and Rudolf L. Baer. Authors: Marion B. Sulzberger, M.D., Professor of Clinical Dermatology and Syphilology and Director, New York Skin and Cancer Unit, New York Post-Graduate Medical School and Hospital, New York, and others. Cloth. Price, $6.50. Pp. 420, with 16 illustrations. Year Book Publishers, Inc., 304 S. Dearborn St., Chicago 4, 1947.

This excellent book is a compilation by six authors under the editorial supervision of M. B. Sulzberger and R. L. Baer, both dermatologists. The other authors include an allergist (W. C. Spain), a pediatrician (Abram Kanof), an immunologist (A. J. Weil) and a third dermatologist (N. M. Kanof). The material presented is a compilation of practical information. This is at times rather loosely put together under general headings, so that apparently unrelated conditions like diphtheria, botulism and brucellosis are included in the same chapter. The subject index is adequate. No bibliography is included.

As one might expect in a compilation by six authors, the quality of the material presented varies. The first two chapters, on common technics, are well written. Difficult procedures are carefully described and detailed precautions given when any danger might exist from their improper use. The chapter dealing with transfusion reactions is excellent. The difficult subject of the Rh factor is clearly and simply explained. The subject of dermatologic allergy is likewise well covered by Sulzberger and Baer. Here much useful information on drug allergy and contact dermatitis has been included from many sources. Throughout the book the authors indicate where materials for special tests or treatment can be obtained and the dose to be used.

The deficiencies of the book are primarily in the attempt to cover too many subjects in too little space. It would have been much better to omit the chapter on miscellaneous allergies. This consists of nine pages devoted to allergy of the eye, the gastrointestinal tract, allergic headache and "other pathologic states attributed to allergy." It is impossible to do justice to such a variety of subjects in so little space. Similarly the chapter on immunology of infections could be greatly improved by a more detailed discussion of common conditions. The uncommon or rare diseases which have been included merely because one of their characteristics is an altered acquired specific tissue reactivity might have been omitted to provide more space for common diseases.

The Medical Story of Early Texas, 1528-1853. By Pat Ireland Nixon, M.D., President, Texas State Historical Association, San Antonio, Texas. Foreword by Dr. Chauncey D. Leake. Cloth. Price, $6. Pp. 507, with illustrations. Published by the Mollie Bennett Lupe Memorial Fund. The Author, 1022 Medical Arts Bldg., San Antonio 5, Texas, 1946.

For some reason that is not clear, most of the state medical histories which have appeared in recent decades have related to the Southern states—to Virginia, Kentucky, Tennessee—and one might even place California partially in that category. The North Carolina Medical Society is seriously at work on a history of that state. Now, in presenting this study on Texas, Dr. Nixon has given us the story of a state whose unusual experience under several flags lends color to its medical as well as its political history. Dr. Nixon bases the account on a thorough use of a wide range of published and unpublished sources, and in this respect his work is a model for future state histories.

The greater part of the book is distinctly readable, both as a matter of style and because of the quotations from often dramatic original documents. The story opens with the Indians and with vivid and almost incredible medical adventures of Cabeza de Vaca during the sixteenth century and then proceeds through the Spanish, French and Mexican periods to the era of the republic. Although the political background of Texan experience was quite different from that of other states, the medical panorama unfolded here was usually similar to that of the United States. There was the same tragic struggle with endemic and epidemic fevers against the odds imposed by scientific ignorance. There were the same early and ineffectual attempts to provide hospitals, regulate medical practice and set up medical schools and societies. Hordes of quacks and sectarians descended, as elsewhere, on the Lone Star State. Not until the 1850's, after Texas was admitted to the Union, was the state medical society finally established.

In certain of the chapters the author gives a series of biographic sketches of physicians. While these are often interesting in themselves and have reference value, they tend to slow the reader down. He loses sight of the forest for the trees. Finally, however, one emerges where one can see the picture whole in certain concluding chapters on education, quackery, ethics and organized medicine. The study will not only appeal to Texans but will aid in rounding out knowledge of our national medical history.

Color Atlas of Hematology with Brief Clinical Descriptions of Various Diseases. By Roy R. Kracke, M.D., Dean and Professor of Clinical Medicine, Medical College of Alabama, Birmingham Alabama. For Medical Students, Laboratory Technicians and General Practitioners of Medicine, with Clinical and Hematologic Descriptions of Blood Diseases, Including a Section on Terminology, a Section on Technic and a Summary of Blood Findings in Various Diseases. Fabrikoid. Price, $5. Pp. 201, with 35 plates. J. B. Lippincott Co., 227 S. Sixth St., Philadelphia 5, 1947.

This little offspring of Dr. Kracke's well known textbook on Diseases of the Blood is designed for use by medical students, laboratory technicians and general practitioners. It starts with a chapter on the definition of hematologic terms which should be valuable to the beginner. The origin and the morphology of the blood cells are discussed in detail. Well reproduced colored plates should help in the sometimes difficult task of identifying and classifying the various normal and pathologic cell types. Chapters on the evaluation of pathologic findings such as leukocytosis, lymphocytosis, monocytosis, eosinophilia, the various types of anemia and the leukemias follow, all accompanied with characteristic color plates. The composition of the bone marrow in health and disease is discussed. A chapter with pictures of the blood parasites and of the hematologic findings in various laboratory animals can also be found in this little book. After a brief description of the hematologic technics used in the author's laboratory, a summary of the hematologic findings in various diseases and conditions forms the last chapter of this manual. The book will prove its usefulness to the professional persons for whom it is designed. However, the text of the expected second edition should be brought more up to date. For instance, vitamin K, a naphthoquinone derivative, can hardly be defined as the precursor of prothrombin which is a protein; the life span of the erythrocyte is not thirty days but a hundred to a hundred and twenty days, as shown by many recent investigations; plate 33 shows the blood picture of the white rat and the legend reads "no platelets shown since they are scarce"; on the following page the platelets of the rat are listed as numbering 600,000 to 700,000 per cubic millimeter.

La digitale et les strophantines: Pharmacodynamie-thérapeutique. Par D. Danielopolu, professeur de clinique médicale à la Faculté de médecine de Bucarest. Paper. Pp. 206, with 56 illustrations. Masson & Cie, 120 Boulevard Saint-Germain, Paris 6e; Imprimeriile "Independenta," Bucharest, 1946.

This monograph contains a review of the literature together with the author's own work in the field which dates back to the early nineteen hundreds. A consideration of the physiology of the autonomic nervous system in normal and pathologic states is followed by a discussion of the histology and the physiologic properties of the heart and blood vessels, and of their innervation. Then follows a comprehensive review of the literature dealing with the pharmacology of digitalis.

The author's concept regarding the mechanism of the action of digitalis and strophanthus preparations can be summed up as follows: The fact that digitalis drugs act in a manner similar to potassium and acetylcholine on certain properties of the heart and in a manner similar to calcium and epinephrine on others led him to the view that these drugs act to a large extent, but not exclusively, by cholinergic and adrenergic actions, the manner of action depending on whether the drug is acting on the adult (myocardium) or the embryonic (conducting system) tissue of the heart. The usual substances operating adrenergically and cholinergically on the heart influence these two types of tissue in the same manner. Digitalis, however, acts one way on tonicity, excitability and contractility and in a contrary fashion on automaticity and conductivity of the heart. The difference in digitalis action is assumed to be due to a difference in reactivity of embryonic and adult cardiac tissue to the drug. The author also believes that digitalis drugs act in a nonspecific manner via this cholinergic and adrenergic stimulation; this action is reversible. In addition, these drugs have a specific or toxic action which is peculiar for these drugs and is irreversible. The results of animal experiments, as well as those on man, which the author performed, are used to confirm this hypothesis. This theory of the author on digitalis action may appear strange to many readers and requires supportive evidence before it can be accepted.

The last chapter is devoted to a method of resuscitating the heart which he has found effective clinically and in animal experimentation. When cardiac standstill ensues he uses intracardiac injection of a mixture of epinephrine, atropine and strophanthus and at the same time performs massage of the heart through the abdomen and thorax as well as maintaining artificial respiration.

This book should be of value to the investigator as well as to the cardiologist and the internist. The review of the classical literature is excellent, the bibliography is extensive and the author's hypotheses are at least provocative.

Urology in General Practice. By Nelse F. Ockerblad, B.S., M.D., F.A.C.S., Professor of Clinical Urology, University of Kansas School of Medicine, Kansas City, Kansas. Second edition. Cloth. Price, $5.75. Pp. 392, with 98 illustrations. Year Book Publishers, Inc., 304 S. Dearborn St., Chicago 4, 1947.

This practical and readable book, as Dr. Ockerblad says in the preface to the first edition, "is the product of many years of endeavor to teach the specialty of urology to medical students and to interpret it to the profession in general." There are few references to the literature and no bibliography. A book of this size and with the purpose the author had in view would lose a great deal of value and space would be wasted, if controversial matters were treated at length. The danger in this method of presentation lies in the necessary dogmatism of the author, and the inability of others less skilled and intuitive to get equally good results from his methods.

Chapter II covers instrumentation of the urethra and is written with great common sense and from a large experience. Chapter III differentiates between pyelitis and pyelonephritis in a manner not in accord with most modern opinion. The chapter on nephritis and nephrosis is sketchy and vague, and it is questionable whether it should have been included in a book of this type. Many of the therapeutic measures advocated are outmoded and highly questionable. A quotation from the section on the treatment of anuria in which the use of intravenous fluids is discussed says that "when there is complete anuria 5,000-7,000 cc. of fluids may be given (daily) to increase the hydrostatic pressure to the point where the kidneys must secrete (but this must not be continued too long)." Unfortunately there is no point of pressure at which kidneys "must" secrete, and present opinion is to the effect that in anuria only sufficient fluid should be given to replace the fluids lost in perspiration, through the bowel and in respiration; 1,500 cc. in twenty-four hours is sufficient to take care of this loss. More fluid than this will only increase edema of the interstitial tissues of the kidney and may cause cardiac collapse.

Other errors and omissions are on page 130, where diverticulum of the bladder is given as a cause of obstruction at the vesical neck, whereas the consensus is that the opposite is the case; on page 212, where no mention is made of nonobstructive anuria resulting from the use of sulfonamide derivatives; and on page 249, where transurethral resection of the vesical neck is omitted in the treatment of neurogenic dysfunction of the bladder.

The author has opened a major controversy in the section on enuresis. He starts out well enough by stating that the vast majority of these cases are psychogenic in origin. In discussing treatment he says "Flee the psychoanalysts as you would the devil. The mother can furnish her own psychotherapy." How this can be reconciled with the concept that most cases of enuresis are due to a conflict between the child and the mother, and that the best results in treatment are obtained by psychiatrists, is something for the author to ponder.

In spite of the criticisms offered, this book is recommended for its personalized point of view and generally sound teaching.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

CANCER OF BREAST IN PREGNANCY

To the Editor:—A woman aged 40, with 5 living children, has a tumor in the breast. She is six months pregnant. There are no palpable lymph glands in the axilla; x-ray of the chest is negative. Suppose the biopsy should prove the tumor to be cancer; four main points of view are expressed: 1. Do nothing; let the patient have her baby; the case is hopeless anyway. 2. Do a radical mastectomy and a Porro's operation with bilateral ovariectomy. 3. Do a radical mastectomy and let the pregnancy go by. 4. Do a radical mastectomy and in about one month, when the fetus will be viable, do a Porro's operation and bilateral ovariectomy. Will you please discuss this case.

M.D., Ohio.

ANSWER.—This case brings up the problem of mammary carcinoma in the sixth month of pregnancy in a multipara who does not have evidence of metastasis to the axilla or chest.

Since the pregnancy is two-thirds advanced, abortion is of doubtful value. If the tumor had been picked up in the first half of pregnancy, therapeutic abortion would be indicated. Under the circumstances irradiation to the tumor could be given until term and then a radical mastectomy done. Following this castration by irradiation should be considered in order to prevent additional pregnancy and inhibit subsequent spread of the tumor. In a case like this irradiation given preoperatively would reduce the vascularity of the breast and inhibit tumor growth.

NEUROLOGIC SYMPTOMS FOLLOWING INJECTION OF MERCURIAL

To the Editor:—I have been treating a woman who has right and left cardiac decompensation with daily intramuscular mercupurin for two weeks. With this she also received daily oral digitalis. She improved greatly and thereafter I gave her mercupurin once a week for about two weeks. From the beginning she complained of numbness of both legs and feet, which I attributed to loss of fluid; but now she has developed right foot drop. What is the cause of the neurologic symptoms—could it be due to the mercury? Shall I continue the mercury and what shall I do? The blood count is normal.

Edward V. Maggio, M.D., Brooklyn.

ANSWER.—Foot drop can occur with intramuscular injection in the buttocks if the injection is made close to the sciatic nerve. This also could account for numbness of the legs and feet. It is rather unusual to have these symptoms with theophylline containing mercurial diuretics, because permanent tissue damage is not produced by injection such as occurs when theophylline is not combined with mercurial salt. However, if the injection is placed close to the sciatic nerve, symptoms do develop and if the nerve itself is injured foot drop might also occur. If the injection is given intramuscularly it should be given at a site well away from the sciatic nerve or the material could be given intravenously. Storage of mercury occurs to only a slight extent, if at all, with theophylline containing mercurials, so that the neurologic symptoms are probably not due to mercurial poisoning.

OBESITY, DELAYED DENTITION AND UNDESCENDED TESTIS

To the Editor:—A boy aged 10 months weighing 27 pounds (12 Kg.) and 31 inches (79 cm.) tall had a birth weight of 7 pounds 1 ounce (3,200 Gm.) and height of 21 inches (53 cm.). His weight is uniformly distributed. At 2 months of age he developed an acute right hydrocele, which diminished in a few days, becoming bilateral at 2½ months and disappearing at the age of 6 months. He is alert and active. The penis and scrotum are small. There is a tiny left testis in the scrotum. The right testis is not palpable anywhere. Teeth have not erupted. I have been considering the use of thyroid by mouth and testosterone by injection. What treatment, at what age, is advisable for his combination of obesity, delayed dentition and underdeveloped sex organs?

Leon Paris, M.D., New York.

ANSWER.—The query does not state whether this infant received vitamin D in any form. Lack of vitamin D can certainly retard dentition, and adequate amounts of this vitamin should be supplied to every infant. Unless hypothyroidism or mild cretinism is diagnosed by the aid of x-rays of the bones of the wrist, thyroid medication does not seem indicated.

If the right testicle has not descended into the scrotum by the age of 11 or 12 years, endocrine therapy and surgery may be contemplated.

FREQUENCY OF ELECTROENCEPHALOGRAPHIC ABNORMALITIES IN EPILEPSY

To the Editor:—If in all cases the electroencephalogram reveals characteristic changes in the potential or "brain wave" in epileptic patients, what percentage of cases on encephalographic study show outlines to be abnormal or essentially normal, if any?

M.D., Texas.

ANSWER.—Seizure discharges are the only abnormality truly characteristic of epilepsy. The finding of such discharges suggest epilepsy or a strong epileptic diathesis. The percentage of epileptic patients showing seizure discharges varies with the general severity and the type of epilepsy under consideration. In a random sample of 1,000 outpatient epileptic patients routine waking electroencephalograms revealed 30 per cent with seizure discharges. However, 22 per cent had exceedingly slow or fast electrocardiograms, which are suggestive of epilepsy or related organic disorder. Recent studies have shown that during sleep seizure discharges occur in 85 per cent of epileptic patients and in less than 1 per cent of controls. Therefore sleep greatly increases the diagnostic power of the electroencephalogram. However, sleep studies are not ordinarily called for unless the waking record is found to be normal or only slightly abnormal.

PATHWAY OF REFLEX FROM BURNING HAND

To the Editor:—What explanation is given when a hand unconsciously touches a hot stove and the hand is pulled back quickly? Am I right? The nerve impulse from the hand goes to the cord center and is reflexed back to the hand; hence the quick pulling back of the hand. From the cord center the message goes to the brain. Then the brain sends a message to the hand that it has been burned, and hence the pain. If not correct please send explanation.

J. Louis Waldner, M.D., Loveland, Colo.

ANSWER.—The correspondent is entirely correct that in a normal person when a hand unconsciously touches a hot stove the hand is pulled back or away from the stove immediately. This is a reflex phenomenon and it occurs almost instantaneously. The pathway for this is as follows: the fast pain fibers in the skin are stimulated by the hot stove, and the impulse travels up the peripheral nerve, the posterior spinal ganglions, the posterior root into the small myelinated and unmyelinated fibers in the substantia gelatinosa of the posterior horns. From here the neurons arising in the posterior horn cross the midline of the spinal cord into the anterior horns and then into the ascending spinothalamic tract. From here the fibers finally end in the lateral nucleus of the optic thalamus. The reason for the rapid pulling back of the hand is that the movement is one of a reflex nature, i. e. the hand is pulled away because of the rapid effect the stimulus has on the anterior horn cells. All during this time, even though it is only a second or two, the stimulus of the heat has reached the thalamus and cerebral cortex, i. e. both posterior central and precentral gyri.

FATTY ACIDS AND DERMATITIS

To the Editor:—What are the common foods that contain linolenic and arachidonic acid? What is the best method for administering the unsaturated fatty acids other than in foods or drugs? Please furnish recent references in the uses of these acids in eczematoid and atopic dermatosis.

Irwin I. Lubowe, M.D., New York

ANSWER.—The work of the Burrs (*J. Biol. Chem.* **88:**349 [May] 1929) has shown that the most essential fatty acid is arachidonic acid, but linoleic and linolenic acids are also important in fat deficiency diseases. This, however, was based on animal experiments. Other observers, such as A. E. Hansen (Serum Lipids in Eczema and in Other Pathologic Conditions, *Am. J. Dis. Child* **53:**933 [April] 1937), Faber and Roberts (*J. Pediat.* **6:**490 [April] 1935) and Finnerud, Kesler and Wiese (Ingestion of Lard in the Treatment of Eczema and Allied Dermatoses, *Arch. Dermat. & Syph.* **44:**849 [Nov.] 1941) found that the degree of unsaturation of the serum lipids tends to be low in patients with dermatitis. Cornbleet (Use of Maize Oil in the Treatment of Eczema, *ibid.* **31:**224 [Feb.] 1935) also found that patients with certain types of dermatitis were benefited by diet high in unsaturated fatty acids.

Stoesser (*J. Allergy* **18:**29 [Jan.] 1947) has described the influence of soy bean products on the iodine number of the plasma lipids and the course of eczema. He has shown that infants with severe eczema had an iodine number averaging 71, which is much below normal. However, after three or more weeks of ingestion of the soy bean milk the values rose until an average of 118 was reached, which is within normal range. This situation was associated with a favorable response to external therapy. The simplest method of administering linoleic and arachidonic acid is by the administration of soybean lecithin. This can be given to children as a milk substitute or to adults as soybean lecithin directly. It is not practical in most instances, especially since food sensitivities enter the picture, to attempt to give sufficient of these acids by means of food alone.

EFFECT OF FLUORIDES IN DRINKING WATER ON TEETH

To the Editor:—Following is an analysis of the Myrtle Beach water supply (fluorine 4 to 5 parts per million). Most of the inhabitants have dental fluorosis. When should an expectant mother begin drinking water from other sources, considering that only the permanent teeth are to be protected for fluorosis? When should she start, considering that both deciduous and permanent teeth are to be protected?

	Parts per Million
Color	10.00
Chloride	94.00
Alkalinity	540.00
Free carbonate	0.00
Hardness	0.00
Total solids	832.00
*p*H	8.3
Fluorine	4 to 5

G. P. Joseph, M.D , Myrtle Beach, South Carolina.

ANSWER.—As all permanent teeth are calcified after birth, the fluoride content of the domestic water used by the mother during gestation is immaterial. The slight signs of dental fluorosis occasionally seen on deciduous teeth are insignificant and are not sufficiently important to warrant corrective measures.

With respect to the permanent teeth, however, the picture is entirely different. The continuous use from birth of a domestic water containing the fluoride concentration mentioned can be expected to produce endemic dental fluorosis in about 90 per cent of the users. Much of the dental fluorosis produced by using a water of this concentration is of a disfiguring type.

To protect the child from developing dental fluorosis in the permanent teeth, the water used for both drinking and cooking during the first eight years of life should not contain fluorides (F) in excess of 1 part per million. This procedure will protect all permanent teeth with the exception of the third molars. If the latter are to be protected these prophylactic measures must be extended to the sixteenth year

HYDROLYZED AND UNHYDROLYZED PROTEINS ORALLY

To the Editor:—In what specific clinical conditions are protein hydrolysates superior to unhydrolyzed protein for oral feeding? In diarrhea or intestinal fistulas is the body able to absorb more amino acid from hydrolysates than from unhydrolyzed proteins given orally? For clinical purposes is lactalbumin superior to casein for supplementary oral protein feeding?

M.D., Florida.

ANSWER.—A categorical reply to the first question is not possible, since experts are not yet agreed as to whether protein hydrolysates are to be considered superior to purified whole protein for oral feeding in any condition. Elman feels that the oral use of hydrolysates permits the assimilation of much larger daily amounts of protein nourishment than seems possible when whole protein is given (Elman, Robert: *Am. J. Digest. Dis.* **10**:48 [Feb.] 1943). Kozoll, on the other hand, finds that patients cannot take many of the available oral hydrolysates because of unpalatability. Hence they must be given by gavage, which is uncomfortable and time consuming. Large amounts of protein hydrolysates taken orally frequently lead to troublesome diarrhea. Kozoll feels that ideal high protein therapy for patients able to take food by mouth is the oral administration of a palatable, easily digested protein or protein derivative susceptible of being incorporated in large quantities in the common foods (Kozoll, D. D.; Hoffman, W. S.; Meyer, K. A., and Garvin, Thelma: High Protein Therapy, *Arch. Surg.* **53**:683 [Dec.] 1946).

Theoretically, hydrolyzed protein should be assimilated more completely than unhydrolyzed protein by patients with diarrhea or intestinal fistula. Satisfactory experiments have not been performed to prove this point, and it may be more theoretical than real, particularly in view of the fact that hydrolysates themselves may produce a diarrhea.

As far as is known, lactalbumin and casein are nutritionally comparable and any differences between them are not significant from the standpoint of human therapy. More important is the manner in which the hydrolysate is produced and the actual nutritional value of the finished product as compared to the protein from which it was derived. This can be determined only by actual test.

HAZARDS OF MERCURY BICHLORIDE

To the Editor:—What is the minimum daily dosage of mercury bichloride. Will it make a difference whether it is taken orally or applied externally? What are the signs and symptoms of chronic mercurial poisoning? I have been using a hair tonic preparation with bichloride in it for the past year and a half.

Lieutenant, M. C., U. S. Army.

ANSWER.—It has been estimated that the continued absorption of 5 mg. of mercury daily in the form of its ionized salts, which would include the bichloride, may be just on the borderline of being deleterious. Compared to the other routes of entry of mercury into the organism, the cutaneous one is relatively unimportant. Laboratory experimentation has shown that under the most favorable conditions for cutaneous absorption the application of approximately 80 mg. of mercury as calomel to 8 per cent of the body surface of animals results in an absorption of the order of 0.1 per cent, or 0.08 mg. of mercury. While it may be assumed that mercury bichloride would behave similarly, it is believed that the conditions of exposure on the scalp would be much less favorable to absorption. Analysis of the urine is the best means for evaluating exposure to mercury. The excretion of 0.1 mg. daily indicates active absorption. Long-continued exposure to relatively small doses of mercury may lead to slow and insidious development of chronic poisoning. Some of the symptoms are fine intention tremors, psychic irritability, restlessness, nutritional disturbances, stomatitis and renal irritation.

PERCEPTIVE DEAFNESS AND ALLERGY

To the Editor:—I should appreciate information on the possible relationship of allergy (nasal and general) to a moderately severe perceptive bilateral deafness.

Francis E. Gilfoy, Major, M. C., U. S. Army.

[This query was referred to an otologist and to an allergist, whose respective replies follow.—EDITOR.]

ANSWER.—The following diagnostic criteria are the chief characteristic features of bilateral perceptive deafness of allergic etiology: 1. The degree of deafness tends to fluctuate. 2. There may be as much loss for the low tones as there is for the medium or high tones on audiometric examination, if not more. 3. If the loss is much greater for one ear than for the other, the ear with the greater loss may have diplacusis. 4. Improvement in the deafness by eliminating the offending allergen and reproducing the deafness after reexposure constitutes final proof of the allergic nature of the deafness. 5. If the deafness is associated with attacks of vertigo and tinnitus of varying intensity the symptom complex is known as Ménière's syndrome. While there are occasionally cases of perceptive deafness due to an underlying allergy, they are comparatively rare as compared to the total number of cases of impaired hearing of the perceptive type.

ANSWER.—It seems best to answer this inquiry on the basis of Ménière's syndrome, in which deafness, tinnitus and vertigo form the characteristic triad. In 1923 Duke described 5 cases of Ménière's syndrome caused by allergy; later Dean, Agar and Lenton and finally Jones called attention to the fact that allergy does affect the eustachian tube, the middle ear and the internal ear, even though scientific proof is lacking. Granstroem and Nylen stress the importance of allergy in the etiology of Ménière's syndrome. Thornwall and Crowe, however, could not find allergy as a cause of this syndrome. Brunner's review of the literature is all inclusive.

ADMINISTRATION OF IODIDES TO AID DIAGNOSIS OF PULMONARY TUBERCULOSIS

To the Editor:—Is a physician justified in administering iodides to establish a diagnosis in suspected pulmonary tuberculosis when all other diagnostic procedures have been negative.

M.D., Louisiana.

ANSWER.—Administration of iodides to aid in establishing a diagnosis in suspected pulmonary tuberculosis was at one time practiced extensively. When a pulmonary lesion was found but tubercle bacilli were not recovered from the sputum, large doses of iodides were administered, following which, in some cases, organisms were found in the sputum. It was thought that iodides destroy fibrous tissue in the lesion and liberate the bacilli. Therefore this procedure fell into disrepute because of the assumed danger of reactivating tuberculous lesions. Hence physicians abstained from administering iodides even for other purposes in cases of tuberculosis with well established diagnoses as well as in suspected cases. A careful review of the literature has not revealed the report of any scientific study to prove that iodides have a deleterious effect on tuberculous lesions. Apparently the numerous statements to the effect that iodides are harmful in tuberculosis were based entirely on opinion. Gross syphilitic lesions were seen to vanish under iodide therapy, and apparently it was assumed that the fibrous tissue of tuberculous lesions would be destroyed under the same treatment. Iodides may increase and liquefy secretions in the bronchial tree. Therefore it is probable that when they were used in the diagnosis of tuberculosis they only liberated mucus and other material from the region of the lesions which contained tubercle bacilli.

While apparently there is no proof that iodides are harmful in either suspected or well established tuberculosis, they are now almost never administered as a diagnostic aid. Other far more effective methods have superseded this procedure. If the patient in question does not react to tuberculin, properly administered intracutaneously and in sufficient dosage, it is certain that tuberculosis is not present. If he does present a characteristic reaction it is not definite proof that the lesion in question is tuberculous, since tuberculin reactors develop nontuberculous lesions as readily as nonreactors. If a characteristic tuberculin reaction has been demonstrated and sputum does not contain acid-fast bacilli, gastric washings should be carefully examined for them. These washings are best obtained by having the patient drink a glass of water before eating or arising in the morning. A few minutes later this is removed by a small stomach or duodenal tube and studied immediately; that is, the washings should be digested and concentrated promptly after removal and planted on culture medium or, preferably, inoculated into *guinea pigs*. If tubercle bacilli are not recovered from sputum or gastric washings, there is little likelihood that the administration of iodides will be helpful.

POSSIBLE EPILEPTIC SEIZURES

To the Editor:—A girl aged 9 years has had spells of amnesia for the past three months lasting from a few hours to a full day. She is in perfect health otherwise, which has been verified by three physicians, one a psychiatrist. She attends school regularly, is bright, plays every day, rides a bike, hikes, goes to the movies, sleeps and eats well, and all of a sudden becomes quiet, dazed, listless, has that far away look in her eyes, doesn't remember anything and answers questions that do not seem to register. After a spell she is herself again, a different child, and then asks her mother what was the matter with her. From this brief history what do you think might be the diagnosis?

M.D., Pennsylvania.

Answer.—Presumably the child is having epileptic seizures, either a prolonged psychomotor attack or periods of petit mal status. An electroencephalogram will probably distinguish which. Differentiation is important for prescription of medication, diphenylhydantoin sodium being used for the first and tridione for the second condition.

BLOOD TYPE AND PENICILLIN FAILURES

To the Editor:—Has any study of the relationship of blood type to effectiveness of therapy with penicillin or sulfonamides been made? It has been called to my attention by a chief pharmacist's mate that in his experience men with type A blood do not respond well to penicillin therapy. At the present time I have three penicillin and sulfonamide resistant gonorrheal infections under observation and therapy. Probably coincidentally, all are in patients with type A blood.

M.D., U. S. Navy.

Answer.—There is no evidence in the literature that penicillin failures are more common in patients with group A blood. In the case of gonorrhea it has been shown that many patients who were thought to be resistant to penicillin are really victims of reinfection during treatment. The prevention of sexual congress while the patient is undergoing treatment is one of the ways of determining whether a patient is resistant to a fixed dose of penicillin.

RELAPSING MALARIA

To the Editor:—A veteran from the South Seas has recurrent malaria. Quinine gives only temporary relief. What drugs can do more and where are they available?

R. W. Hartwell, M.D., Beaumont, Calif.

Answer.—There are many servicemen who continue to have frequent attacks of relapsing malaria, and treatment with either quinine or quinacrine serves only to cure each acute episode but does not prevent the recurrence of the malarial infection at a later date.

There is a new drug on the market known as chloroquine which, if taken in the dosage of 0.3 Gm. weekly, will suppress almost all clinical manifestations of this infection, although, like quinacrine and quinine, it will not cure.

UNDESCENDED TESTES AND FREQUENCY OF HERNIA

To the Editor:—Are there any statistics available on the incidence of inguinal hernia in the presence of an undescended testis, that is, is the incidence of such hernia the same regardless of whether the testis is descended or not, or is it higher when the testis is undescended? If such an incidence is higher, is it influenced by a partial descent of the testis which can be palpated but which has not descended into the scrotum?

Walter E. Fleischer, M.D., Baltimore.

Answer.—The incidence of hernia is a great deal higher in the presence of an undescended testis than when the testis has normally descended. This is particularly true in cases in which there is partial descent of the testis which lies within the inguinal canal, because with the testis in the inguinal canal it is impossible, of course, for the processus vaginalis to become obliterated. As most of the undescended testes are only partially undescended, it is justifiable to assume that every undescended testis is associated with a hernia.

TESTS FOR PORPHYRINURIA

To the Editor:—Concerning a test for porphyrinuria (The Journal, July 12, 1947, p. 986), your reply gave an excellent presumptive test for porphobilinogen but evaded the question regarding porphyrin. The reply might have advised tests devised for several levels of porphyrin excretion. Thus for normal or slightly elevated excretion, take an aliquot (100-250 cc.) of a twenty-four hour specimen (thymol preservative), add ¼ volume of acetic acid, shake out two times with an equal volume of ether, wash once with water, take out with 5 to 10 cc. of 2 normal hydrochloric acid and measure the red fluorescence intensity in a fluorophotometer. There will always be some red fluorescence. For larger amounts of porphyrin, a qualitative test consists in shaking out the ether extract, as prepared, with concentrated hydrochloric acid and carefully adding 3 per cent hydrogen peroxide. A transient green color due to chloroporphyrin hydrochloride is seen only with pathologic quantities of porphyrin. For uroporphyrin, characteristic of porphyria, it often suffices merely to add hydrochloric acid to the urine and to examine the urine under an ultraviolet lamp (better Wood's light) to observe the intense red fluorescence. In case much porphyrin is present, first add acetic acid, then extract two to five times with ether and shake with talcum, filtering off over a column of talcum in a glass tube. Wash with water, then with ammonium hydroxide. A red fluorescence in the eluate is presumptive evidence of the presence of uroporphyrin. The diagnosis of porphyria cannot be entertained unless the subject is of dark complexion.

William J. Turner, M.D., Veterans Administration Hospital, Northport, N. Y.

OPEN VERSUS CLOSED TREATMENT OF FRACTURES

To the Editor:—The reply in Queries and Minor Notes to Dr. Forrest's query in The Journal July 19, 1947, page 1058, seems to leave the whole matter of immediate accurate reduction and subsequent immobilization of fractures in too much confusion, just as so many of our textbooks on the treatment of fractures do. The point that I have been making with regard to the accurate approximation of fracture fragments, whether by direct fixation (open operation) or by indirect fixation with pins and plaster of paris casts, is that they heal better and more rapidly than fractures that are inadequately reduced or immobilized. There is also in compound fractures the additional advantage that the patient is better able to resist wound complications and infection than if the limb is left to any degree in poor position. It has been proved in my practice hundreds of times that with the bone fragments, lymph channels, circulation and nerve supply all in normal position the physiology of the limb is better, resistance to infection is better, and healing takes place more rapidly.

A defect in Dr. Forrest's question and in your reply is one common to many discussions of fracture treatment. One must think not only of the fracture fragments, but of the limb as a whole and of the patient. Another point is that in some open reductions, excellent otherwise, too much surgical trauma or operative infection militates against a good result.

H. Winnett Orr, M.D., Lincoln, Neb.

POSTCOITAL HEADACHE AND LOSS OF MEMORY

To the Editor:—In The Journal June 7, 1947, page 563, both the question and the answer on this subject failed to bring out the cardinal points. It is necessary for a better understanding for the patient's physician to consult with urologists and internists as well as with psychiatrists. Urologic experience proves that patients apparently mentally normal otherwise will deliberately deceive their doctor about their drinks, smokes and venery. I can recall several patients in my practice who have symptoms of headache following coitus who were promptly cured by such simple urologic treatments as (1) prostatic massage for a case of chronic prostatitis and (2) passing of steel urethral sounds in a case of multiple small penile old Neisserian urethral strictures. I recall other persons who were promptly cured by ceasing to withdraw to avoid pregnancy and another who was also cured when advised to stop using condoms for contraceptive purposes. The former cited cases were undoubtedly urologic, whereas the latter two were probably largely psychic. My advice to this inquirer is to seek the consultation of a good urologist. It is always necessary to find the cause; apparently the basis of this patient's trouble is urologic.

Paul R. Stalnaker, M.D., Capt. (MC), U.S.N. (Retired), Houston, Texas.

THE NEUROLOGIST LOOKS AT DISCIPLINE

Chairman's Address

ROLAND P. MACKAY, M.D.
Chicago

The neurologist, like every other man, must be his own philosopher, must step back and survey his daily life and work and consider their meaning and implication for the world around him No serious and candid man, least of all the neurologist, can ignore the varying human scene or fail to consider it in the light of his special knowledge and training. The problem of democracy—how man can live in peace and good will on a crowded and shrinking planet—demands solution. The problem of the individual—how man can live in happiness with himself—is to be resolved. It has been said that ours is a uniquely neurotic time in history.[1] Whether this be true or not, ours is indeed an age of unreason,[2] with its conflict and bitterness, its fears and hatreds in peace, even greater than in war, its starvation amid plenty, its keen personal discontents.

Often immured in his hospital or clinic, the neurologist is nevertheless conscious of these matters and has something to contribute to their solution. He knows that the nervous system is the organ of civilization, that the facts regarding higher neurologic integration are pertinent to our social and personal dilemma. He is equipped by his background and education to study the formation of human character and, unlike some of his scientific friends, to approach without mysticism the genesis of human personality and its deformities, the neuroses. He must speak his mind.

Now, while the neurologist makes no pretense to a comprehensive solution of the ills of mankind, he does know that the great trouble with the world lies in the perversity and contrariety of human behavior. He can testify, further, that these perversities arise not from intellectual but from emotional forces in the individual. Virtue is not born of knowledge, nor vice of ignorance. In the words of Shakespeare: "If to do were as easy as to know what were good to do, chapels had been churches, and poor men's cottages princes' palaces." The determinative emotional forces in behavior are compounded out of the original self-preservative and race-preservative impulses of the individual. If they are deformed into patterns of fear and hatred and aggression, it is not in formal education, but in the complex personal impact of parent and society on the child.

Thus, our first principle is that of Wordsworth: "The child is father of the man." This is not new, but it is just as true as if it were the latest discovery of atomic science. If man is unhappy and perverse, if he entangles himself in his own conflicting desires, if by some vicious alchemy he transmutes his love into hate, if he persistently seeks satisfaction in his own destruction, if he paralyzes himself with his doubts and indecisions, if he is unable to sacrifice an immediate and spurious advantage for a great ideal, if, in short, he stubbornly strives to gain the whole world but loses his own soul, it is because in childhood he has been molded to futility by his parents and by society. If the behavior of the individual and of society is "neurotic," that fact can only mean that the training of the youth has been a failure. The prevention of such behavior (for "cure" is difficult and uncertain) can only be achieved by a study of childhood and its discipline.

Fortunately, we are no longer dependent on empiric systems such as theology, sociology, armchair philosophy or even couch psychoanalysis for our understanding of the processes of learning and the establishment of the neuroses. Instructive as these systems have been, some founded on long ages of human experience, they have produced only a discordant babel of strident voices. Witness the "to spank or not to spank" controversies, the doctrines of "self expression" and the puerile debates over the weaning and feeding of babies, the waywardness of youth and sex education, both in and out of schools. Leaving aside such confusing counsel, one may turn instead to a body of carefully controlled experimental evidence on the formation of habit and the production of the neuroses in animals. Limited though these data at present are, they represent the early fruit of our first objective approach to the molding of character and to its distortions, the neuroses. At last a little experimental evidence is available, free of the suppositions and mysticism of centuries of superstition, not yet at an end.

As the reflex arc is the physiologic unit of the nervous system, so the conditioned reflex is the physiologic unit of character. From the work of Pavlov and many others we have learned some of the laws by which original or instinctive responses expand and flower into the complicated "acquired" behavior of the organism. These laws are so constant and verifiable that they must apply with equal force to the human being, albeit in greater complexity. What is even more important, we have learned some of the circumstances in which neuroses may be experimentally produced in an animal during the establishment of conditioned

reflexes—neuroses which exhibit in simple form many of the characteristics of the human neuroses.[3] Many of the laws governing these processes are well known and cannot be ignored in any theory of human behavior.

It is the purpose of this discussion to examine a few of these principles and to apply them to the problem of the discipline of children. One fact, as it were an axiom, is essential to our discussion: viz., that it makes a great difference whether and how we discipline our children. It is strange, but there are those who still hold to a doctrine of "maturation"—the theory that children simply mature into well adjusted adults if left alone, the process by which Topsy "just growed." This hypothesis, perhaps attributable in part to John Dewey, may hold for bees but certainly not for boys and girls. For if the intellectual heritage of civilized man must be carefully and diligently offered to the young in formal schooling, surely the more subtle and fundamental traits of character must be as carefully fostered. To allow a child to acquire his character by "maturation" is simply to let him acquire it by the fortuitous impact of events. Such a policy, admittedly followed by many parents today, is the apotheosis of neglect. If one must train a good hunting dog not to devour the bird he retrieves, how can one escape training a boy to be an honest and charitable and tolerant man?

THE OBJECTIVE

For the establishment of conditioned reflexes in an animal, there must be a definite objective. One must, in short, have something to teach—a set of reflexes to establish. This is no less true in the training of children. Modern parents fail oftenest here. Living an emotionally hand to mouth existence themselves, believing consciously in nothing beyond a materialistic opportunism, many deal with their children opportunistically, as the emotion of the moment dictates, for their own comfort and convenience. Such parents are captious, by turns demanding and lenient, having no major principles of life for the government of their own prejudices and whims. Such a policy is indeed the abdication of parenthood. If our civilization has any standards by which it lives, any qualities which in an earlier day were called spiritual, these standards and these qualities must be transmitted to our successors, or our culture dies. Our society has a body of ethic, carved laboriously out of the ages of human experience, and this ethic, certainly not static, certainly under constant evolution, is nevertheless fundamental. It includes honesty, the love of truth, devotion to duty, loyalty, courage, diligence, unselfishness, respect for just authority and tolerance and concern for the rights of others, which is the soul of democracy. These virtues, perhaps "old fashioned" in our modern acquisitive and amoral times, are merely examples, by no means all inclusive, of the character traits, of the "conditioned reflexes," which are available for the rearing of our children. They are a few of the virtues underlying emotional maturity, underlying a gracious and tolerant civilization. To fail to impart them is to abandon our children to a poverty of great ideals and a preoccupation with self which lie at the root of our personal and social neuroses.

Given such a heritage of virtues, what can we say about the rules of their transmission to the young? What can we say about discipline?

LOVE AND HOSTILITY

For the establishment of conditioned reflexes a friendly environment is essential. Affection and kindliness toward the animal are indispensable. Every laboratory worker knows this to be true. And for the successful rearing of children, love is the prime essential. It is the great unconditioned stimulus on which is based the whole training of the child. In modern life children are often unwanted and receive much hostility from their parents. Once an economic asset, children are now for many an impediment in the struggle for material advancement. Particularly for their mothers, "emancipated" from much of their former sacrifice of time and effort for their children, seeking personal significance in a harshly competitive world, and fleeing into narcissism, babies represent a handicap.[1] Women no longer derive prestige from motherhood as they once did. A woman with more than two children is too often commiserated with or looked on as slightly stupid by her less fecund sisters. For their fathers, children mean less financial savings, less luxury, less golf, less time for their own pursuits. Children tend to lock the door of escape from marriage in a world of promiscuity and divorce. Furthermore, the husband is adversely affected by the discontents of his wife who, despite her "emancipation," considers herself a "drudge" because of their children. In this age of the all but unobtainable "sitter," both mother and father find their pleasures limited by their children.

Whatever the reasons, children are too often secretly or openly hated by their parents; they are therefore neglected, ignored or subjected to a suffocating tyranny of restrictions only thinly disguised as parental concern. The selfish tycoon of business, the harried professional man who must spend his evenings with his work or his books, the playboy who cannot renounce his night club, have no more time for their children than the social-climbing mother, who is more afraid of "dishpan hands" than of neglected children. Thus hostility colors every parent-child relationship, and is immediately sensed, even by the infant.

The results are promptly evident. The child responds to hostility with hostility and fear. Such ideals as the parents have to give are at once rejected. Worse, the neglected, unloved youngster learns to regard the world as an unfriendly place, grows ever more hungry for affection and attention and responds with fear under a sense of insecurity. Fear attaches itself to whatever objects, persons or events may be present; undesirable conditioned reflexes are established apace. The child's attitude toward his hostile and neglectful parents disturbs his relationships with both the same and the opposite sex and insures the frustration of his sexual adjustments. In such emotionally charged circumstances, no proper training of the child can occur, and his character is warped and distorted.

One sociologic fact suggests a partial remedy for this regrettable situation: No one who does not want children need have them. Contraceptive measures, whether by rubber or by the ecclesiastic calendar, insure that parenthood may be voluntary. Perhaps we see the dawn of the day when only the lovers of children will beget them.

EXAMPLE

Such parents, loving their children, must set an example of the virtues which they would impart. Their children, welcome and secure in a friendly environment, will imitate the virtues which their parents exhibit. It

---

3. Masserman, J.: Principles of Dynamic Psychiatry, Philadelphia, W. B. Saunders Company, 1946.

is well known that an untrained animal, placed with one already possessing complicated learned reactions, will become conditioned more rapidly than if alone. And any father knows full well the power of imitation over a small son who is loved. Thus a truthful, kindly, self-controlled, scrupulously fair parent has a son, provided that he love him, who is truthful, kindly, self controlled and fair. Thus a mother who keeps her home in careful order will have a daughter, if love be present, who soon comes to hang up her clothes and make her bed and who eventually keeps an orderly mind.

REWARD AND PUNISHMENT

Reward and punishment determine all behavior patterns. The random movements of the infant which bring gratification are facilitated; those which fail or bring distress are inhibited. The rat solves the maze because only when he follows the correct path does he get the cheese. The boy masters the bicycle because only the correct movements give the exhilarating ride. False moves bring disaster. Thus do motor skills evolve through survival of the fittest acts. The key is gratification in return for the correct response. The corollary is punishment for error.

Skills in human relations grow under the same law. A successful personal contact is one which brings approval and admiration; an unsuccessful one brings dislike and hostility. It would seem that the complex interactions of social life develop from an elaboration and subdivision of this simple formula.

It is the province of parents and society to utilize reward and punishment to build into the child those virtues which they cherish. Every child is entitled to feel important or essential, to have his behavior approved and admired, and to be loved, but, so far as lies in their power, parents and society must accord these gratifications in return for virtuous behavior. To allow a child to obtain such rewards by indirection, subterfuge and falsehood, or by playing one parent against another, is to establish habits of deceit and dishonesty. Other vices may be similarly inculcated by similar tactics.

In order to receive the approval and admiration of his parents, every child should have what is often difficult to supply in modern urban life: tasks to perform in the home which are of value to the household and which, when well performed, earn for him the sense of a job well done. Thus he learns to feel necessary and valuable. Thus he sees illustrated early in his life the oft forgotten axioms that benefits must be earned and that it is shameful to have one's load carried by another. Furthermore, when useful work is required of each child he has the opportunity to learn what is one of the great lessons of life—that achievement, the successful accomplishment of a task, requires a prompt attack and the persistent application of one's best efforts until the work is finished. Promptness, diligence and thoroughness should be demanded by the parents as the price of their commendation.

It is of superlative importance that admiration and approval be awarded, not to the person of the child, but to his handiwork. Whether his virtue be the telling of the truth, the able performance of a duty, the exhibition of tolerance, or any other excellence, it should be the deed, not the child, which receives the praise. Thus one may avoid establishing the narcissistic self absorption which is at the root of much neurosis. Thus the child may learn to take his delight in his achievement rather than in himself. Thus may be fostered the urge to do well rather than to be personally admired. In this way perhaps undue personal attachments to one or the other parent may be avoided, with their attendant disturbance in his psychosexual development.

The problem of punishment is often more difficult than that of reward. One should allow, if possible, the penalty to follow a misdeed naturally. This means that the advantage sought through the misdeed must be withheld. Play won by neglect of a duty must be forbidden. The fruits of deception and falsehood must be denied. Not infrequently, no deprivation can be used, and corporal punishment must be applied, particularly in the very young, for whom more abstract punishments have little meaning. But the manner in which a child is spanked is of greatest importance. To lash out in anger makes the punishment but a form of assault. The parent's position here is difficult, for he must be both accuser and judge. It is only with scrupulous justice and fairness, and avoidance of hostility to the child, that he can impose punishment as the regrettable verdict of impersonal law. Far from being an insincere pretense, the old, oft ridiculed statement, "This hurts me more than it does you," is an exact expression of the feelings of a conscientious and affectionate parent. One must "hate the sin while loving the sinner."

The truth is that spanking has fallen into disrepute because of its abuse by vengeful and guilty parents who project their own guilt onto the child. What lazy father can spank a lazy son except in anger? What untruthful mother can punish her little girl for a lie unless in hostility? Thus, only the pure in heart should spank a child. With this reservation, and with the further proviso that after the punishment the penalty be considered as paid and the child be reaccepted in good favor, corporal punishment, as an isolated event, is infinitely preferable to the constant nagging and belaboring which, to a practical youngster, soon come to mean nothing but hostility.

CONSISTENCY

Conditioned reflexes cannot be established unless the stimuli remain constant. To impose one set of restrictions today and another tomorrow is to achieve no results. The intelligent child, so handled, is confused rapidly becomes intolerant of any deprivation or punishment and shows understandable fear and hostility toward so capricious an authority. Such circumstances produce neuroses in animals; it seems reasonable that they do also in the human being. It is as if a child had to learn to walk under laws of mechanics which changed from day to day. With these facts in mind, it is obvious that the rules of behavior should be mild and kindly enough to be enforced regularly and consistently. To forgive a child for lying is to teach him to lie. To punish cruelty and injustice one day and condone them the next is to teach cruelty and injustice.

If two experimenters are working with the same animal, they must follow the same rules. In the training of children there are normally two (and sometimes more than two) experimenters. The possibilities of inconsistency are thus almost limitless. Standards imposed by one parent may not be required by the other, and when the parents agree the grandmother may, and often does, disagree. When two parents are mutually hostile and compete for the favor of the child, or when they dispute his discipline in his presence, he learns quickly enough to play one against the other.

In the end he becomes a dissimulator, operating in fear and hatred, holding all authority in suspicion and contempt. He learns to get his way by cynical diplomacy. Such a child, doomed always to ignorance of the law and finding the authority of the home divided, never achieves a sense of security. For him the domestic world is an unfriendly and arbitrary place, where reward and punishment are scarcely to be distinguished. Thus, it is ideal for parents to have similar cultural, ethical and philosophic backgrounds. When they nevertheless disagree, the child must be shielded from their words of disagreement.

PARENT AND SOCIETY

Finally, we must remember that parents, vouchsafed the first word with the child, do not have the only word, or the last. The unit of society today is scarcely the home, poor and forsaken thing that it is, but rather the community of associates among which each person moves. Often the home is little more than the point of departure from which young and old leave for their several amusements. Our contacts with our children are thus progressively reduced almost to the vanishing point. Other parents who, for their ease and convenience, allow their children to grow without guidance, compete with us in influence over our offspring. Our neighbors' children, bringing the ideas and ideals of their own circles, play a great role in the shaping of the concepts and philosophy of our young ones. Besides the impact of their own opinions and behavior, they begin by taking our children with them to the motion pictures, continue by inviting them to the dance hall and eventually lead them to the night club and the tavern.

In this frenetic and commercial age, not only our children but all of us are wooed by a host of forces answerable only to the desire for profit. Whatever their wares may be, from soap to sentiment, they stimulate and appeal to every instinctive and primitive need, if only we will buy. Thus we—children and all—are constantly drawn toward ethical and philosophic sensualism.

For example, consider the influence of the motion picture in the decay of esthetics and in the decline of morals. Witness the cultivation of the garish and the ostentatious, the vulgarization of feminine beauty, the constant disparagement of hard work in favor of smart subterfuge or outright banditry and the routine use of wealth as a measure of success. As for sex, various degrees of seduction in polychrome instruct the fantasy of the boys and girls who sit in mutual proximity in a merciful darkness. The motion picture is the greatest "educator" of all time, with its vivid sensory impact, its emotional dynamics and its mass appeal. How can parents equal or combat such tutorial efficiency?

But this, though much, is not all. How can a parent compete with the unwearied radio, with its perpetual vaudeville, its spine-tingling murders, its mawkish sentimentality, its passionate commercialism? How can a parent protcet his child from the daily parade of criminal and sexual psychopathology in the newspapers, repeating in every edition the edifying story, for example, of how a little girl was dismembered and scattered over a city? Or protect them from the saltier details of Hollywood's decadency? Or from stupid comic books, for that matter?

The answer is not forthcoming. Perhaps the best that we can do for our children is to offer them a better fare of ethical, esthetic and intellectual food, to exemplify in our own lives the virtues and excellencies which we would have them possess. If we have avoided that great enemy of discipline, hostility, if we have established our authority by its kindliness, reasonableness and yet inflexibility, if we have striven early enough, patiently enough and constantly enough, perhaps we shall not fail.

EMANCIPATION

Since the end and purpose of discipline is self discipline, since we would, with wisdom, emancipate and not enslave our children, our most urgent duty is a progressive relaxation of our authority. Each newly won victory for the child must grant a new responsibility and a new independence. As the infant who has learned at last to walk must be allowed to walk, so each child who has learned to think must be allowed to think. The great, all-inclusive conditioning of our children must be the conditioning to self sufficiency. The reward is self respect and self confidence. This training in independence must not be reserved for the last; it must be begun early and continued daily in specific detail. Every child must be expected to exercise his own choice in each matter as soon as his choice is possible, and at whatever cost to the parent. Neither the tyranny of selfish love, which suffocates with protection, nor the tyranny of selfish discipline, which strangles with restraint, has any place in the training of a child. In this age of small families, when the identification of the parent is concentrated in one or two children, there may indeed be some justification for the current diatribes against poor "mom." The irresolute, dependent, clinging child is at times the product, to be sure, of the emotionally starved and possessive mother, who insists on living for herself the lives of her children and who passionately resists setting them free. But one may well doubt the existence of such mothers or fathers in any significant numbers. For the curse of the modern home is the neglect of children by parents who are too busy with their own pursuits and self gratification to trouble themselves with their care. Neither neglect nor domination can be justified; neither should be condoned. For the clear and urgent duty of the parent can only be the loving and steadfast training of the young and their progressive emancipation from the bonds of their immaturity.

THE RESULTS

What may we expect to result from the conscientious application of the disciplinary principles here offered? Shall we produce only a race of (Heaven forfend!) "perfectionists?" I think not. Compulsive perfectionism probably does not result from such factors. And it is well to remember that a measure of perfectionism is the indispensable ingredient of our culture. Without it we should never have had a science, an art or a literature. We should have been denied the achievements of those incorrigible perfectionists, Galileo, Kepler, Newton, Darwin, Einstein. Without perfectionism we should never have had a microscope or penicillin. We should never have seen a Mona Lisa or heard a Fifth Symphony, and we should have missed the teachings of Socrates and the Christ.

But may we not hope, through such discerning discipline, to transmit to our successors something of a moral civilization? May we not win for ourselves and our children such self discipline as may permit the social adjustments which mankind so needs today? May we not give our children an ideal of the perfectibility of human relations and a tool for its slow but sure achievement? I believe that it is not impossible. Perhaps then we shall no longer hear the vain wish for science to take a holiday until man can learn to live in good will with his fellows. Perhaps, both as individuals and as a people, we shall be happier. And perhaps, as parents, we may win the reward of the good woman of ancient times, of whom it was said, "Her children arise up, and call her blessed."

SOME APPLICATIONS OF PSYCHIATRY IN GENERAL MEDICINE

DALE GROOM, M.D
Rochester, Minn.

The internist or general physician, in dealing with the common psychogenic illnesses of his patients, has several advantages over the psychiatrist: he generally sees them in earlier stages when they are more amenable to treatment, he is in a better position to relate symptoms to the overall somatic status, and he can approach the patient as an internist rather than as a psychiatrist. Only a small percentage of neurotic patients can be or need to be seen by the psychiatrist. The majority of them, including the many new thousands who appear as part of the aftermath of war, will continue to be treated by physicians in other fields of medicine. And it is becoming increasingly apparent that a greater integration of basic psychiatric concepts with the general practice of medicine is essential if the average physician is to manage effectively this "other 50 per cent" of his medical practice. For the psychiatrist who attempted to practice without an adequate knowledge of general medical principles would be no more vulnerable to gross errors of diagnosis and management than would the internist who had only a vague acquaintance with fundamental psychiatric principles.

Just why the study of man's mental processes has lagged so far behind the study of his physiologic and chemical processes, his anatomy and the organic pathologic changes to which his body is liable, is a matter of some historical significance. Each of these fields is an avenue of approach to the same patient. Each field is limited by the narrowness of specialization and is most useful when integrated with the broader, more comprehensive, truly clinical approach, in which it is possible to see the part in relation to the whole. But because mental factors are less tangible and less amenable to measurement and manipulation, possibly because of certain deep-rooted superstitions and dogmas or the inherent nature of the human mind itself—whatever the historical reasons—the role of mental processes in health and disease has until recently been so far overshadowed by the tremendous nineteenth and twentieth century advances in bacteriology, physiology, biochemistry and the other basic sciences as to become almost obscure. And the study of man's real element of distinction from the lower animals has been left to a small group of investigators whose observations and useful knowledge have just begun to be incorporated into general medical practice.

Psychosomatic medicine, while actually not a new concept, is placing new emphasis on the relationship of psyche and soma and their mutual reactions in disease processes. The psychosomatic approach recognizes that what patients do and feel are facts no less than are the physical conditions observed in the same patients. Emotional reactions of love, fear, anger and hate are real as are the organs of the body and are capable of producing prolonged, disabling, almost intolerable illness—even death. A pathologic anxiety can cause far more suffering than the rheumatic cardiac lesion or the uterine fibroids which a patient may have (as many converts to the various healing cults can testify). Prolonged emotional disturbances are being recognized as potent etiologic agents, as bacteria are recognized, in the production of certain organic diseases. In so far as the broad aim of medicine is to prevent and relieve suffering, psychogenic illnesses deserve their share of consideration by the physician.

APPLICATIONS OF PSYCHIATRIC PRINCIPLES

Of what actual value is an understanding of fundamental psychiatric principles to the average physician in his practice?

The types of patients fall conveniently into two main groups: those in which the primary problem is that of physical illness and those in which the outstanding feature is psychiatric illness.

In the presence of physical illness the patient's reaction to his organic disease may aggravate, obscure or prolong it. For the physician to be able to rule out a neurosis in favor of an organic diagnosis or to make a positive diagnosis of a neurosis coexistent with organic disease may be essential to the correct evaluation of the medical data. A broader consideration of the patient as a whole may temper the treatment of his disease in such a way as to "not just add years to life but life to years." (As one patient observed while struggling along on a particularly strict medical regimen, "You don't really live longer—it just seems longer.")

Psychiatric illness afflicts the largest single group of patients. While they occupy more hospital beds than all other groups together, most of them are not in mental hospitals but are frequenting physicians' offices to complain of innumerable and bizarre psychogenic symptoms. The time demanded by these patients often can be reduced in the long run by effective management. The psychotics, the potential suicides and others who require hospital care by the psychiatrist must often be discovered early if serious consequences are to be averted. The common neuroses, reactive depressions, involutional melancholias and other emotional disorders amenable to treatment should be recognized as such, and their victims should be treated for their actual mental illnesses rather than for some incidental or nonexistent organic discrepancies, "diagnostic placebos," which may serve as foci on which the false symptom patterns ultimately can become fixed beyond accessibility.

This paper is an attempt to synthesize, in nontechnical language, the fundamental concepts of psychiatry that seem most applicable to all the other fields of medicine in which patients consult physicians for help.

Further material was garnered from lectures given to medical officers of the United States Navy who were under instruction in neuropsychiatry at Philadelphia during World War II, particularly from lectures delivered by Drs. Kenneth E. [illegible] ker and Earl Bond. Other sources include the [illegible] enninger, Franz Alexander, Alexis Carrel, Grego [illegible] and others.

Sources of the m [illegible] y. Much of it was derived from a series of lect [illegible] in General Practice," given under the sponsorship of the Commonwealth Fund at the University of Minnesota Postgraduate Center, April 1 to 13, 1946, by a faculty of speakers including Drs. John Romano, Professor of Psychiatry, University of Rochester School of Medicine; Douglas D. Bond, Professor of Psychiatry, Western Reserve University School of Medicine; Walter Bauer, Associate Professor of Medicine, Harvard Medical School; Henry W. Brosin, Professor of Psychiatry, University of Chicago, the School of Medicine; Thomas A. C. Rennie, Associate Professor of Psychiatry, Cornell University Medical College; John M. Murray, Consultant Psychiatrist, Dartmouth College and Massachusetts Institute of Technology; M. Ralph Kaufman, Psychiatrist, Mount Sinai Hospital, New York; Donald W. Hastings, Professor of Psychiatry, University of Minnesota Medical School, and Harold G. Wolff, Associate Professor of Medicine and Associate Professor of Psychiatry, Cornell University Medical College.

To the foregoing might be added a third group, that of psychosomatic illness, in which evaluation of the mental etiologic factors should parallel study of their organic sequelae.

Obviously, the future of psychiatry lies not so much in the salvage of the 1 million patients who crowd mental hospitals as in the applications of psychiatry to all patients. And perhaps in this atomic age when such questions as "Is the human mind outmoded?" are arising, this relatively young branch of medicine may be increasingly looked to for contribution toward the solution of problems of social as well as medical significance.

Then, too, from the physician's personal point of view, an at least cultural knowledge of psychiatry has something to offer: in a more rational appreciation of his fellowmen, in human relations, in a better understanding and perspective of himself and possibly in the matter of some aid to personal development. Finally, there is something to be said for its downright interest, for a patient's mind can be as interesting as his colon.

THE PSYCHIATRIC APPROACH

Many of the old-time physicians, though they lacked modern scientific knowledge and instruments, used effectively principles that twentieth century psychiatry has organized and delineated. Such men were known for their mastery of the art of medicine. But too often, perhaps, attempts to deal with patients who present psychiatric problems are unorganized, amateurish and not sufficiently objective. The physician who is unfamiliar with the mental mechanisms of these patients understandably feels somewhat insecure and prefers to play the game on his home field in terms of exclusively organic studies. Or he may allow his own emotional reactions or "hunches" to tinge his professional judgment. Or, as so readily happens, the obvious, superficial problems in the patient's complaint may be taken for the basic etiologic factors which they obscure.

In the average medical practice there are the patients who utilize physical symptoms (or children) as calling cards to their physicians. There are the patients with real organic disease who manifest a pseudoinsight into a pseudoneurosis because they are unable to face the implications of their actual disease. There are the true psychopaths with their characteristic impulsiveness, lack of emotional response and inability to learn from experience. And there are the often highly successful manic-depressive personalities, the odd schizoids and schizophrenics, the agitated and depressed persons with involutional melancholia. In evaluating the physical symptoms and the psychiatric disturbances of these patients, even a brief psychiatric history is usually far more reliable than mere personal impression.

An effective technic of obtaining the really significant data in a psychiatric history saves much time that might otherwise be lost in dealing with superficialities. Generally the physician is passive at first, allowing the patient to feel free to divulge relevant material, implicitly acknowledging the value of what the patient brings to the interview. Simply a noncritical attitude, by virtue of its rarity in human relations, may foster release of considerable suppressed material. In the development of an effective technic certain aspects of the physician-patient relationship deserve special consideration: the elements of initial intimidation, defensiveness and mutual distrust, which are present in any strange situation; the necessity of meeting on a mutually understandable level; the emotional factor which can catalyze or impair all subsequent therapeutic efforts, and often an unrecognized symbolic relationship (such as the patient's identification of the physician with a parent or authority), which may be utilized in treatment. An aggressive, sleuthing approach tends to put the patient on the defensive; on the contrary, an initially passive, noncritical, interested manner instills confidence and develops rapport. Psychiatry would caution:

> Don't immediately plunge into the depths of the patient's problem. The instinctive reaction to this is one of defense and evasion.
>
> Don't begin by offering excessive or unwarranted reassurances. The intelligent patient usually can see through a pollyanna attitude on the part of the physician and will resent it because it tends to belittle his problems; this leaves him with the impression that the full import of what he may feel in his strange, intolerable, unreal inner world has not received due consideration.
>
> Don't be autocratic. With only a few highly dependent, submissive persons is this approach ever effective; certainly to most of them it is unacceptable.
>
> Don't fall into the easy trap of considering that all patients must always overevaluate the physician. One must be able to allow for the fact that all emotions—love, anger, fear and hate—are part of normal development and are inherent in all human relations; that even the admiring patient has a latent hostility which may come forth in subtle resistance or overt belligerency. (Indeed, some patients seem to need only a neutral screen on which to display their unpleasant hostilities; they lose their symptoms when this is afforded.) It is helpful to learn to deal with this hostility, this negative emotional component in the physician-patient relationship, much as the clinical pathologist learns to handle offensive excreta. On analysis, such hostility usually is directed not at the physician personally but at the parent or authority which he symbolizes to the patient.
>
> Don't forcibly unwrap a patient without having some idea of his mental anatomy and without knowing how to wrap him up again. As one psychiatrist put it: "Don't do a mental laparotomy and leave the incision gaping open." The neurotic personality has defenses that have been built up carefully and often precariously, which serve the useful purpose of protection against the ravages of anxiety, guilt or fear. Patients are readily made worse—even overwhelmed—if these defenses are abruptly knocked out before adequate supports have been evolved to replace them.

Guiding the interview economizes on time and is usually more satisfactory than pushing the interview. Questions such as, "Would you like to tell me about ——?" invite the patient's cooperation and avoid the semblance of grilling. Direction and amplification of what appear to be significant facts in the history may be obtained by such comments as, "I'm interested in this —— that you mentioned." Then listen—attentively, sympathetically and uncritically—and the patient ultimately will display his real conflicts in vivid, enlightening detail.

Interpretation of the psychiatric history and observations is essentially analogous to interpretation of the medical history and physical examination in that it involves a knowledge of what might be called psychophysiology (the mental mechanisms operating in all persons) and of psychopathology (the specific mental disease states) in addition to the judgment derived from experience. Beyond this, psychiatric study places a special premium on the ability to deal with abstractions. A certain inherent sensitivity and intuition enables the astute clinician in his study of his patient to "hear the music he sings as well as the words he speaks."

The patient and his problems must be interpreted objectively. The more unresolved conflicts the physician himself may have, the less able he is to consider objectively those of others, tending instead to interpret them in terms of his own. He should not be actuated by any of his own needs for authority, for prestige or for delving into other people's lives—factors concerning which he must, to a healthy degree, be self critical.

MECHANISMS IN NEUROSES

Psychiatry believes that there is a causality in mental disease, that the neurotic patient is not just an unfortunate victim of bad fortune but that he retreats into his illness through stages which can be studied and whose course may be predicted. Mental illnesses tend to fall into patterns, which permit classification under diagnoses. The neuroses, afflicting as they do that largest single group of patients, are of major interest to the average physician.

A neurosis arises in a person as the result of the stress to which he is subjected acting against his intrinsic mental and emotional stability. This stress is either internal (due to conflicts arising from feelings of guilt, hostility or frustration) or external (due to the trauma of war, shock, grief, economic threat or environmental insult). Factors of emotional significance are generally more potent in producing stress than are those of a purely intellectual nature, and any personality will break down if this stress is sufficiently great. Against stress is aligned the subject's mental stability, which is comparable to his physical resistance to infections and which comprises his emotional maturity, his hereditary assets, his physical health and the sum of all the earlier cultural and intellectual influences stemming from his home and environment. These are his bulwarks against stress. When they are exceeded, the equilibrium fails and compensatory mechanisms that are basically neurotic are mobilized.

But obviously not all neurotic mechanisms are destructive. To a great extent they do compensate for failure; compensate in terms of adjustment to the problems that precipitate them or in terms of the drive to overcome them that is often recognized as ambition, or in terms of achievement in business or science, in marriage or the arts. It has been contended by philosophers that civilization itself is essentially a neurotic product in that it necessitates the thwarting of many primitive drives, including the aggressive ones which now and then break forth in waves of war as civilization fails, admits defeat and settles its problems by primitive force.

In the patient, too, it is this decompensation, or sometimes overcompensation to a pathologic degree, that attracts attention to the fundamental disorders beneath. Symptoms, whether they be expressed as complaints or abnormal behavior, then indicate that the mechanism has failed or has exceeded what is generally regarded as normal bounds. Then the personality is said to be sick. Help from relatives, friends, physicians or perhaps cultists may be sought in the patient's effort to restore a satisfactory balance. Or he may continue to live his disordered life, more or less conspicuously; he may develop a peptic ulcer, become an alcoholic addict or a miser, complain of innumerable physical symptoms, seek unwarranted surgical procedures, change jobs or wives or physicians or try suicide. All are familiar manifestations of uncontrolled anxiety.

Because it furnishes the power by which the subject may be carried to the often unreasonable extremes of neurotic illness, anxiety has been called the motor of neuroses. It arises in conflicts, and it drives toward their solution. Normally it is useful. In acute stages it may go on to panic. Chronic anxiety constitutes a threat to both mental and physical integrity and is apparent by its effect on the personality (nervous tension, depression, irritability and insomnia) or by psychomotor restlessness and tremors. Anxiety frequently can be observed objectively, even can be measured, through its autonomic overflow into tachycardia, pallor, dilated pupils, hyperhidrosis, changes in blood pressure and gastrointestinal dysfunction. Focalized, anxiety produces phobias or "organ neuroses." Generalized (the so-called free floating anxiety), it becomes a vague, disturbing tension capable of alighting on any convenient symptom.

Psychiatry has elucidated some of the mental mechanisms by which the personality copes with anxiety. These mechanisms are universally present both in health and disease, as are metabolism and peristalsis, but they may become disordered in mental illness. Rarely are they found in pure culture; usually combinations of them go to make up the psychopathologic process of a neurosis. Their value to the clinician is that they help him bring order out of the seeming chaos of symptoms, motives and conflicts which his patient presents. Some of the more commonly encountered mental mechanisms deserve special consideration:

Evasion.—This is a simple circumvention of the anxiety-producing factors. Relaxation, travel, daydreaming, the use of alcohol—all bring temporary respite which in pathologic degree can constitute neurotic evasion. The alcoholic, the hermit, the professional clubwoman intent on her busy idleness, the vagrant, the fanatic on hobbies or religion—most of these familiar characters are readily seen to be evading some highly distasteful problems. And since physical illness is regarded as the perfect excuse for nearly any failure, physical symptoms often serve the same evasive purpose. (It is doubtless true that many persons with strong fears of organic disease avoid medical examinations because in some irrational subconscious way they sense that as long as the disease has not been diagnosed they do not have to face the thing they fear.)

Regression.—Essentially a turning backward, regression implies a withdrawal such as the ameba displays when it withdraws its pseudopods from an unpleasant stimulus. In a regressive mechanism a person reacts to his problems in a way not commensurate with his degree of maturity, whatever that degree may be. Instead, he retreats to the security of earlier, more deeply ingrained patterns of behavior: the impulsiveness or competitiveness of adolescence; the thoughtlessness, dependency, pouting, magic-thinking or irritability of childhood; even the complete, demanding selfishness of infancy. Emotion that through normal development had been invested in interests outside the self, such as work, friends, hobbies and social activities, may be withdrawn back into the self, leaving the patient uninterested, sullen, apathetic and selfconcerned. In this respect convalescence is like adolescence—a rechanneling of emotion and interest outward, into more mature investments.

Devaluation and Denial.—The anxiety is lessened by minimizing, devaluating or denying the reality of the anxiety-producing factors. It is a common observation that some persons can deny the existence of medical, economic or marital problems to the point of ultimate ruin. To deny or devaluate what one does not wish to believe may be solacing although hardly *mature.* (And certainly failure to follow the physician's instructions is often a subtle manifestation of the patient's reluctance to accept the existence of his organic disease.)

Postponement.—When it habitually forestalls or actually prevents constructive action, postponement is pathologic. A delightfully neurotic character was Dickens' Mr. Micawber, whose constant "waiting for something to turn up" dulled the edge of all life's reverses which action might have prevented.

Sublimation.—The normal emotional energy that becomes dammed up by frustration is diverted through sublimation into vicarious outlets, which are usually constructive or at least socially acceptable. Normal living demands this in moderation; asceticism requires it in extreme degree. But if the mechanism breaks down, outlets that are destructive to the person or to society may be utilized, and symptoms appear.

Projection.—To attribute one's own motives or defects to others is to project them. Carried to extreme, "all things look yellow to the jaundiced eye." Projection is the chief mechanism in paranoid reactions.

Introjection.—The opposite of projection, introjection provides the basis of hero worship and is prominent in the production of grief.

Rationalization.—"So convenient a thing it is to be a *reasonable creature,* since it enables one to find or make a reason for everything one has a mind to do," observed Benjamin Franklin in his "Autobiography." Like devaluation and denial, rationalization can serve as a *reality-defacing* mechanism. The almost indispensable "sour grapes" reaction allays some of the anxiety of frustration in the same way that fatalistic beliefs and superstitions, so common at the battlefront, relieve fear. Many of the neurotic patient's defenses are rationalizations—plausible excuses he has devised for himself to make reality seem a little more palatable.

Displacement.—Emotional attitudes readily become displaced—or overflow—from their true objects onto secondary objects, as in "taking it out on the other fellow." Often the secondary object is a *symbol* which may later give rise to reactions that appear quite inappropriate without some insight into their symbolic significance. ("Never speak of a rope in the house of a man who has been hanged.")

Conversion.—By means of conversion the anxiety may be so completely transformed into physical terms, such as hysterical paralysis or anesthesia, as to leave the patient apparently calm, placid and happy—"la belle indifférence."

Repression.—With time the unsavory emotional memories are gradually thrust beyond awareness into the subconscious; they are repressed. Recollections of the past, "the good old days," ultimately become the most pleasant ones. But that the unpleasant, repressed material is not actually lost is easily demonstrable: certain psychiatric technics capable of recovering these buried emotional patterns reveal that repressed material is cumulative; it remains essentially unaltered by the person's subsequent intellectual development, and it does exert dynamic influence in the production of mental disease.

THE SUBCONSCIOUS

Except in the acute traumatic neurosis, wherein the precipitating factors are recent, overwhelming and obvious, conflicts sufficient to produce real mental disturbance are generally not entirely accessible to the patient —he is not entirely conscious of them. Nor are they reasonable. Emotional in origin, they usually defy the simple intellectual approach of telling the patient to stop worrying or straighten things out. If the patient could do this he probably wouldn't be seeking help. The highly intelligent patient, who actually does know better, may be powerless to alter thinking that has become emotionally magnified and distorted, because a large share of that distortion takes place at a level of mental functioning below consciousness, in the so-called subconscious.

Present day psychiatry conceives of the subconscious as a sort of subterranean reservoir of the mind, which contains all of a person's instinctual drives and into which go all his life's experiences. There ideas are subject to no logical appraisal or control as are conscious ideas; they can operate independent of his intellectual maturity and his sense of values. Symbols, primitive in nature, are utilized freely, occasionally displaying themselves in dreams or symptoms. In the subconscious mind conflicts may be waged which usurp a portion of the subject's normal energy to hold them in check. And such mental mechanisms as projection, regression, evasion and sublimation—all originally protective—may lead to the unreasonable extremes of neurotic illness.

In his highly readable book, "The Human Mind," Dr. Karl Menninger[1] suggests the following analogy:

> Think of the mind as a theatre. Let the field of consciousness be represented by the stage. On it, from time to time, there come and go certain actors (ideas and desires), directed from the wings by a stage-manager (the censor . . .), who has derived his standards and experiences from training and example and precept and pictured ideal—from the lives and mouths of parents, teachers, early friends, and other early influences.
>
> All of the actors—and we infer that there are very many of them—want to act. They will get on to the stage, if possible. The stage-manager holds some of them off stage merely until the proper time for their appearance. They are suppressed *pro tem.*, and come or go as called. Others never get on the stage at all. They are poor actors, or unclothed and motley, or belong in another show, and so have no business clamouring for admission here. Most of them are not even in the wings (the *foreconscious*), but are outside the theatre, thrown out, perhaps, in the course of previous rehearsals and performances. They noisily demand to be let in, hoping to get on to the stage, but the confusion they create is not heard on the stage or in the audience. These actors, locked outside, are repressed ideas and desires.
>
> These, the repressed, and even the suppressed, actors may trick the stage-manager by disguising themselves in various costumes and masquerading as proper actors in the show. They are never wholly proper, and the keen eye may detect their real identity and trace their origin. But the average playgoer (the ordinary person) will think only that the play is here and there a bit shabby or clumsy or strange.

PSYCHOTHERAPY

The Aim of Psychotherapy.—Since neurotic symptoms are fundamentally regressive, irrational, protective substitutions for the real problems which produce them, the aim of psychotherapy is to help the patient back to reality. He must achieve a more mature method of dealing with reality rather than escaping into neurosis. Attempts to substitute the physician's methods, or those of a relative or creed or cult—a sort of mental antitoxin —leave him little lasting benefit. Ideally, the patient should be helped to find his own way, a way commensurate with his abilities and his standards, by relieving him of disabling emotional handicaps. He must relearn to use his inherent adaptive mechanisms in coping with reality if he is to gain an active rather than a passive immunity to his neurosis.

More than any other form of therapy, psychotherapy must be individualized. To be rational it must be based on an adequate understanding of the psychopathologic condition being treated. Various avenues of psychotherapy are available to the physician:

Supportive Psychotherapy.—The emotional cripple, like the orthopedic cripple, may need the support of a crutch before he is able to walk alone. This support is implicit in the physician's attitude, in the physical examination, in conservative reassurance, perhaps in the discreet use of sedatives as emergency measures or in the protection of the patient against mistakes due to his illness. While thorough physical studies are necessary to rule out organic disease and to reassure the patient, once the somatic status has been established such studies should not be reopened without real indication, for repeated examinations which throw suspicion on an organ serve to focalize the patient's anxiety and cater to his evasive desire to attribute symptoms to organic disease rather than to his own disordered thinking.

---

1. Menninger, K. A.: The Human Mind, ed. 3, New York, Alfred A. Knopf, Inc., 1945, p. 279.

Manipulative Psychotherapy.—Alterations of aspects of the patient's environment, including occupational therapy, hobbies, play, social activities, routine, work and vacations are universal but generally only palliative devices. Often there can be accomplished some alteration of the factor of secondary gain (the real or fancied gain the patient derives incidentally from his neurosis—not the primary reason for the neurosis as is the case in malingering). In a decision on the efficacy of a vacation the intrinsic factors of the illness should be weighed against the extrinsic (the situational and environmental). If the person carries his problems with him he is his own problem, and a rest cure, a withdrawal from normal routines, affords an opportunity for greater turning in of interests by the provision of more time and energy for self indulgence. Perhaps, as has been suggested, physicians should occasionally examine their motives for sending anxious patients on vacations.

Release of Malignant Tensions.—The release of malignant tensions is a basic psychotherapeutic tool, in that it deals with fundamental causes of neuroses. Memories of experiences in which strong emotional responses were evoked retain that emotion, be it pleasant or unpleasant. These are emotionally charged memories, which often contain more feeling than fact and are capable of producing profound disturbances in personality. When they are subsequently recalled the original emotional responses are again evoked and, under proper circumstances, deflated. Psychiatry calls this process *abreaction,* whereby harmful memory patterns are divested of their destructive emotional charges. As the fears, the feelings of guilt and the hostilities are thus reduced to the level of the actual things feared or regretted or hated, the patient is enabled to see the traumatic experiences for what they are and to exercise more mature judgment, perspective and intellect in adjusting to them. By then working through these heretofore indigestible emotional memories, the patient can become desensitized to them, much as the allergic patient is desensitized to his antigens. Abreaction and desensitization are the basis of therapy in narcosynthesis, the short cut in psychotherapy used so widely in World War II, in which both conscious and subconscious traumatic memories are recaptured and relived by the patient in the semiconscious state induced by the intravenous administration of "sodium amytal" N. N. R. or "pentothal sodium" N. N. R. More subtle forms of release of malignant tensions are commonly provided by diversions, such as competitive sports as outlets for aggressiveness, or social and economic conquests as outlets for fears and feelings of insecurity. But the release of these disturbing tensions by simple mental catharsis—a thorough ventilation of the basic problems—offers a direct and often dramatically effective method of alleviating anxiety in the neuroses.

Explanatory Psychotherapy.—Once the mechanisms of a neurosis have been ascertained, the judicious explanation of them provides the patient with some degree of insight into the nature and origins of his illness. The illumination and interpretation of his conflicts allows physical symptoms to be divorced from fears of organic disease and leaves him with a more nearly adequate understanding of his own mental processes. The mental mechanisms, the errors, the emotional tensions and the subjective distortions of reality can then be viewed objectively. Perhaps suggestion, direct or implied, may be utilized. But insight should be given cautiously and often sparingly, with the realization that it may become intolerable to the patient if it confronts him with facts which he may be unable to face. Explanatory therapy is most helpful when it acts to dispel the patient's false fears, to clarify symptoms that may be confusing to him, to define the real nature of his disorder and his own mental pitfalls and to direct his course toward recovery.

Like any form of treatment, psychotherapy does have potential toxicity, which must be recognized to be avoided. The experience of psychiatrists would suggest:

Don't argue. This encourages opposition. The patient has reasons for feeling as he does, probably emotional reasons which are not amenable to logic anyway.

Don't become punitive. When baffled in diagnosis or thwarted in treatment there is an understandable inclination to displace onto the patient one's reaction to his disease. On the other hand, don't become maudlin, identifying yourself too much with the patient and neglecting to wean him away from his neurosis.

Don't try to substitute your standards for his own. They probably wouldn't be acceptable to him—at least until he worked them out for himself. And to use oneself as a criterion, even if it is justifiable, is poor psychology.

Don't accept the responsibility of making major decisions for the patient (particularly as to marriage, divorce and business affairs). The only safe way is for him to defer such decisions until he has regained sufficient stability to make them for himself.

Don't allow the patient to unload his share of the responsibility for his recovery onto you. For the physician to accept this encourages dependence in the patient whose goal should be independence.

Rather:

Approach the neurotic patient with a manner that displays at least as much interest as your approach to his roentgenogram or electrocardiogram.

Give him the assurance that you want to help him, and encourage him to take the initiative with the realization that at least half the responsibility in the treatment is his.

Listen to him—attentively, sympathetically, noncritically, without ridicule or amusement; remember that his problems and symptoms are not absurd to him.

Sift and interpret, isolating what, on the basis of your understanding of mental illness, are the basic etiologic factors and mechanisms. Then:

Gradually guide the patient back to a more mature way of dealing with his problems. Show him the probable relationship between his symptoms and his maladjustments and lead him out of his neurotic escape toward reality.

PROGNOSIS

Some generalizations as to prognosis in organic disease are often applicable to mental illness. The duration of the neurosis may determine the ultimate results of treatment; the more long standing the symptom pattern, the more fixed it becomes and the more deep rooted and numerous the secondary changes likely to take place in the personality. These may eventually render the original disorder inaccessible, if not obscure. Also, the amount of stress necessary to produce the disorder—whether it was cumulative or acute stress—is often a rough measure of the treatment necessary to restore equilibrium. Particularly, the patient's personality assets are of prognostic significance, including his intelligence, his emotional maturity and especially his inherent stability as judged by his previous performance and achievements. The person who has been able to achieve adequate social, occupational and marital adjustments in the past logically can be expected to have a far better prognosis than the one who has lived on the ragged edge of security in constant conflict with his environment.

Obviously, many neurotic patients cannot be cured. For some of them the secondary gains of illness are too great or reality is too severe. But even these patients can be helped to cooperate with the inevitable—to live with their illness, as the diabetic patient is taught to live with his. By helping psychoneurotic patients to achieve a more satisfactory adjustment to themselves and to reality, the physician enables them to live lives which are healthier both mentally and physically.

EPIDERMAL CARCINOGENESIS

E. V. COWDRY, Ph.D.
St. Louis

About ten years ago I was invited to initiate a long term cancer project at Barnard Hospital. It was decided to study development of cancer in the most favorable experimental conditions that could be found.

Epidermis was chosen as the tissue chiefly because it makes up the surface of the body and is easily accessible. But we had in mind also other advantages. It provides cells of a single type conveniently arranged in layers of increasing differentiation with a minimum of intercellular material and no blood vessels. Because of its avascularity and high degree of cellularity, chemical analyses relate more directly to the epidermal cells than do those of any other tissue.

Mice of a closely inbred strain were selected as the animals in order to reduce individual variability to a minimum.

Methylcholanthrene was selected as the carcinogen because substances of somewhat similar nature naturally occur in the body and it can be obtained in a chemically pure state, making possible standardization of dosage. Methylcholanthrene was applied to the skin in a 0.6 per cent solution in benzene.

We had then a biologic equation for analysis:

Epidermis + Carcinogen Repeatedly Applied → Hyperplastic Precancerous Epidermis — Carcinogen → Squamous Cell Cancer.

The method has been to determine quantitatively the properties of normal untreated epidermis, of epidermis in various stages of hyperplasia and of the resulting cancers.

In the accompanying table, passing from left to right, the properties are listed, the changes from the normal found in precancerous hyperplastic epidermis are given and likewise the changes from the precancerous epidermis discovered in the cancers, and lastly references are supplied to the papers by members of our team reporting the findings.

I. PRECANCEROUS HYPERPLASIA

Before any cells display malignant behavior in the response to cutaneous applications of carcinogen, the epidermis becomes hyperplastic. It also becomes precancerous in the sense that conditions are established in it which antedate the development of cancer. This precancerous period lasts for ten or more weeks—a long time in the life of a mouse.

Some changes in the properties of precancerous hyperplastic epidermis from those of normal untreated epidermis have been determined. Space permits listing only the direction of the change, whether it is an increase or a decrease, and its extent figured as a percentage of the normal. In general, the percentage changes are attained promptly. Since they endure without substantial modification for weeks, the new conditions and the properties in which no changes are noted constitute together a new precancerous epidermal equilibrium.

Examination of data in column I of the appended "Balance Sheet," therefore, provides clues as to the condition of cell life in the epidermis, which, for a considerable time, are imposed on many epidermal cells before a small minority of them show evidence by their behavior of having undergone a malignant transformation. Multiple chemical deficiencies appear to predominate. Note especially the decreases in total lipid, calcium, iron and biotin. Except for a substantial and late increase in cytochrome oxidase activity, the increases in properties are mild compared with these deficiencies. There are, for instance, slightly more magnesium, pyridoxine and water. But the importance of the extent of change in any property, whether an increase or a decrease, can be overestimated. Those measured in but small percentages may be as significant as the larger ones. The mind quickly gets to work trying to put 2 and 2 together in an attempt logically to construct a picture of the consequences of these changes. We withhold judgment because the unexpected so often happens in our studies. The further we go the more involved our task becomes.

However, it is safe to say that the conditions of cell life of the cellular population as a whole have been fundamentally changed. The cells must face deprivations and hardships to which epidermal cells are not normally subjected. As is to be anticipated in making the necessary adjustments, the cells change. They swell and become larger both in cytoplasmic and nuclear volume, but the nucleocytoplasmic ratio declines. Cell division is speeded up in frequency and the nuclei show distinctive changes—decrease in thymonucleic acid, increase in displaceability of chromatin and nucleoli and abnormal mitoses. In the chromosomes themselves, there is a decrease in desoxyribonucleic acid.

The principal handicap seems to be felt more by the spinous cells than by the basal ones. Their increase in size is greater and the displaceability of their nuclear contents subjected to ultracentrifugal force is more marked. Demineralization, revealed by the microincineration technic, is often greater in the intermediate epidermal zone occupied by spinous cells than in the more distal and more proximal zones. This may signify that the spinous cells suffer more from calcium (the chief component of the predominant white ash), and perhaps from other deficiencies, than do the basal cells nearer the source of supply in the underlying dermis. The normal epidermis of the backs of mice is so thin that a clearcut distinction between spinous and basal cells does not obtain, but in the normally thick epidermis of their foot pads this distinction is marked, and mitotic frequency is greatest in the spinous cells. We attach some significance to the fact that in precancerous hyperplastic epidermis maximum mitotic frequency is in the basal layer. It is as if conditions

Balance Sheet: Integration of Changes in Experimental Methylcholanthrene Epidermal Carcinogenesis

Properties	I Precancerous Hyperplasia Changes from Normal Epidermis	II Cancer, Changes from Precancerous Hyperplasia	Workers
Cell volume	Over 300% increase in spinous cells; about 225% increase in basal cells	Usually decrease in 17 cancers compared with hyperplastic spinous cells	Cowdry, E. V., and Paletta, F. X.: J. Nat. Cancer Inst. **1**: 745-759, 1941
Nuclear volume measured in sections	About 100% increase in spinous cells; about 75% increase in basal cells	Usually increase in 17 cancers compared with hyperplastic spinous cells	
Nuclear volume measure of whole nuclei separated by centrifugation	50% increase including those of all epidermal cells	Not measured	Kraemer, D. Z.: Anat. Rec. **94**: 289-311, 1946
Nucleocytoplasmic ratio	30-40% decrease in spinous cells; about 60% decrease in basal cells	Not measured	Cowdry, E. V., and Paletta, F. X.: Am. J. Path. **17**: 335-358, 1941
Displaceability of chromatin and nucleoli by ultracentrifugal force	Gradual increase, mostly in spinous cells	Marked increase uniformly in malignant cells; no accurate quantitative data	
Intranuclear thymonucleic acid (Feulgen reaction)	Decrease	Increase but less than in normal epidermis	Stowell, R. E.: J. Nat. Cancer Inst. **3**: 111-121, 1942
Mitotic frequency in mounts of whole epidermis	Increase about 1,000%	Cannot be counted in whole mounts because of thickness	Cooper, Z. K., and Reller, H. C.: J. Nat. Cancer Inst. **2**: 335-344, 1942. Reller, H. C., and Cooper, Z. K.: Cancer Research **4**: 236-240, 1944
Mitotic frequency in sections of epidermis	Maximum shifts to basal layer from normal location in thick epidermis in spinous layer	Distribution in layers not feasible to measure in cancers	Cowdry, E. V.: Van Dyke, J. H., and Geren, B. B.: Cancer Research **6**: 620-624, 1946
Abnormal mitosis	Appears at 2 days; percentage of abnormal metaphases less than 40	Increase in number; percentage of abnormal metaphases greater than 50	Biesele, J. J., and Cowdry, E. V.: J. Nat. Cancer Inst. **4**: 373-384, 1944
Cytoplasmic ribonucleic acid	Initial increase	High in one cancer studied	Biesele, J. J.: Cancer Research **4**: 737-750, 1944
Alkaline phosphatase	Initial increase chiefly in basal cells	No change in spinous but slight increase in basal cells	Biesele, J. J., and Biesele, M. M.: Cancer Research **4**: 751-755, 1944
Mineral residue from microincineration	Patchy demineralization; spinous layer especially	(Method requires improvement)	Paletta, F. X.; Cowdry, E. V., and Lischer, C. E.: Cancer Research **1**: 942-952, 1941
Total lipid/P N* ratio	60% decrease	Determinations not made yet	Wicks, L. F., and Suntzeff, V.: J. Nat. Cancer Inst. **3**: 221-224, 1942
Cholesterol/P N ratio	45% decrease	Determinations not made yet	Wicks, L. F., and Suntzeff, V.: Cancer Research **5**: 464-468, 1945
Lipid phosphorus/dry weight ratio	30% decrease	91% increase	Costello, C. J.; Carruthers, C.; Kamen, M., and Simoes, R. L.: Cancer Research, to be published
Specific activity of P 32 in phospholipid fraction	No change	No change	
K/N P ratio	No change	16% decrease	Carruthers, C., and Suntzeff, V.: Cancer Research **3**: 744-748, 1943; Suntzeff, V., and Carruthers, C.: J. Biol. Chem. **153**: 521-527, 1944
Na/N P ratio	No change	22% decrease	Carruthers, C., and Suntzeff, V.: Cancer Research **3**: 744-748, 1943
Mg/N P ratio	25% increase	17% decrease	Carruthers, C., and Suntzeff, V.: Cancer Research **3**: 744-748, 1943; Suntzeff, V., and Carruthers, C.: J. Biol. Chem. **153**: 521-527, 1944
Ca/N P ratio	60% decrease	53% decrease	Suntzeff, V., and Carruthers, C.: J. Biol. Chem. **153**: 521-527, 1944
Ratio of free to bound Ca	No change	Decrease free Ca	Lansing, A. I.: to be published
Fe/N P ratio	Decrease, 50% early, 70% late	No measured change; actually slight decrease because of Fe in hemoglobin	Carruthers, C., and Suntzeff, V.: J. Nat. Cancer Inst. **3**: 217-220, 1942; Science **99**: 245-247, 1944
Cu/N P ratio	10% decrease	70% decrease	Carruthers, C., and Suntzeff, V.: Science **99**: 245-247, 1944; J. Biol. Chem. **159**: 647-651, 1945; Cancer Research **6**: 296-297, 1946; ibid, **6**: 8-10, 1946
Zn/N P ratio	30% decrease	55% decrease	
Ascorbic acid/N P ratio	No change	No change	Carruthers, C., and Suntzeff, V.: J. Nat. Cancer Ins. **3**: 217-220, 1942
Bioassays of p-aminobenzoic acid by means of mutant strains of Neurospora	No change	28% increase	Tatum, E. L.; Ritchey, M. G.; Cowdry, E. V., and Wicks, L. F.: J. Biol. Chem. **163**: 675-682, 1946; Ritchey, M. G.; Wicks, L. F., and Tatum, E. L.: J. Biol. Chem., to be published
Choline	Slight increase	133% increase	
Inositol	Slight increase	119% increase	
Pyridoxine	24% increase	25% increase	
Biotin	61% decrease	19% increase	
Succinic dehydrogenase activity	No change	350-450% increase	Carruthers, C., and Suntzeff, V.: Cancer Research **7**: 9-14, 1947
Cytochrome oxidase activity	Slight increase early, 100% increase later	12% decrease	
Water content	10% increase	23% increase	Carruthers, C., and Suntzeff, V.: Cancer Research **6**: 296-297, 1946; ibid. **6**: 8-10, 1946
Desoxyribonucleic acid on wet weight basis	36-40% decrease like nucleocytoplasmic ratio	38% decrease	
Desoxyribonucleic acid in chromosome masses collected by ultracentrifugation	23% decrease	110% increase	Gopal-Ayengar, A. R., and Cowdry, E. V.: Cancer Research **7**: 1-8, 1947

* Protein-nitrogen. † Nucleoprotein-phosphorus.

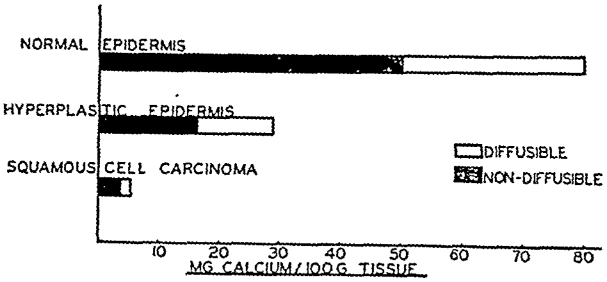
for cell division were unfavorable in the spinous layer as compared with the better located basal layer. Moreover, in the spinous cells, abnormal mitoses are more conspicuous than in the basal ones.

Purely as a working hypothesis, we entertain the idea that the malignant change is a mutation in a small number among the legion of spinous cells subjected to the brunt of the deprivations. In terms of Spencer's theory, it is a rare event in a struggle for existence, which, in this case, has gone on for a long time.

II. CANCER

Coming to the actual cancers, I have indicated briefly, in column II of the table, the properties as compared with those of the preceding precancerous epidermal hyperplasias. Prior to 1944, we worked with numerous individual cancers chiefly by microscopic methods. Later on, we made many analyses of pooled transplants of a single cancer, each transplant so small that necrotic tissue was at a minimum. In these, the outlines of another chemical equilibrium are beginning to take shape.

Examination of column II of the table shows that in cancer also there are conspicuous chemical deficiencies. The decreases are not percentages of the properties of normal epidermis but of the properties of precancerous hyperplastic epidermis (column I of the table). The continued decline in calcium, copper and zinc is precipitate. Of the total calcium, less is the free form. The decrease in cytochrome oxidase activity is intriguing in comparison with the 100 per cent increase over normal in precancerous hyperplasia. But, on the whole, increases are more numerous than deficiencies. The largest increases in percentages are in lipid phosphorus, choline, inositol and succinic dehydrogenase activity. The increase in desoxyribonucleic acid in isolated chromosomes, compared with the decrease in the whole tumor, is interesting. Other moderate increases are in water content and in various B vitamins. As yet we are in no position to try to discern a pattern in these changes; yet it is clear that a second and different chemical equilibrium exists in the cancers and that the behavior of the cells is profoundly modified.



Differences in amounts and proportions of diffusible and nondiffusible calcium in normal epidermis, hyperplastic epidermis and squamous cell carcinoma.

Obviously, many questions remain to be answered, and some apparent inconsistencies require explanation. Even the contrast made between the data in columns I and II of the table may lead us astray. The chemical determinations are of whole precancerous epidermis of the area treated, usually of pooled specimens from several mice to give adequate quantity. The range of variation as between treated mice, and in different parts of the hyperplastic epidermis of a single mouse, is not known. It may be that the new chemical equilibrium is not evenly spread throughout the entire epidermal cell population analyzed. The deviations from normal in column I of the "Balance Sheet" actually may be greater in some areas (perhaps in the intermediate spinous zone) than the figures indicate, being reduced in the whole tissue by the inclusion of areas less changed.

In the same way, the new equilibrium found in the cancers may not be restricted to them, but may antedate the actual cancers. It may exist in small areas of precancerous epidermal hyperplasia in which it is not revealed by our analyses of many pooled specimens, being hidden by the large amount of epidermal tissue not similarly altered included in the analyses. Thus the hyperplastic epidermis may not be precancerous in the sense that I have defined it. On the contrary, it may include some cells which have undergone the malignant transformation and do not display it, because they are still immobilized within the epidermis.

Despite these qualifications it is clear that our analysis of the biologic equation proceeds at four levels: (1) the fact-finding investigation of the properties of precancerous epidermis (column I of the table); (2) experiments based on these facts designed to modify the chemical equilibrium of precancerous epidermis in the direction of normality and thus to prevent development of cancer; (3) the fact-finding investigation of the properties of the resulting cancers (column II), and (4) experiments based on these facts designed to modify the chemical equilibrium of the cancers in the direction of normality and thus to cure them, or, after discovering their specific vulnerability, to devise means of killing them.

The experiments on the second and fourth levels have hardly been started. The same may be said for parallel studies of human tissues on all four levels employing the methods proved useful for mice. But our work is not too rigidly stratified. Some general ideas begin to emerge:

1. Simpson and Cramer[1] (1943) traced the carcinogen into the skin by its fluorescence. They found that methylcholanthrene soon disappears and that three other fluorescent materials appear. It is possible therefore that in this situation methylcholanthrene itself is not the actual carcinogen. Our idea is that what we glibly call carcinogens may be materials which themselves do not generate cancer but which set in train a sequence of events which in certain circumstances does. In man the sequence is usually broken. Were it not so incidence of cancer would be much greater.

2. The same two members of the team[2] (1944) tried the effect of offering methylcholanthrene to the epidermis in a more natural vehicle than benzene, namely, wool fat. They were surprised to find that no cancers resulted. After a long interval they treated the same mice with methylcholanthrene in benzene, and cancers sprouted in a higher percentage and more quickly than in mice not previously treated with the methylcholanthrene in wool fat. Evidently the methylcholanthrene in wool fat sensitized the epidermis to a subsequent application of the same carcinogen in benzene.

Further experiments revealed that this hypersensitivity was not restricted to the carcinogenic influence of methylcholanthrene but applied to the carcinogenic influence of burns. In mice whose skins were not sensitized in this way cancers developed at the sites of burns only extremely rarely, whereas in those made hypersensitive cancers developed rather frequently. All this Simpson reported [3] at the recent meeting of the American Association for Cancer Research in Chicago. It means that one must also consider the possibility of induced hypersensitivity to carcinogens in man, and further that this hypersensitivity may not be single but multiple. Thus is the complexity of cancer etiology increased.

[2] Simpson, W. L., and Cramer, W.: Sensitization of Skin by Carcinogenically Inactive Methylcholanthrene to Subsequent Carcinogenesis. *Cancer Research* 5: 5-10, 1944.

The possible factor of hypersensitivity is additional to the factor of local tissue deficiency so evident in mouse epidermis. It is interesting that the deficiency in our series is, like the hypersensitivity, multiple, involving other essential substances besides calcium. In the later years in man, when incidence of cancer is high, local tissue deficiencies may be prevalent. Thus far but little search has been made for them.

3. The observations on calcium deficiency already seem susceptible of partial interpretation. They are as follows:

Calcium, Milligrams per Hundred Milligrams of Tissue

	Normal mouse epidermis 0.014	Normal old mouse epidermis 0.034
Embryo mouse epidermis 0.016	Normal human epidermis 0.016	Precancerous mouse epidermis 0.019
	Cancer, human 0.008	Cancer, mouse 0.009

Note especially that the concentration of calucium in human epidermis is almost the same as in mouse precancerous epidermis and in human and mouse squamous cell cancers.

The change in proportions of free to bound calcium in our experimental series reported by Lansing and Au [4] at the same meeting in Chicago is dramatic.

Not only is the total epidermal calcium decreased in carcinogenesis but the amount of free diffusible calcium becomes much less. It is known that in other tissues decrease in free calcium loosens the intercellular material so that the cells fall apart. Perhaps the anchorage of the epidermal cells in the precancerous epidermis fails with decrease in free calcium which may occur in the tiny area of beginning invasion and not be reflected in the determinations of whole precancerous epidermis. At any rate the invasiveness of growing cancers may be correlated with the undoubted increase in the proportion of free or diffusible calcium to bound calcium and the decrease in total calcium.

Simpson and Gopal [5] reported at the same Chicago meeting the results of experiments with hyaluronidase. Briefly stated, this enzyme greatly facilitates the spread of our experimental cancers. When it is injected in their vicinity they metastasize far more than in its absence. Therefore, in addition to the breaking down of the cohesiveness of cells by the calcium deficiency, there is a spreading factor that increases the permeability of the ground substance of connective tissue. The idea has some justification that to prevent spread decrease in calcium content of epidermis must be corrected and antihyaluronidase must be supplied to counteract the hyaluronidase.

SUMMARY

In conclusion, therefore, our experiments at Barnard Hospital and in Washington University indicate the possibility that multiple deficiencies in the content of essential components of epidermis make the conditions of cell life therein difficult, predisposing to mutations having survival value. Some of these mutations may constitute the malignant transformation. Hypersensitivity to the carcinogen and also to burns can be induced. The decrease in epidermal calcium may favor the breaking away and initial invasion of the dermis by malignant cells. Further spread of cancer is increased by hyaluronidase and may possibly be inhibited by antihyaluronidase, but of the latter we as yet have no evidence.

ABSTRACT OF DISCUSSION

DR. R. R. SPENCER, Washington, D. C.: Basically this project, as I see it, is a study of the carcinogenic mechanism or the transformation that takes place from the precancerous to the cancerous condition, structurally, functionally and chemically. I think that Dr. Cowdry chose the skin because of its accessibility, and you have seen the interesting results obtained. What the sum total of these results means at present I do not know. It would be extremely interesting if some other tissue by some other group were to be studied in this way. I would doubt very much if you would find the identical chemical, structural and morphologic changes in some other organ. I think, too, that in this project, which has been going on several years—and it takes a long time to get these results—he has shown a good example of what is termed "interdisciplinary research" or at least the necessity for interdisciplinary research in cancer, because among Cowdry's group he has physicists, chemists, morphologists and pathologists. It is necessary nowadays to "gang up" on the cancer problem. Otherwise we will not get very far. I have always felt that from now on the great discoveries in cancer will come from group efforts of this type. I have nothing but praise for this pioneering work of Dr. Cowdry.

DR. M. J. SHEAR, Washington, D. C.: For years in the Public Health Service we had been studying the effect of hydrocarbon carcinogens mainly in the subcutaneous tissues of the mouse. Among the findings made with the collaboration of Mr. Leiter was this: that when lard was used as the vehicle for benzpyrene (we restricted it to benzpyrene in this particular set of one hundred and eight experiments with 5,000 mice), following the work of Kennaway and his associates in London, it was found that variable results were gotten with different batches of lard. When that was tracked down by chemical fractionation of the lard, one fraction of lard came out which we termed fraction IV, which exercised a restraining effect on the induction of sarcomas. Whereas sarcomas were produced in 30 or 35 out of fifty control mice, when the same amount of benzpyrene was dissolved in fraction IV and injected into the same strain of mice we got only 2 sarcomas out of 50. That finding was made repeatedly. Here we have from the Barnard Free Skin and Cancer Hospital another carcinogen (methylcholanthrene), another tissue (the skin) of the mouse and another lipid (wool fat); yet similar inhibition of tumor genesis was observed. I should like to mention that another group of investigators at the McArdle Laboratory at Wisconsin, under Dr. Rusch, has made another finding which fits in. They used still another carcinogen, which when given orally produces tumors of the liver. They were studying the effects of different diets and dietary components and, curiously enough, when in the diet there was incorporated hydrogenated coconut oil with the carcinogen they got repression of the induction of tumors of the liver. These three substances —our fraction IV of lard, wool fat at Barnard Free Skin and Cancer Hospital and hydrogenated coconut oil at Wisconsin—all have certain chemical properties in common. It seems worth further study to see whether this phenomenon has still wider applicability, and whether on oral administration of certain hydrogenated fatty materials it would be possible to repress the induction of other tumors and possibly of spontaneous tumors. I should also like to add to what Dr. Cowdry said about this type of systematic work offering suggestions for leads in attempts at chemotherapy. For upwards of forty years it had been alleged on the basis of scanty data that administration of calcium would help control tumor growth. It has been found by us and by others that administration of simple calcium-containing materials was without noticeable effect. But in view of the striking finding made in St. Louis that there is a sharp decrease in the calcium content of malignant cutaneous tumors as contracted with normal skin, less obvious approaches in attempts to increase the calcium content of malignant cells may yield interesting results.

[5] Gopal-Ayengar, A. R., and Simpson, W. L.: Hyaluronidase and the Growth of Malignant Epithelial Tumors, paper read before the American Association for Cancer Research, Chicago, April 17, 1947.

Dr. Cowdry, St. Louis: I am glad that Drs. Spencer and Shear brought out those points which they did about my paper because we want you to understand that this is an integrated program, one in which we are trying to find out the facts now, and we are going to attempt to prevent and cure just as soon as possible on the basis of the facts. We think—and I may be a little visionary—that there is a possibility that multiple deficiencies are factors in making the conditions of cell life so arduous that mutations result. We are thinking along lines that I believe Dr. Spencer was thinking along when he delivered his pioneer lecture some years ago, that it is of a survival mechanism. It is not necessary that these deficiencies be the same or these hardships be the same. They may produce mutations. We think that not only may there be local deficiencies promoting mutations but also hypersensitivities which are likewise local, and we are concerned very much with the third point of the breaking loose of the malignant cells and of their invasion or perhaps of their restraint. You see, this leads directly into the problem of hyaluronidase. We have the strong feeling that the Russian ACS (antireticular cytotoxic serum) probably contains some antihyaluronidase and that this explains its sometimes very interesting results.

Acetylcholine and Cholinesterase.—Neostigmine and physostigmine act in the same way. Both depend on the presence of acetylcholine. According to Loewi, Dale and Nachmansohn, there is strong evidence that, in the nervous system, transmission of the impulse from one neurone to the next depends on a formation of acetylcholine at the synapse. This chemical transmits the impulse to the next neurone, and, at the end of the chain, to the ganglion cell in smooth muscle or to the end plate in striated (voluntary) muscle. There is present at these points cholinesterase, which immediately destroys the acetylcholine and allows the synapse or motor end plate to rest until the next stimulus arrives. This process occurs throughout the entire central and peripheral nervous system except in the postganglionic sympathetic nerves, which have their own chemical mediator, sympathin.

The pharmacologic effect of neostigmine and its natural analogue, physostigmine or eserine, is that of depressing the amount of cholinesterase present in the serum. In other words, neostigmine, by depressing the esterase, strengthens the action of acetylcholine on the effector organs. This effect, in the postganglionic fibers going to smooth muscle, is similar to the action of a drug called muscarine and is called "the muscarine effect." The effect on the nerve endings in striated (voluntary) muscle is similar to the early action of nicotine and is called "the nicotinic effect of the neostigmine." The postganglionic nerves going to smooth muscle, and the motor nerves going to striated muscle, are called cholinergic nerves. It is important to note, however, that the nerve supply from the central nervous system to the sympathetic ganglia is also mediated by acetylcholine and (its constituents) are, therefore, cholinergic nerves.—Schwab, R. S., and Chapman, W. P.: Clinical Uses of Neostigmine, *The Medical Clinics of North America*, September 1947.

IMPROVEMENT OF RESULTS IN THE TREATMENT OF UTERINE CANCER

J. HEYMAN, M.D.
Stockholm, Sweden

For the time being there are but two ways in which to control cancer: surgical intervention and radiotherapy. As far as uterine cancer is concerned the surgical technic has been brought to perfection, and further development is hardly to be expected. Thus, significant improvement of the results in treatment of uterine cancer is synonymous with improvement in radiotherapy.

The idea of this paper is to show that—according to the Radiumhemmet experience—it is possible to improve the radiotherapeutic results in cancer of the corpus as well as in cancer of the cervix and to report on various procedures which my colleagues and I have adopted for that purpose.

CANCER OF THE CORPUS

For the last five years about 85 cases of corpus cancer have been referred annually to the Radiumhemmet for radiotherapeutic treatment. About half these cases are not suitable for surgical treatment either because of the spread of the growth (10 to 15 per cent of the total) or because of old age, adiposity, cardiac conditions, diabetes and similar complicating diseases (40 to 42 per cent of the total). In addition, the number of clinically operable cases referred to the clinic by the specialists for radiotherapeutic treatment is increasing year by year. At the Radiumhemmet it has thus become an important problem to develop a satisfactory radiotherapeutic technic for the treatment of corpus cancer.

Table 1.—*Cancer of the Uterine Corpus at the Radiumhemmet*

Five year result in patients treated 1914 to 1941 inclusive

Total number of patients examined	842
Alive without evidence of the disease	442
Absolute cure rate	52.5%

Since 1933 we have adopted a combined operative and radiotherapeutic treatment in which radiotherapy plays the primary and most important part. Surgery is used only in case of failure of radiotherapy. The radiotherapeutic technic which we now use in all cases of cancer of the corpus is called the packing method. The uterus is packed with a sufficient number of uniform radium containers to completely fill the cavity. The technic was recently described in detail in the *British Journal of Radiology*.[1] The necessary variations in the treatment times, given by the physical department in tabular form, are published in the *Acta Radiologica*.[2]

During the period 1914 to 1941 inclusive 842 patients suffering from cancer of the corpus have been examined at the Radiumhemmet gynecologic clinic with a view to treatment. Table 1 shows the result estimated after a period of five years from the beginning of the treatment.

Address of the invited foreign guest read before the Section on Obstetrics and Gynecology at the Ninety-Sixth Annual Session of the American Medical Association, Atlantic City, N. J., June 13, 1947.

[1] Heyman, J.: Brit. J. Radiol. **20**: 85-91, 1947.

[2] Heyman, J.; Reuterwall, O., and Benner, S.: Acta radiol. **22**: 14-98, 1941. Heyman, J., and Benner, S.: ibid. **27**: 328-333, 1946.

With regard to the stated result the following should be observed. This becomes apparent when the following facts are considered. The series does not represent selected cases. The Radiumhemmet serves the northern and middle part of Sweden, and all patients with cancer who are referred for radiotherapy are dealt with there. No matter how advanced the disease may be, the case must be accepted and must appear in the records. In 29 of the foregoing 842 cases treatment was considered unsuitable principally because of the extent of the disease.

In all cases the cancer is microscopically verified. However, the series does include 55 debatable cases. According to our chief pathologist these 55 are most probably adenocarcinomas, though infiltrative growth cannot be definitely demonstrated. Fifty-five of the 442 patients reported as alive and free from evidence of the disease have been operated on after failure of radiotherapy.

The introduction, about 1933, of the packing method has brought about a definite improvement in the results obtained (table 2).

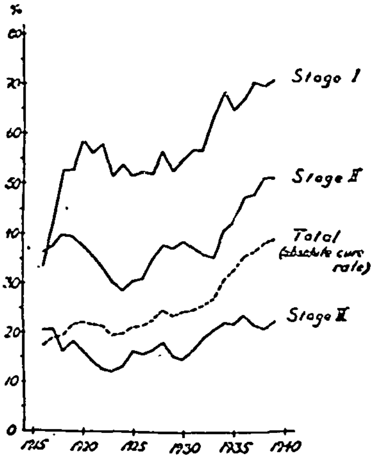

Fig. 1.—Five year result in treatment of cancer of the uterine cervix at the Radiumhemmet, Stockholm, 1914 to 1941 inclusive.

In the period 1914 to 1933 the relative cure rate is 44.6 per cent; in the period 1934 to 1941 inclusive it is 61.9 per cent. The two series are comparable because there is only an insignificant difference in the quality of the clinical material. Further, the proportion of cases with operative intervention and the number of microscopically debatable cases are less in the latter period.

Consequently the improved result must be credited to an improvement of the radiotherapeutic technic.

In cancer of the corpus the result obtained with the packing method (plus operation in case of failure) is considerably superior to that obtained by surgical means alone. It seems to compare favorably with the result obtained by primary hysterectomy plus postoperative irradiation, as far as published results justify such a comparison. By primary radiotherapy equal or better results will be obtained with less risk and less inconvenience to the patients. To me it is obvious that the use of primary surgical intervention in cancer of the corpus will gradually be substituted by primary radiotherapy.

CANCER OF THE CERVIX

In the thirty-four years during which I have served as senior gynecologist to the Radiumhemmet 6,200 patients with cancer of the cervix have been examined there with a view to treatment. Most of them I have examined, classified, treated and followed personally. All patients are traced. No precancerous conditions are included.

Table 2.—*Five Year Result of Treatment of Cancer of the Uterine Corpus in Different Periods*

	1914-1933	1934-1941
Total number of patients treated	354	459
Alive without evidence of the disease after a period of observation of 5 years	158	284
Relative cure rate	44.6%	61.9%

In 4,611 cases a period of at least five years has elapsed since the beginning of treatment. Figure 1 demonstrates the five year cure rates obtained in this series of cases.

The dotted line represents the absolute cure rate, that is, the proportion of patients alive and free from evidence of the disease expressed as a percentage of the total number examined with a view to treatment, whether they are treated or not. The stage rate is the proportion of cured patients expressed as a percentage of the total number in that stage actually treated.

A considerable improvement of the result is noticeable since 1932. It is less obvious in stage 3 because of the relatively high cure rate in the beginning of the period. This is partly due to the small number of cases, partly to the fact that the classification system recommended by the League of Nations' Committee had not yet been adopted.

Table 3 shows the difference between the cure rates prior to and after 1932 expressed in figures.

In the following paragraphs I will try to explain the reasons for the improvement of the results in the last fifteen years.

The improvement is not temporary; it has been noticeable for fifteen years, and consequently it is permanent. Because of the size of the samples it cannot be due to chance variations. It cannot be explained by variations in the quality of the clinical material; since 1923 there have been no such variations of any significance. Further, it cannot depend on an alteration of the routine method of brachyradium treatment. At the Radiumhemmet the Stockholm method is still used; it has been modified only slightly since its adoption in 1914. Finally, there is no differ-

Table 3.—*Difference in the Cure Rates of Cancer of the Uterine Cervix*

	Five Year Result of Treatment		
	1914 to 1931 Incl.	1932 to 1941 Incl.	Difference
Absolute cure rate	21.6%	34.9%	13.3%
Relative cure rates:			
Stage 1	52.4%	69.3%	16.9%
Stage 2	34.7%	46.5%	11.8%
Stage 3	15.6%	22.1%	6.5%

ence in the use of additional roentgen ray and teleradium irradiation sufficiently pronounced to explain the improvement. There is, as far as I can see, only one acceptable interpretation: the improved results are due to a superior judgment in handling the individual case, which, in turn, originates from an increased experience.

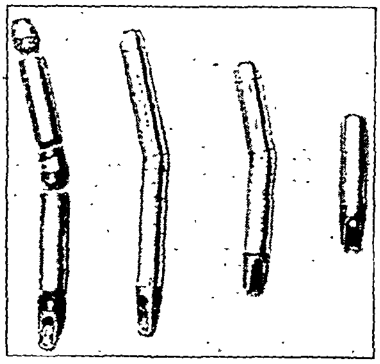

Fig. 2.—Intrauterine applicators.

The original Stockholm method (fig. 3) in treatment of cancer of the cervix consists of a coincident intrauterine and vaginal application of radium salt, screened by a filter equivalent to 3 mm. of lead. The intrauterine applicator (fig. 2) usually holds 50 to 60 mg. element of radium, its length corresponding to that of the uterine canal. For vaginal application the tubes are placed in cylinders (fig. 4) or flat applicators (fig. 5), which vary considerably in size. The applicator chosen in the individual treatment should be sufficiently large to cover the entire surface of the tumor and to distend the vagina laterally. They contain as a rule 80 to 100 mg. of radium. Gauze packing provides the necessary distance between the vaginal applicator and the rectum and keeps the vaginal applicators in position (fig. 5 *A*).

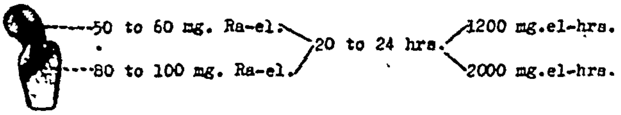

Fig. 3.—Brachyradium treatment of cervical cancer according to the Stockholm method.

Two treatments are given, each lasting for about twenty to twenty-four hours, with an interval of three weeks. In the two treatments the total intrauterine dose is 2,400 to 2,600 mg. hours and the total vaginal dose 4,000 mg. hours.

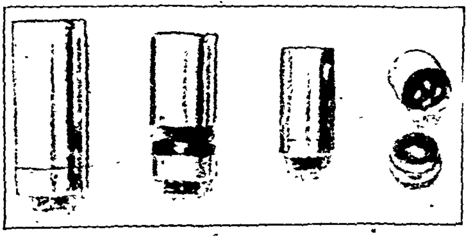

Fig. 4.—Cylinders for vaginal application.

Supplementary roentgen radiation to the parametrium is used as a routine measure. Its value is difficult to estimate even in advanced cases.

Time does not allow me to report on the variations in the standard technic which have been adopted in recent years. The variations are mainly characterized by a 25 per cent increase of the intrauterine dose and a 10 per cent decrease of the vaginal dose.

Correct application of the Stockholm method requires considerable variation in the individual case. The vaginal applicators must be chosen with regard to both shape and extent of the growth. Variations in the vaginal dose are necessary with regard to the size and shape of the applicators chosen, the width of the vagina, the age of the patient and a number of other factors.

The treatment is not varied according to the histologic character of the tumors. No practical difference has been observed by us in the results obtained in the treatment of various histologic types of growth.

The mentioned variations in the standard technic have been practiced at the Radiumhemmet for about thirty years. Though of importance to the result of treatment they are not to be credited for the improvement of the result in later years. Far more important in that respect is the individualization of treatment in cases in which the standard technic would involve serious risks, i. e. those in which there is danger of the development of serious infection, salpingitis, pelvic peritonitis, general peritonitis or septicemia.

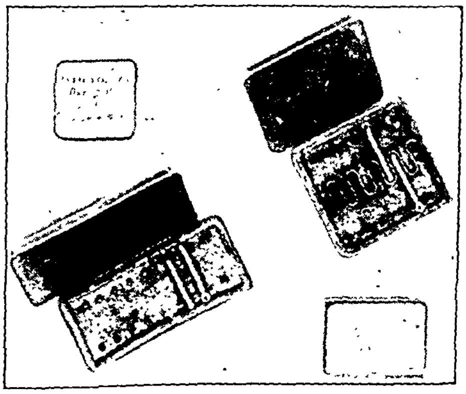

Fig. 5.—Flat vaginal applicators.

In all such cases the standard technic is abandoned or modified. Instead of the combined intrauterine and vaginal application a tentative treatment is given either as an intrauterine application if the cervical canal is easily accessible or else as a vaginal application. In order to diminish the risk of infection the amount of radium applied is increased and the treatment time correspondingly reduced. In many cases special instruments are used; for intrauterine treatment a large applicator which holds up to seven tubes each containing 50 mg. of radium (fig. 7) and for vaginal application a microbomb of two different designs one holding four 50 mg. tubes and the other up to seven such tubes (fig. 8). A tentative treatment time may if necessary be reduced to a couple of hours or less.

During the tentative treatment the patient is carefully watched and the temperature reading taken at least every other hour. Should the temperature rise the treatment is interrupted and will be repeated after an interval of some days.

On account of a persistent infection it sometimes becomes necessary to carry out the entire brachyradium treatment as a series of alternative intrauterine and vaginal tentative treatments. In case of a successful tentative treatment the standard technic is used for the following treatments.

In some instances it is better to postpone the brachyradium treatment in order to give transfusions and to administer vaginal douches for several days. Blood transfusions are frequently used in the treatment of anemic patients.

Finally, there are cases in which it is better to begin with teleradium treatment directed toward the vulva.

Because of the numerous variations in the type of case, in the type of treatment and in the patient's reaction to treatment each of the mentioned varieties constitutes an individual problem. However, some typical instances which are frequently encountered may be mentioned.

A tentative intrauterine treatment preceded by vaginal douches is used in cases in which there is an offensive discharge; in all cases in which vaginal packing was inserted prior to admission in order to control hemorrhage, and in cases in which there is a large sloughing crater. When pyometra is present the first treatment should be an intrauterine application of radium. The presence of chronic salpingitis indicates the need for great care; the tentative treatment should be interrupted if there is even a slight rise in temperature.

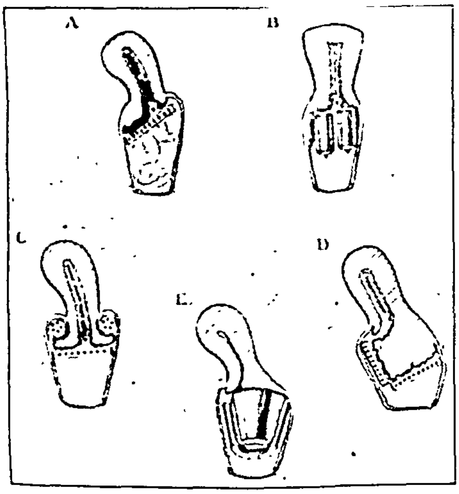

Fig. 6.—Different types of intracavitary radium application.

In lesions with a large cauliflower growth treatment is begun with vaginal douches and teleradium directed toward the vaginal inlet followed by a careful tentative vaginal treatment.

Repeated short vaginal applications preceded by teleradium treatment are suitable in cases of simultaneous extensive involvement of the vagina, offensive discharge and difficulty in finding the cervical canal.

A similarly careful treatment regimen should be adopted in cases in which there is a rise in temperature or a manifest septicemia on admission as well as in cases in which a combined brachyradium treatment according to the standard technic was interrupted because of a rise in temperature. In the first category as well as in patients with a threatening pelvic peritonitis it might be necessary to postpone the brachyradium treatment for weeks and to try to combat the infection by roentgen irradiation. It should be observed that massive roentgen irradiation directed toward the center of the pelvis necessitates a reduction of the brachyradium dose if one wishes to avoid severe injuries to the intestine.

It is an important fact that in recent years it has been considered advisable to modify the treatment technic in about 45 per cent of the total number of patients treated.

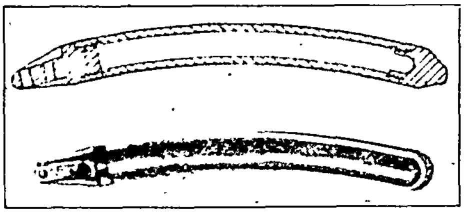

Fig. 7.—Large applicator for intrauterine treatment.

The identification of the cases in which a modified technic should be employed and the proper administration of the treatment require considerable experience. The technic must be varied from patient to patient and must be carefully planned from the beginning. The effect of the treatment must be closely watched during and after treatment. The time and type of subsequent treatments must be thoroughly considered. For the foregoing reasons top results cannot be expected unless there are available a sufficient number of beds, an ample supply of suitable radium containers and a clinic which is well organized for its special purpose. Neither can top results be expected in places where radiotherapy is handled by a young and inexperienced assistant. In surgical therapy top results are credited to the man behind the knife. It is high time that a similar view should be applied to radiotherapy.

Special attention should be devoted to cases complicated by acute salpingitis. Experience has taught that acute salpingitis contraindicates further brachyradium treatment and that there is only one way to handle such cases, namely to remove the adnexa by laparotomy and to apply radium as soon as possible after the operation.

Sixty-eight cases of cancer of the cervix were complicated by acute salpingitis (table 4). In 57 of these radical operations were not performed, and only 14 patients were alive without evidence of the disease five years after treatment. Eleven patients underwent a bilateral salpingo-oophorectomy, and 9 were alive and free from evidence of the disease five years after treatment. The striking result in the latter group is most likely accidental, but the figures suggest that in cases of acute salpingitis salpingo-oophorectomy is the correct procedure.

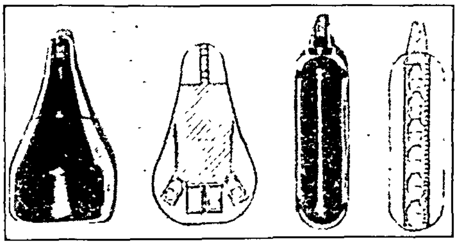

Fig. 8.—Microbomb of two different designs for vaginal application.

ized cigarets, these two groups of tests are considered together in order to increase the total experience. The systolic blood pressure in the normal persons rose 13.4 mm. of mercury, on the average, with a range of 2 to 32; in the patients with cardiac disease it rose 17.6, with a range of 6 to 34. The diastolic blood pressure in the normal subjects rose 10.0 mm. of mercury, with a range of 0 to 20; in the patients with cardiac disease it rose 11.8, with a range of 4 to 22. The heart rate in the normal subjects increased 8.5 beats per minute, with a range of minus 7 to plus 45; in the patients with cardiac disease it increased 9.4 beats per minute, with a range of minus 6 to plus 39. The cardiac output in the normal subjects decreased 1.8 per cent, with a range of minus 20.0 to plus 17.1; in the patients with cardiac disease it increased 6.4 per cent, with a range of minus 10.7 to plus 50.0.

Table 2.—*Averages of Maximal Changes Observed in Blood Pressure, Heart Rate and Cardiac Output in Normal Persons and Patients with Cardiac Disease After Smoking Regular and Denicotinized Cigarets*

Systolic Blood Pressure (Mm. Hg)

Type of Cigaret	Normal Subjects			Persons with Cardiac Disease		
	No. Tests	Average	Range	No. Tests	Average	Range
Regular	45	+13.3	+2:+32	39	+17.1	+6:+34
Denicotinized	11	+13.6	+4:+32	9	+19.6	+12:+30
Total	56	+13.4		48	+17.6	

Diastolic Blood Pressure (Mm. Hg)

Type of Cigaret	Normal Subjects			Persons with Cardiac Disease		
	No. Tests	Average	Range	No. Tests	Average	Range
Regular	45	+10.4	+4:+20	39	+12.3	+4:+22
Denicotinized	11	+ 8.3	0:+16	9	+ 9.7	+4:+18
Total	56	+10.0		48	+11.8	

Heart Rate (Beats per Minute)

Type of Cigaret	Normal Subjects			Persons with Cardiac Disease		
	No. Tests	Average	Range	No. Tests	Average	Range
Regular	45	+ 8.5	−7:+45	39	+10.2	−6:+39
Denicotinized	11	+ 7.5	0:+18	9	+ 6.3	0:+15
Total	56	+ 8.5		48	+ 9.4	

Cardiac Output (Percentage)

Type of Cigaret	Normal Subjects			Persons with Cardiac Disease		
	No. Tests	Average	Range	No. Tests	Average	Range
Regular	16	−2.2	−20.0:+17.1	15	+7.2	−10.7:+50.0
Denicotinized	4	−0.3	−11.0:+15.0	3	+2.5	− 6.0:+ 7.5
Total	20	−1.8		18	+6.4	

A casual glance at the figures suggests greater reactivity in the group with cardiac disease as compared with the normal subjects and in the group smoking regular cigarets as compared with those smoking the denicotinized variety, particularly with respect to cardiac output. However, the categories showing the greater effects are loaded because of the high values in 2 patients with cardiac disease who smoked only regular cigarets, and in each of whom only a single measure of cardiac output was made.

Significant changes in the form of the electrocardiogram were not observed in any of the subjects. In 9 normal subjects and in 9 with cardiac disease slight and varying alterations in the T waves were noted, of which the most frequent was diminished amplitude in leads 2 and 4F. The decrease rarely exceeded 2 mm. and was observed after smoking both regular and denicotinized cigarets. The greatest change was a lowering of 4 mm. noted in 1 case in lead 4F, in which the T waves were initially very high. There were no deviations of the RS-T segments. In 18 normal subjects and in 12 with cardiac disease the complexes did not show any changes. No arrhythmias occurred.

When effects on the circulation were apparent, they were observed almost invariably after smoking the first cigaret. This may be taken to indicate that, under the conditions given, there was no cumulative action of nicotine or of whatever substances may have caused the reactions. The duration of the effect on blood pressure, heart rate and cardiac output was usually between thirty and forty-five minutes. If longer, it could often be ascribed to fatigue and restlessness of the subject toward the end of the observation period. Sometimes a slight but progressive fall in output appeared to be associated with greater relaxation.

ILLUSTRATIVE PROTOCOLS

Case 1 (chart 1).—I. McK. was a woman, aged 41 years, without symptoms or signs of cardiovascular disease. She had smoked from ten to fifteen cigarets daily for the previous twenty years. She inhaled habitually and during the test. No unpleasant symptoms occurred while smoking. The maximum changes observed were: systolic blood pressure, plus 6 mm. of mercury; diastolic, plus 8; heart rate, plus 6 beats per minute; cardiac output, plus 8.8 per cent.

The changes in blood pressure and heart rate were slight; *the increase in cardiac output was within the range of normal variation.*

Case 2 (chart 2).—P. S. was a man, aged 45 years, without symptoms or signs of cardiovascular disease. He had smoked from six to ten cigarets daily for the previous twenty-five years. He inhaled habitually and during the test. No unpleasant symptoms occurred while smoking. The maximum changes observed were: systolic blood pressure, plus 28; diastolic, plus 16; heart rate, plus 14; cardiac output, minus 11.0 per cent.

Although there was a well marked rise in systolic and diastolic blood pressure, the heart rate increased only slightly and the cardiac output was diminished to a point just below the range of normal variation.

Case 3 (chart 3).—A. C. was a man, aged 43 years, with coronary heart disease. A mild attack of myocardial infarction had occurred five weeks previously; recovery was rapid and uneventful. He had smoked forty cigarets daily for the previous eighteen years, up to the time of his recent illness. He inhaled habitually and during the test. There were no unpleasant symptoms while smoking. The maximum changes observed were: systolic blood pressure, plus 8; diastolic, plus 6; heart rate, plus 6; cardiac output, plus 0.4 per cent.

The increases in blood pressure and heart rate were slight and the cardiac output remained unchanged.

Case 4 (chart 4).—W. W. was a man, aged 43 years, with coronary heart disease. A mild attack of myocardial infarction had occurred three and one-half months previously, from which he made a good recovery. But he continued to have frequent anginal pains, both on effort and at rest, culminating in a second cardiac infarct two months after these observations were made. He had smoked from thirty to forty cigarets daily for twenty-five years and continued to smoke ten or twelve each day after the first infarct occurred. He inhaled habitually and during the test. No cardiac pain was experienced while smoking. The maximum changes observed were: systolic blood pressure, plus 16; diastolic, plus 10; heart rate, plus 9; cardiac output, plus 6.0 per cent.

There were slight rises in blood pressure and heart rate but there was no increase in cardiac output beyond the range of normal variation.

Case 5 (chart 5).—M. B. was a man, aged 46 years, with coronary heart disease. A severe attack of cardiac infarction, accompanied by congestive heart failure, had occurred five and one-half weeks previously. At the time that the observations on the effects of smoking were made, the heart was well compensated and he was taking digitalis in daily maintenance doses. This was his second attack of infarction, the first having occurred five years before. He had smoked from ten to twelve cigarets daily for twenty-eight years up to the time of the recent illness. He inhaled habitually and during the test, but not deeply. While smoking he did not experience pain or other unpleasant symptoms. The maximum changes observed were: systolic blood pressure, plus 16; diastolic, plus 10; heart rate, plus 15; cardiac output, plus 50 per cent

The rises in blood pressure and heart rate were of the order noted in many other subjects, both with and without heart disease, but there was a striking increase in cardiac output.

COMMENT

It is generally agreed that smoking tobacco causes an increase in blood pressure and heart rate, and constriction of the peripheral blood vessels.[4] The only determinations of cardiac output after smoking were made by Grollman,[5] using the acetylene method. In 5 normal persons, he found no increase except in a habitual pipe smoker, who puffed vigorously on three cigars in rapid succession. Changes in the form of the electrocardiogram have been noted repeatedly and usually have been slight, consisting chiefly of lowering in the amplitude of the T waves.[6] In one healthy young man who complained of dizziness on smoking cigarets, Graybiel, Starr and White[7] observed transient inversion of the T wave in lead 2. Wilson and Johnston[8] reported 2 patients with coronary heart disease in whom smoking a cigaret induced anginal pain and produced displacement of the RS-T segments resembling that seen immediately following infarction of the heart. Such cases are rare.

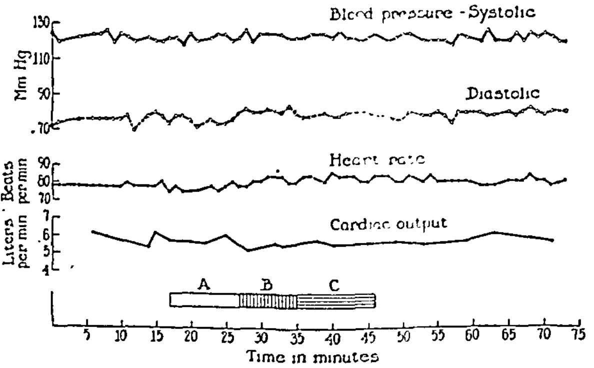

Chart 1 (case 1).—I. McK., a normal woman aged 41 years. *A*, puffing unlighted cigaret. *B*, smoking first regular cigaret. *C*, smoking second cigaret.

Haag[9] demonstrated in animals that the rises in blood pressure and vasoconstriction caused by the intravenous injection of solutions of tobacco smoke were proportional to their nicotine content. But most observers have found no appreciable differences, in man, between the reactions to smoking regular cigarets and those partially denicotinized by a commercial process.[10] There is still disagreement as to whether smoking cigarets which contain no nicotine whatever is without effect on the circulation.[6]

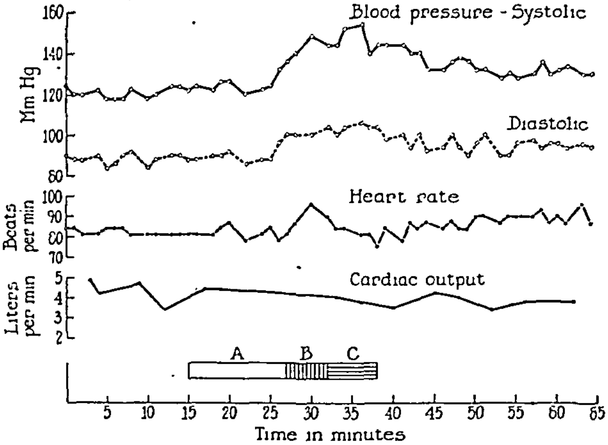

Chart 2 (case 2).—P. S., a normal man, aged 45 years. *A*, puffing unlighted cigaret. *B*, smoking first regular cigaret. *C*, smoking second cigaret.

Consideration of three factors must determine whether smoking cigarets is immediately harmful to the patient with cardiac disease: (1) the effect on the work of the heart, (2) the action on the coronary circulation and (3) individual susceptibility.

The work of the heart, under changing physiologic conditions, depends on the amount of blood ejected and the degree of peripheral resistance. The change in kinetic energy of the ejected blood is small and may be neglected. When the cardiac output is constant the increase in work is proportional to the increase in mean arterial pressure. In these circumstances it seems probable that the rise in blood pressure after smoking is the result of peripheral vasoconstriction. The average increase in pressure in our cases was approximately 15 per cent, which is no more than is caused by any mild physical effort or a slight emotional disturbance. Some evidence of effect, though not at

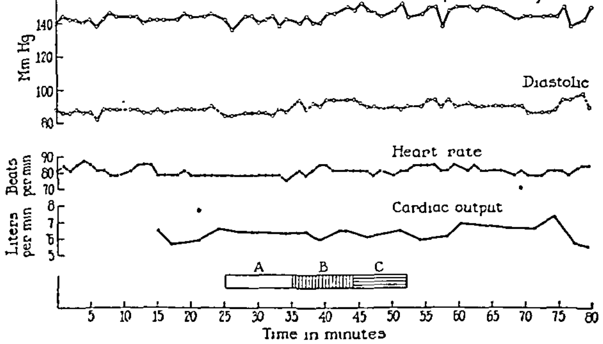

Chart 3 (case 3).—A. C., a man, aged 43 years, who had had a mild cardiac infarction five weeks previously. *A*, puffing unlighted cigaret. *B*, smoking first regular cigaret. *C*, smoking second cigaret.

maximum levels, persisted for thirty to forty-five minutes.

In 1 normal person and in 2 patients with cardiac disease the cardiac output increased significantly. In the case of the normal person, there was a rise in both systolic and diastolic pressures of 12 mm. of mercury. The output increased 17 per cent. During the test he complained of dizziness and sweating. One of the persons with cardiac disease was a man, 22 years old, with advanced though inactive rheumatic heart disease. In this case, the systolic pressure rose 22 mm. and the diastolic 18 mm.; the cardiac output increased 34 per cent. The second patient (case 5, chart 5) was recovering from a severe attack of myocardial infarction; his cardiac output increased 50 per cent. In these 3 cases the augmented output of the heart was the determining factor in causing a significant increase in cardiac work.

The electrocardiogram afforded no evidence of any intrinsic action on the heart muscle or on the coronary arteries. Cardiac pain was not experienced by any of the patients, even by those with known coronary heart disease. Anginal attacks have been ascribed to smoking and the term "tobacco angina" has occasionally been applied to such cases. The condition is certainly uncommon. Osler,[11] in his "Lectures on Angina Pectoris and Allied States," mentions only 2 instances; Allbutt[12] cites 3. Others have reported occasional cases.[13] In a few susceptible persons with diseased coronary vessels nicotine does appear to cause these arteries to constrict.[1] Anginal pain can also occur, in such cases, as the result of increasing the work of the heart sufficiently to induce coronary insufficiency. Probably both mechanisms are concerned.

That there is wide variation in susceptibility to the effects of smoking is common knowledge. Many persons do not use tobacco or discontinue smoking because of unpleasant symptoms, such as sweating, dizziness, headache, tachycardia or extrasystoles. But the vast majority, both men and women, smoke with apparent impunity and with much enjoyment.

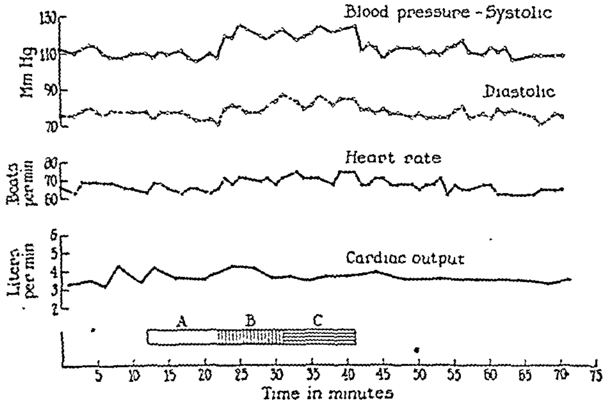

Chart 4 (case 4).—W. W., a man, aged 43 years, who had had a mild cardiac infarction three and one-half months previously. He experienced frequent anginal pains. *A*, puffing unlighted cigaret. *B*, smoking first regular cigaret. *C*, smoking second cigaret.

In this discussion, no attention has been given to the possible role of long-continued smoking in causing atherosclerosis, particularly of the coronary arteries. The evidence favoring this etiologic relationship is scant and unconvincing. For example, to infer its existence because the incidence of coronary sclerosis in young persons is higher in smokers than in nonsmokers[14] is not justified, for there are too many other unknown factors involved. It may well be that the nervous person who smokes heavily is of the constitutional type in which circulatory disease is prone to develop. In rats and rabbits, Thienes and Butt[15] found that control animals showed greater vascular degeneration than did those chronically poisoned with nicotine.

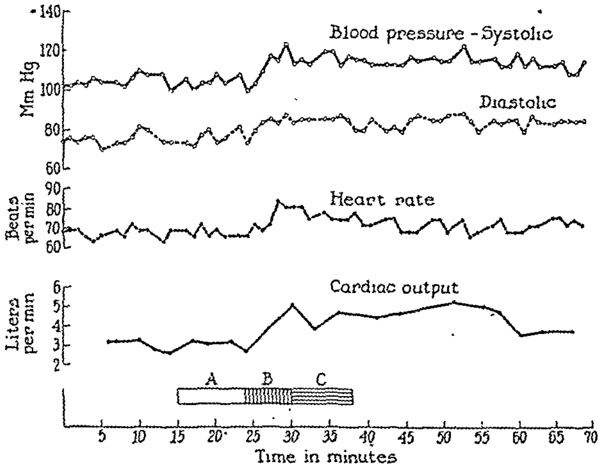

Chart 5 (case 5).—M. B., a man, aged 46 years, who had had a severe cardiac infarction five and one-half weeks previously, accompanied by congestive failure. *A*, puffing unlighted cigaret. *B*, smoking first regular cigaret. *C*, smoking second cigaret.

Our studies, then, indicate that the effects on the heart of smoking two cigarets in succession are relatively slight and are no greater in patients with heart disease than in normal persons. For the person with cardiac disease, moderation in smoking, as in other activities, is to be desired. But moderation is an indefinite term and will vary according to temperament and tolerance for tobacco.

There are certain specific conditions in which smoking should be forbidden because any increase in the work of the heart, however slight, is to be avoided. Among these are congestive heart failure, the acute stages of cardiac infarction and active rheumatic carditis. No patient with peripheral vascular disease should use tobacco because of its constricting action on the peripheral circulation. Those who are aware of discomfort after smoking will probably fare better by abstaining, regardless of the presence of a cardiac disorder. As yet, no satisfactory objective clinical test is available for selecting those who are unusually sensitive to the effects of tobacco on the heart.

SUMMARY AND CONCLUSIONS

Observations were made on the effects of smoking regular and commercially denicotinized cigarets in normal persons and in patients with various forms of cardiac disease. The indexes used were changes in cardiac output as determined by the ballistocardiograph, changes in heart rate and blood pressure and alterations in the form of the electrocardiogram.

The results were submitted to statistical analysis. There were no significant differences in response either between the normal group and the cardiac group, or between those who smoked regular and denicotinized brands.

The averages of the maximal changes observed, in both normal persons and persons with cardiac disease, showed a slight rise in systolic and diastolic blood pressures, as well as a slight increase in heart rate. In neither group was there a significant change in the average cardiac output. Changes in the form of the electrocardiogram occurred in less than half of the subjects in each group. These were slight and consisted most frequently of diminished amplitude of the T waves. Deviations of the RS-T segments were not encountered. No arrhythmias occurred.

There was considerable variability in the effects of smoking in both normal persons and persons with cardiac disease. This depended to a greater extent on individual susceptibility than on the presence of disease.

Smoking cigarets did not cause cardiac pain in any of the subjects, including those with coronary heart disease. "Tobacco angina" is extremely rare.

Except in susceptible persons, smoking cigarets causes only slight changes in the circulation and does not increase significantly the work of the heart. Because of the enjoyment afforded and the emotional satisfaction obtained, patients with inactive forms of heart disease may be permitted to smoke in moderation. This conclusion does not apply to those who suffer from peripheral vascular disorders.

The more important cardiac conditions in which smoking should be forbidden are congestive heart failure, the acute stages of cardiac infarction and active rheumatic carditis.

ABSTRACT OF DISCUSSION

DR. A. R. BARNES, Rochester, Minn.: Numerous investigations on the effect of nicotine on the circulation and metabolism in man have shown that nicotine increases the systolic blood pressure 10 to 25 mm. of mercury and the diastolic blood pressure 7 to 25 mm. of mercury. Smoking elevated the average systolic blood pressure 39.7 mm. of mercury and the diastolic blood pressure 28.1 mm. of mercury in a series of patients with hyperreactive blood pressure (Herrell and Cusick). Smoking increases the heart rate 10 to 13 beats per minute, but this increase tends to diminish with increasing age of the patient. A prompt fall in the surface temperature of the extremities follows the smoking of two cigarets and a marked peripheral vasoconstriction occurs. In patients with hyperreactive blood pressure smoking produced an average decrease of 22 per cent in the caliber of the retinal vessels. The basal metabolic rate was increased from 4 to 8 per cent by smoking. Numerous observers have reported a decrease of 1 to 4.5 mm. in the height of the T wave of the electrocardiogram following the smoking of two cigarets. I have seen occasional patients in whom smoking two cigarets would invoke an attack of angina pectoris, and similar observations have been reported by others. Most of such patients have been found to have significant elevation of blood pressure after smoking and are to be regarded as hyperreactors. It is not possible to measure the effect of nicotine in the coronary blood flow in man, but it has been shown that it decreases the blood flow in the coronary arteries of the dog. In one investigation nicotine was administered to dogs before ligation of a coronary artery, and its effects on the electrocardiogram were studied. After ligation of a coronary artery only one fourth as much nicotine as before operation was required to produce marked electrocardiographic changes. English, Willius and Berkson showed that a significantly, though not strikingly, greater number of patients with coronary disease smoked as compared to patients without coronary disease. Glendy and White compared the smoking habits of 100 patients under 40 years of age who had coronary disease with those of patients above 80 years of age and without coronary disease. Fifty-five per cent of the older group smoked as compared to 93.3 per cent of the younger group. Only 4.2 per cent of the older group were heavy users of tobacco, compared with 58 per cent of the younger group. There is no incontestable evidence that nicotine causes or intensifies the average case of coronary disease. The facts which I summarized make me cautious in concluding that I may advise patients with coronary disease that smoking is not harmful to them.

DR. DAVID ADLERSBERG, New York: Dr. Levy and co-workers found no significant differences after smoking of two cigarets in the ballistocardiogram and electrocardiogram, and no significant differences in the heart rate, blood pressure or cardiac output in normal persons and in patients with cardiac disease. They concluded that patients with inactive forms of heart disease may be permitted to smoke moderately. The data presented by the authors have been statistically evaluated. I wonder whether application of these short term experiments to the general question of smoking in disease of the coronary arteries is justified. Our knowledge of the etiology and pathogenesis of disease of the coronary arteries is limited. The situation is somewhat similar to the one that existed some years ago in the field of endocarditis. Since then we learned to separate and characterize the various forms of endocarditis on the basis of etiology, pathology, clinical course and response to therapy. Disease of the coronary arteries is at present a real *mixtum compositum*. We are probably dealing with various morbid processes which have one thing in common, the localization in the coronary arteries. It will be extremely important in the future to separate and classify these different entities. Our own studies of disease of the coronary arteries in young persons indicate that in about 30 per cent of them a hereditary disorder of the metabolism of lipids, especially of cholesterol, represents an important pathogenetic factor. Another group represents the arteritis type of disease of the coronary arteries, in some way related to thromboangiitis obliterans and/or similar forms of arterial disease. It is generally accepted that patients with peripheral vascular disease, especially thromboangiitis obliterans, should not smoke because of the constricting action of nicotine on the peripheral circulation, and Dr. Levy and other experienced clinicians forbid smoking in this disease. Since some instances of disease of the coronary arteries appear pathogenetically related to this or similar arterial diseases, I am not convinced that long-continued smoking will be tolerated without harm in all cases of chronic disease of the coronary arteries. Although the patients in Dr. Levy's group did not experience anginal pain after smoking of two cigarets, we all have had experience with heavy smokers whose attacks were greatly relieved after they stopped smoking. Dr. Levy compromises and permits patients with chronic forms of coronary heart disease to smoke "in moderation." There is no reliable criterion for the establishment of susceptibility to tobacco. Patients with disease of the coronary arteries should not smoke, as a rule. Only occasionally in tense and high strung persons, who simply cannot give up smoking because of the emotional satisfaction, may an exception to this rule be reluctantly permitted.

DR. H. S. CONNAMACHER, Newark, N. J.: In 1939, while I was spreading inorganic fertilizer, I was suddenly seized with a severe pain in the chest. The pain was coronary in character, lasting about ten minutes, and thereafter reappeared on physical exertion, excitement, chilling and lying on the left side. A cardiologist found no evidence of damage to the heart. The size, contour, electrocardiogram, blood pressure, pulse rate and auscultatory signs were all normal. A colleague, who specializes in allergy, found me slightly susceptible to tobacco, wool and dust. My tonsils were removed and their bacterial contents cultured. I was tested with these and found sensitive to hemolytic streptococci and to catarrhal cocci. I had been a moderate smoker of cigars and pipe. I discontinued smoking, but the pain diminished only gradually and did not disappear until six months had elapsed. After that I was apparently normal. Then I began to doubt that tobacco was a factor and began smoking cigars again, about two a day. In less than a week the pain was back, exactly as before. Again I stopped smoking, but the pain persisted, with gradual diminution over a period of about three months. I did not smoke any more for three years. Again I tried it and again the pain came back. This time it took four months after I stopped smoking to return to normal. The following summer I climbed Mount Washington on the Tuckerman Ravine trail, and had no more discomfort during or after the climb than any of my three apparently healthy companions. A year and a half ago I began accepting an occasional cigaret from friends—no cigars—maybe one a day or one every two days, and for about six months I had no discomfort whatever, until last July the same condition, just as severe, was back. Again I was examined by a cardiologist, who could find nothing abnormal in my heart. This time the improvement was much slower than before, the pain after one year has not yet left entirely. My reasons for bringing this to your attention now is that while smoking there were no symptoms whatever, only perfect enjoyment of the cigar or pipe. The pain in every episode did not appear until I had been smoking some days, and the pain persisted for long periods of time after the cessation of smoking. These, I believe, indicate a gradual cumulative effect, comparable to that which is found in Buerger's disease.

Dr. Herbert F. Robb, Belleville, Mich.: If the smoking of cigarets has no apparent immediate harmful effects on the heart of either the normal adult person or of those with cardiac disease, one might get the impression that smoking cigarets would have no harmful effects on any one. We should guard against such an erroneous conclusion. The effects of smoking cigarets are not only biologic. Smoking does give some persons a certain amount of emotional stability. But smoking may have physiologic, economic and moral repercussions which may be experienced to a greater degree by those in the low income group than by those who are economically secure. Although the laboratory findings may not indicate any harmful cardiac effects in the adult who smokes, nevertheless the use of cigarets by adolescents is too often disastrous in that it may mask the symptoms of existing vitamin and nutritional deficiencies, and mental and social maladjustments peculiar to that age of rapid growth and change from childhood to adulthood. Not only are there vitamin deficiencies prevalent at this age, as might be expected from the rapid increase in body growth, but also vitamin deficiencies as the result of inadequate diet. If boys or girls from 12 to 18 years of age with thiamine and other nutritional deficiencies resort to smoking for their physical and emotional stability they will take the burden off an adequate diet, their thyroid glands, adrenal glands, liver and other glands of internal secretions and their autonomic nervous system. By depending on the drug they do not develop character or physical and moral stamina to the extent that they would if they did not use it. Moderate or severe deficiencies of thiamine hydrochloride and the use of drugs to mask the symptoms are important factors in the development of delinquent children. To permit to go unchallenged the impression that smoking cigarets does no harm to youth even above 16 years of age would be to neglect an issue with which we are all concerned, namely the physical and moral stability of present and future America. We cannot consider the smoking of cigarets only from a biologic point of view. The smoking of cigarets is also a political, economic, psychiatric and moral problem, especially with youth between the ages of 12 and 18 years.

Dr. R. L. Levy, New York: It was to be expected that our point of view with regard to smoking would stimulate some dissenting comments. A number of the questions raised by the discussers are answered in the fuller paper which is to be published; a few may be touched on now. With regard to figures given in the literature indicating that the effects of smoking, both on the heart and the peripheral circulation, are less marked in the older age groups, it may be said that statistical analysis of these figures does not reveal significant differences between the reactions of the youthful and the aged. Again, because nonsmokers live longer than smokers, and because coronary sclerosis is more frequent in young persons who smoke than in those who do not, it does not necessarily follow that smoking is responsible for these differences. There are so many unknown variables, of which one of the more important is the constitutional factor. Heavy smokers may well be of the type susceptible to arterial degeneration. There are also those who are hypersensitive to the action of tobacco, as has already been indicated. Certainly it is reasonable to assume that any one who is aware of unpleasant symptoms as the result of smoking will fare better if he abstains from the use of tobacco. It is to be hoped that a simple, objective clinical test may be developed for the detection of hyperreactors to nicotine. I do not agree that most habitual smokers would rather stop entirely than indulge moderately. Many are content with a curtailed tobacco ration and obtain much pleasure from it. Over a period of years, we have seen a large number of patients with inactive cardiac lesions continue to smoke without apparent harm. Because of this fact and in the light of the observations just reported, we consider it proper, until sound evidence to the contrary is forthcoming, to permit certain of these persons to indulge in a habit which affords so much satisfaction and enjoyment.

AGRANULOCYTOSIS AND HEPATOCELLULAR JAUNDICE

Toxic Reactions Following Propylthiouracil Therapy

HAROLD J. LIVINGSTON, M.D.
and
SAUL F. LIVINGSTON, M.D.
Brooklyn

The increasing incidence of toxic reactions following thiouracil therapy is well known today. As a substitute for this drug Astwood and Vanderlaan [1] recommended propylthiouracil. There were no significant side effects encountered in their series of 100 cases. Reveno [2] in his observations on 54 patients found no evidence of toxic effect on the blood or blood-forming tissues. The only side effects encountered by the aforementioned authors were pruritus, urticaria and drug fever. Bartels [3] has given propylthiouracil to 450 patients at the Lahey Clinic with a toxicity incidence of 2 per cent. There has been 1 case of agranulocytosis, 5 cases exhibiting depressed leukocyte counts and 1 case revealing a typical fever response. In the reports received thus far, Hardy [4] knows of 1 case of agranulocytosis (Bartels') and states that a number of patients showed a drop in the leukocyte count, which soon rose despite the continuation of the drug.

It is not the intention to comment on the efficacy of propylthiouracil but to point out that toxic effects can and do occur. The most frequent and severest complications of thiouracil therapy are granulocytopenia, leukopenia, drug fever and dermatitis. The appearance of jaundice has been reported, but its incidence has been small. The patient in the case reported here developed both agranulocytosis and hepatocellular jaundice following the use of propylthiouracil.

The most effective treatment of agranulocytosis due to thiouracil has been the parenteral administration of

penicillin. Vorhaus and Rothendler[5] recommend 1,000,000 units daily instead of the 500,000 units per day suggested by the Council on Pharmacy and Chemistry of the American Medical Association.[6] Beneficial results obtained by other measures such as the administration of "pentnucleotide" N. N. R., yellow bone marrow extracts, folic acid, pyridoxine and blood transfusions have been controversial and difficult to evaluate. The most important aim is to prevent the development of overwhelming sepsis which frequently occurs when there is pronounced diminution or absence of granulocytes. Often granulocytopenia will improve spontaneously as soon as the drug is withdrawn. Recently we have observed infections in which the organisms were sensitive to penicillin, with improvement on penicillin therapy. During the course of treatment there would be a reinfection by another organism sensitive to streptomycin, and the addition of the latter drug would control the new invader. In addition to 1,000,000 units of penicillin, our patient received 1 Gm. of streptomycin a day. The presence of anemia and evidence of hepatocellular damage necessitated the use of small blood transfusions, parenteral vitamins, liver extract, dextrose and amino acids in addition to a high caloric, high vitamin diet. These measures were directed chiefly toward the maintenance of general nutrition.

REPORT OF CASE

F. M. is a white widow aged 68 with a known enlargement of the thyroid gland for the past fifteen years. In 1939 she was told that her heart rhythm was irregular and her blood pressure was elevated. She was placed on digitalis and was getting along fairly well until September 1944 when a right radical mastectomy was performed for an adenocarcinoma of the breast. She was followed in the outpatient department of a neighborhood hospital, where roentgenologic studies of her chest and bones failed to reveal any evidence of metastasis. In January 1945 she manifested signs of mild congestive cardiac failure and despite a fairly good appetite was losing weight. It was the impression that her condition was due to a thyrotoxicosis and she was given strong solution of iodine (Lugol's solution) for a period of three weeks; there was subjective and objective improvement. Thiouracil therapy was started on May 22, 1946. She received 0.2 Gm. per day for the first week, 0.3 Gm. for the second week and returned to 0.2 Gm. per day for the third week. The dosage of the drug was discontinued because the patient complained of gastrointestinal disturbances. The results of the basal metabolic studies and blood counts may be seen in table 1. In surgical consultation it was considered that surgical intervention was contraindicated because the patient was a poor operative risk. The situation was made easier because the patient refused to permit surgical intervention. Small doses of strong solution of iodine were reinstituted, and on Nov. 25, 1946 the patient was admitted to the hospital because of a poor cardiac reserve. She improved on rest in bed, a salt free diet and digitalization. Postoperative radiation to the supraclavicular area (2,538 r) and axilla (2,900 r) was completed at this time, and the patient was discharged on Dec. 18, 1946. The patient continued to take small doses of strong solution of iodine. Her appetite was good, but there was no gain in weight and her general condition of weakness and easy fatigability remained unchanged. She was readmitted to the hospital, and propylthiouracil therapy was instituted on Jan. 17, 1947. She received 200 mg. of the drug a day for the first week and 150 mg. a day thereafter until her discharge on Feb. 6, 1947. Throughout her stay the cardiac status was under control and she continued on a maintenance dose of digitalis. There was a gain in weight of 4 pounds (1.8 Kg.) and moderate improvement on discharge. Casual urine specimens were negative except for a trace of albumin on one occasion. The results of the blood counts and basal metabolic studies may be seen in table 1.

The patient was seen on Feb. 19, 1947, at which time she was extremely emotional and complained of nervousness, palpitation, weakness and rapid tiring. Physical examination revealed a well developed and fairly well nourished woman 68 years of age. There was no dyspnea, orthopnea or cyanosis. The scleras were clear. There was no exophthalmos, and ophthalmoscopic examination revealed a grade 2 fundus. The skin was warm, flushed and moist; there were fine tremors of the outstretched hands and of the extended tongue. The gums were retracted and edentulous. There was no distention of the neck veins; the thyroid gland was enlarged and asymmetric. The right lobe was nodular, about three times its normal size and extended down to and below the suprasternal notch. There was no bruit. The right breast was absent and the left was soft, with no evidence of tumefaction. The radical mastectomy scar was soft and pliable; there was no evidence of local recurrence. The lungs were clear to percussion and auscultation. The heart sounds were of fair quality with a soft systolic murmur at the apex and base. The electrocardiogram revealed an auricular fibrillation, an average ventricular rate of 80 with digitalis effect. The blood pressure was 200 systolic and 90 diastolic. On percussion the liver was palpable to 2 fingerbreadths below the right costal margin. There was no edema of the extremities.

The basal metabolic rate was plus 37 per cent, and the weight of the patient was 118 pounds (53.5 Kg.). The patient was ordered to bed for the first week with bathroom privileges and placed on a highly nutritious diet supplemented with vitamins. In addition she received sedation and was on a maintenance dose of digitalis. Treatment with propylthiouracil,[7] 150 mg. a day, was started on Feb. 29, 1947. The following two weeks showed no striking change in her general condition, and the dosage of propylthiouracil was increased to 200 mg. a day. She gained 2 pounds (0.9 Kg.) within the next two weeks and began to show definite improvement. The patient felt stronger, was able to get around much better and was less emotional. There were no complaints, but after being on the drug for six weeks there suddenly developed general malaise, chills and a temperature ranging between 103 and 104 F. Examination at this time revealed that the patient was extremely restless and toxic. Other than a moderately injected throat there was no evident gross pathologic condition to account for the symptomatology. All drugs were immediately discontinued, and a white blood count revealed a total of 1,000 cells with no granulocytes.

The patient was admitted to the Jewish Hospital of Brooklyn on April 19, 1947. She was immediately placed on a regimen of intramuscular penicillin, 1 million units daily. She continued to appear extremely toxic and was mentally confused. The tongue was coated, and a grayish exudate was present on the uvula. The temperature the first day ranged between 104 and 105 F. Another examination of the blood revealed a hemoglobin level of 60 per cent, a red blood cell count of 3.04 million and a white blood cell count of 1,050 with no granulocytes. A bone marrow aspiration revealed an absence of granulocytic elements. There were occasional degenerated myelocytes, premyelocytes and myeloblasts. There were many smudges (probably degeneration products of the granulocytic series). The megakaryocytes were normal in number, and even these showed all stages of degeneration. The erythroblastic elements were present. In addition to the penicillin, the patient received a 300 cc. transfusion of blood on the first hospital day. The following day there was an icteric tint to the scleras, and the condition of the patient remained unchanged. It was considered that the jaundice was hepatocellular and not hemolytic. This was confirmed by the reports and follow-up of the chemical studies on the blood (table 2). Streptomycin, 1 Gm. per day, given intramuscularly, was started on the third day. The patient's course continued stormy for the first week, and the temperature remained elevated (see the accompanying chart). The patient was drowsy and at times was incontinent of stools and urine.

different groups, the therapy of each type of bulbar poliomyelitis will be described separately. The predominant therapeutic problem common to all groups is the prevention or correction of hypoxia. Secondary only to this is the maintenance of nutrition and prevention of secondary infections.

I. CRANIAL NERVE NUCLEI GROUP

Bulbar poliomyelitis with involvement of the cranial nerve nuclei is the most commonly recognized type. These patients may have paralysis of any of the motor cranial nerves, producing ophthalmoplegias, facial paralysis, etc. If the tenth nerve is spared, there is little danger to life. In a facial paralysis one may have to protect the cornea of the eye by suture of the lids, but generally no special treatment is necessary. However, when the tenth cranial nerve is involved there is impairment of swallowing and faulty innervation of the larynx. This presents a serious threat to the life of the patient by obstruction of the airway.

These patients will complain of difficulty in swallowing and will have pooling of saliva in the throat. In children one frequently notes regurgitation of fluid through the nose. The speech often has a nasal quality and may be hoarse from faulty innervation of the vocal cords. An occasional patient is unable to talk. If these symptoms are mild, the patient should have a special nurse in attendance to afford constant observation. Feeding by nasal tube or parenteral administration of fluids is indicated. In selected cases of mild disease careful spoon feedings may be used.

Pooling of secretions in the throat and impaired speech indicate an impending obstruction of the airway. It has been pointed out in previous publications[3] that anxiety, restlessness and other mild encephalitic symptoms also indicate hypoxia and that these symptoms clear up after adequate oxygenation. Therefore the appearance of these symptoms in the presence of difficulty in swallowing must be interpreted as partial obstruction of the airway until proved otherwise.

Of the 183 patients with bulbar poliomyelitis, 100 had symptoms limited to the cranial nerves. There were 5 deaths in this group. Four of these deaths occurred before an airway could be secured. The fifth death occurred from aspirated vomitus occluding the tracheotomy. All 5 deaths resulted directly from obstruction of the airway.

Maintaining an unobstructed airway is of first importance in the care of these patients. Wilson[4] reviewed this problem and recommended postural drainage, aspiration of the throat and, in a few selected cases, tracheotomy. Davison,[5] Galloway,[6] Glaser[7] and Nelson-Jones and Williams[8] have also discussed the use of tracheotomy in bulbar poliomyelitis. The last-mentioned authors emphasized that tracheotomy should not be left until the patient is in extremis. In a previous publication[1] we pointed out with illustrative cases that death might occur from sudden apposition of the vocal cords before a tracheotomy could be performed. Undue delay in performing a tracheotomy may subject the patient to a severe hypoxic insult and an increased danger of pulmonary edema, which markedly reduces the chance of recovery.

For these reasons it may be wise to perform early elective (prophylactic) tracheotomy in selected cases of bulbar poliomyelitis involving the lower cranial nerves. The following criteria have been utilized by us in deciding on elective tracheotomy in bulbar poliomyelitis: recent onset of bulbar symptoms with evidence of progression of the illness during the period of observation; general appearance of toxicity, especially with high temperature and rapid pulse; progressive difficulties in swallowing or the accumulation of secretions in the throat, and mental changes, especially anxiety, apprehension, hyperactivity, confusion or euphoria in a patient with difficulty in swallowing.

The appearance of laryngeal stridor, dyspnea despite adequate chest excursions, cyanosis and severe encephalitic symptoms indicates serious obstruction of the airway and requires emergency intubation or tracheotomy. In patients with partial or complete obstruction of the airway, there are strong inspiratory efforts in an attempt to overcome the hypoxia. These inspiratory efforts in the face of an obstruction produce a relatively great negative pressure in the bronchioles and alveoli. This negative pressure in effect sucks fluid, plasma and even red blood cells out of the pulmonary capillaries into the alveoli, producing acute pulmonary edema. For this reason patients suspected of having had a period of obstruction of the airway should receive oxygen therapy, preferably under some positive pressure to combat pulmonary edema and maintain adequate oxygenation. Oxygen therapy may be given via the tracheotomy cannula by use of a tracheotomy inhalator mentioned in the next paragraph.

After a tracheotomy the patient with bulbar poliomyelitis still requires constant care by special nurses. It is necessary to continue to aspirate the accumulation of fluids in the pharynx. During the first days following a tracheotomy there often is considerable tracheal secretion requiring aspiration. The inner tracheal cannula is inspected and cleared frequently. The tracheal secretions become viscid unless the inspired air is adequately humidified. Two cold humidifiers in the average room provide adequate humidification. This method, however, makes the room uncomfortable. It is much more satisfactory to deliver moistened air and oxygen mixtures direct to the tracheotomy tube by using a tracheotomy inhalator. The apparatus used has been described in another communication.[9] The tracheotomy inhalator has the added advantage of permitting the delivery of oxygen mixtures of various percentage concentrations under optimal positive pressure. This feature is of even greater importance in patients with involvement of the autonomic centers for respiration and circulation in the medulla.

II. RESPIRATORY CENTER GROUP

Patients dying of involvement of the respiratory center have shown destruction of the ventral portion of the reticular substance of the medulla.[1] Clinically most of these patients early in the illness show evidence of involvement of the cranial nerve nuclei. They later develop, in the face of adequate airway and respiratory musculature, variations in the rate and depth of respirations with prolonged intervals between inspiration. At this point they generally show anxiety, restlessness, increasing pulse rate and some elevation of blood pressure, which are symptoms of hypoxia, even though there is no clinical cyanosis. These symptoms mean impending failure of the central respiratory mechanism. Oxygen therapy should be started or increased. The effectiveness of the oxygenation can be followed by the use of the Milliken oximeter and checked by determinations of arterial oxygen. Details of the use of the oximeter in poliomyelitis are being reported by Hemingway and Elam.[10] In brief, this instrument determines the relative concentration of oxyhemoglobin to reduced hemoglobin by means of a photoelectric cell. It helps establish the efficiency of the measures taken to promote oxygenation. It is also possible by using the oximeter to establish the need for and the effectiveness of mechanical artificial respiration.

[9] Kubicek, W. G.; Holt, G.; Elam, J.; Brown, J. R., and Gullickson, G.: Oxygen Therapy in Poliomyelitis: A Tracheotomy Inhalator, to be published.

As failure of the respiratory center in the medulla progresses, there are increasing periods of apnea with Cheyne-Stokes periodic respiration. Confusion, delirium and coma appear. Atelectasis and extensive hemorrhagic pulmonary congestion are common at this point and are indicated clinically by cyanosis and impaired chest excursion even in a mechanical respirator. These symptoms require immediate intensification of oxygen therapy. However, the concentration of oxygen used should ordinarily not exceed 60 per cent. In emergencies it may be necessary to use 100 per cent oxygen for a limited period of time. Oxygen under positive pressure of 2 to 6 cm. of water increases the exchange of gas at the alveoli. This positive pressure assists in combating pulmonary edema. If the chest excursions are not powerful enough to produce expiration against positive pressure oxygen a mechanical respirator is required. The vest type respirator or the standard iron lung type may be used. In either case the respirator flap valve should be adjusted so that alternating positive and negative pressure is applied to the chest wall in order to force expiration against the positive pressure oxygen mixture being administered via the tracheotomy. A tracheotomy is essential in any of these patients who are put in a respirator because the mechanical respiratory excursions will produce severe pulmonary edema if there is any obstruction to the airway. Any manipulation, such as frequent suction of the trachea, which interferes with oxygenation should be avoided. Sedation of patients in this group should be avoided or used with extreme caution because of the depressant effect on an already damaged respiratory center.

Of the 183 patients with bulbar poliomyelitis, 36 were classified clinically as belonging to the respiratory center group, with 69.1 per cent mortality for the group. Five of these patients were put in respirators without receiving a tracheotomy, and 100 per cent of these patients died. There was a 64.5 per cent mortality among the remaining 31 patients. Of the 36 patients in the respiratory center group, 7 had symptoms of failure of the circulatory center in addition to respiratory symptoms.

III. CIRCULATORY CENTER GROUP

During the epidemic 12 patients were seen in whom failure of circulation was the outstanding clinical finding. There was a mortality of 83.3 per cent in this group. Patients with involvement of the circulatory center present a dusky red florid appearance. The pulse rate is out of proportion to the elevation of temperature and ranges from 150 to 200. The rhythm is irregular and the pulse is thready. The blood pressure varies from elevated to low levels and the pulse pressure may be as low as 10 mm. of mercury. Anxiety and restlessness are always present. As circulatory failure progresses the patient's blood pressure drops to shock levels, the pulse becomes imperceptible and the skin becomes cold and clammy and shows mottled cyanosis. There are delirium, coma and terminal hyperthermia. Treatment in this group is unsatisfactory if the symptoms become at all severe. Intensive oxygen therapy should be instituted early, and tracheotomy should be performed on the slightest indication of obstruction of the airway. Supportive measures in combating shock have been of only temporary benefit in our experience. In cases of milder disease such measures may tide the patient over until vasomotor control is reestablished by the nervous system.

IV. ENCEPHALITIC GROUP

Encephalitic symptoms occur commonly in bulbar poliomyelitis and are universal among the more severely ill patients. In 15 of the 183 patients with bulbar poliomyelitis, the encephalitic symptoms were the outstanding clinical feature. These symptoms include anxiety, restlessness, hyperexcitability, muscular tremors and twitchings, irritability and confusion, lethargy and coma, and convulsions, especially in children. When such symptoms appear they first should be considered to be due to hypoxia even if there is no cyanosis. Such a state of hypoxia may be produced by an unrecognized partial obstruction of the airway, a failure of central control of respiration or circulation, an inadequate function of diaphragm and intercostal muscles, an acute pulmonary edema or an atelectasis and hemorrhagic pulmonary congestion. Once the exact causative factor has been discovered, the corresponding therapy can be instituted. Only when these cerebral symptoms persist after adequate oxygenation is achieved should they be ascribed to actual involvement of the cortex by the virus. Of the 15 patients with encephalitic symptoms as the outstanding manifestation only 1 died.

COMBINED BULBAR-CERVICAL CORD GROUP

Many patients with bulbar poliomyelitis also have some involvement of the spinal cord. A few have such severe involvement that they require a respirator because of paralysis of the diaphragm and intercostal muscles. These patients pose a special problem of treatment and for that reason are placed in a separate group.

These patients may also show cranial nerve palsies, encephalitic symptoms and signs of involvement of the cardiorespiratory center in addition to paralysis of the diaphragm and intercostal muscles. It is essential in these patients to insure an open airway before placing the patient in a respirator or to maintain an open airway once the patient is in the respirator. Inspiration forced by the respirator against a partially obstructed airway creates relatively marked negative pressure in the alveoli, sucking fluid out of the pulmonary capillaries and producing acute pulmonary edema. This situation can be avoided by the early use of tracheotomy. If pulmonary edema is present or suspected, oxygen therapy preferably under positive pressure should be started. A modified respirator head has been developed for these cases. To adapt the standard design respirator for a patient with a tracheotomy the upper part of the respirator head was tilted forward about 6 inches (15.2 cm.) and welded in this position. This made the patient's throat accessible as far as the sternal notch. In addition, a cone-shaped rubber collar has been substituted for the ring-shaped sponge collar in order to afford even greater access to the tracheotomy and to promote the comfort of the patient. This equipment will be described in detail in further publications.

---

[10] Hemingway, A., and Elam, J.: Pulmonary Function in Poliomyelitis: Oximetry Studies in Spinal and Bulbar Patients, to be published.

Patients in this group have great difficulty raising their tracheobronchial secretions. For this reason they are subject to atelectasis and hemorrhagic pulmonary congestion. Bronchoscopy was found to be useful in some selected cases and was done through the tracheotomy opening in some patients. It is essential to maintain high humidification of the inspired gas mixtures delivered to the tracheotomy. It is also helpful to nebulize penicillin in saline solution down the trachea at intervals. If positive pressure oxygen is used tracheally during the expiratory phase of respiration, the flap valve on the respirator should be adjusted to exert some positive pressure on the chest wall during expiration. The oximeter is of great value in estimating the efficiency of the therapeutic measures and in determining how long the patient can be left out of the respirator. It is possible to detect a fall in arterial oxygen before the patient feels fatigued and before clinical signs of hypoxia appear.

Summary of Symptoms and Treatment in Various Types of Bulbar Poliomyelitis

Symptoms	Treatment
Bulbar-Cranial Nerve Nuclei Group	
1. Difficulty in swallowing 2. Regurgitation of food and fluids through nose (particularly in children)	Parenteral feeding; nasal feeding
3. Pooling of secretions in throat (salivation?) 4. Nasal speech; hoarseness; inability to talk	Impending obstruction of airway Postural drainage; suction; elective tracheotomy
5. Stridor; dyspnea; cyanosis (obstructed airway)	Emergency intubation and/or tracheotomy
6. Anxiety and restlessness (hypoxia)	Oxygen therapy, tent, mask, etc., humidified
7. Other cranial nerve involvements; ophthalmoplegias; facial palsies	No treatment necessary
Bulbar-Respiratory Center Group	
1. Adequate function of respiratory muscles 2. Adequate airway	
3. Variations in rate and depth of respirations (impending failure; observe carefully) 4. Prolonged intervals between respirations 5. Anxiety, restlessness, increasing pulse rate (hypoxia)	Oxygen therapy (elective tracheotomy)
6. Increasing periods of apnea 7. Confusion, delirium, pulmonary congestion (anoxia) 8. Cyanosis	Tracheotomy Respirator Intensive oxygen therapy with positive pressure, if possible; sedation with extreme caution
Bulbar-Circulatory Center Group	
1. Dusky red, flushed, florid appearance 2. Rapid (150-200) pulse 3. Irregular, thready pulse 4. Elevated blood pressure; decreased pulse pressure 5. Anxiety; restlessness 6. Shocklike state (falling blood pressure, imperceptible pulse) 7. Cold, clammy, mottled cyanosis 8. Hyperthermia, delirium, coma	1. Intensive oxygen therapy (tracheotomy, if indicated) 2. Supportive measures
Bulbar-Encephalitic Group	
1. Hyperexcitability * 2. [illegible] * 3. [illegible] * 4. [illegible] * 5. Lethargy, somnolence and coma * 6. Convulsions (chiefly in children) *	Intensive oxygen therapy 1. Mask 2. Tent 3. Intranasal oxygen 4. By tracheotomy, if indicated
Bulbar-Cervical Cord Group	
1. Cranial nerve palsies (see group 1) 2. Symptoms of cardiorespiratory center involvement (see groups II and III) 3. Diaphragm and intercostal involvement	1. Early tracheotomy 2. Intensive oxygen therapy 3. Respirator

* These symptoms are usually caused by anoxia. If they persist after adequate oxygen therapy, then they are attributable to virus invasion of the cortex.

Of the 183 cases of bulbar poliomyelitis studied, there were 20 classified as belonging to this combined group, with 15 deaths. We feel that had the improved technics been available all through the epidemic some of these could have been saved.

DRUG THERAPY

The use of drugs in bulbar poliomyelitis is limited largely to prophylactic and supportive purposes. An objective evaluation of the value of these measures is not possible. There is a high percentage of pulmonary complications among the patients dying of bulbar poliomyelitis. In those patients dying during the first two weeks of their illness the common finding was hemorrhagic pulmonary congestion. Those dying after a longer illness showed more pulmonary sepsis. For this reason intramuscular injection of penicillin is useful as a prophylactic measure. In addition penicillin may be nebulized into the tracheotomy tube at regular intervals.

Whole blood transfusions, plasma and stimulants are given when indicated. It is felt that excessive intravenous administration of fluids is to be avoided when possible because of the danger of pulmonary edema.

Early in the course of the epidemic sedative drugs were used for the control of restlessness, anxiety and apprehension. However, 1 patient with bulbar poliomyelitis experienced marked respiratory depression one hour after a small dose of a sedative drug. It is felt that the damaged respiratory center is unable to tolerate depressants. For this reason sedatives should be used with extreme caution in all patients with bulbar poliomyelitis. Nursing care and acetylsalicylic acid are usually sufficient to keep most of the patients reasonably comfortable.

NUTRITION

Patients with moderately severe or severe bulbar poliomyelitis universally lose weight because of their febrile illness and their inability to swallow. During the first few days it is often found helpful to use fluids parenterally. Intravenous administration of fluids should be avoided when possible because of the danger of pulmonary edema. As soon as the patient's condition permits, feeding is instituted by nasal tube. This is continued until the patient is taking adequate amounts by mouth. The ability of the patient to swallow may be tested from time to time beginning with fluids and progressing to soft and then solid food. When swallowing is reasonably well established, the tracheotomy tube is stoppered to test the patient's airway. As soon as the patient can tolerate closure of the tube for twenty-four hours the tracheotomy tube is removed and the stoma permitted to close

SUMMARY AND CONCLUSIONS

During the 1946 epidemic of poliomyelitis, 183 patients with bulbar involvement were admitted to the University of Minnesota Hospitals. Studies on this large group of patients revealed that bulbar poliomyelitis was not a single homogeneous entity but could be divided into four groups of symptom complexes, each pointing toward involvement of a specific region of the nervous system and requiring varying treatment procedures. The suggested therapies, correlated with the symptoms generally seen, can be tabulated for each of the groups of bulbar poliomyelitis.

MADURAMYCOSIS OF TIBIA IN A NATIVE AMERICAN

JACOB KULOWSKI, M D.
St. Joseph, Mo.
and
SIDNEY STOVALL, M D
San Antonio, Texas

Maduramycosis has been considered practically synonymous with so-called Madura foot, a term coined by the natives of India in the vicinity of Madura, one of the districts in which the disease is endemic. In Bocarro's (1893) series[1] of 100 cases, 93 involved the foot, 3 the hand and 2 the leg and trunk, respectively. Fungous infections are widely distributed throughout tropical and subtropical zones. Maduramycosis is occasionally seen in Africa, Europe, South America, Mexico and the United States, chiefly in Texas. However, of the 38 cases which have been reported in this country, only 11 (Downing and Conant,[2] [1945]) can be classified as maduramycosis as proved by culture of the organism. Our case belongs in the latter category.

REPORT OF CASE

A. T., a boy aged 8 years, was born and reared in Placitas, N. Mex., and had never been out of his native state. He was admitted to the Carrie Tingley Hospital,[3] Hot Springs, N. Mex., on Oct. 8, 1946, one month after onset of a circumscribed swelling of the left leg. Prior to onset there had been no prodromal signs and symptoms or related trauma, and no systemic reaction was noted later. He had always been in good health, and the family history was noncontributory. His only complaint had been slight tenderness to firm pressure and accidental bumping of the affected region. Examination revealed a hard moderate swelling over the midanteromedial aspect of the left leg, about 2 inches (5 cm.) in diameter, which did not interfere with the gait. The overlying skin was normal, and firm pressure elicited mild tenderness.

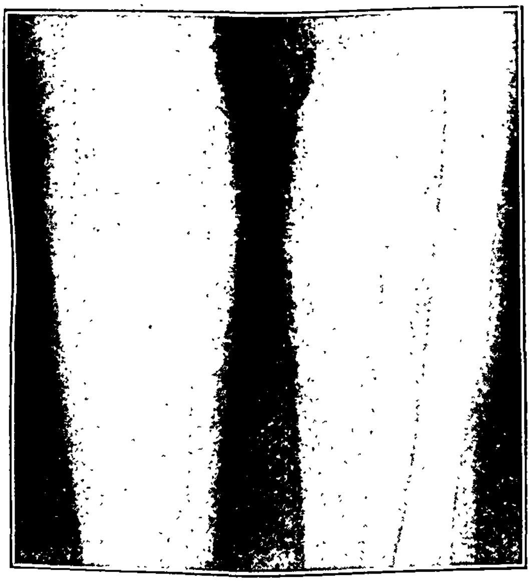

Fig. 1.—Roentgenologic appearance of the left tibial lesion (maduramycosis) one month after onset of swelling.

Roentgen examination of the left tibia (fig. 1) revealed a cystic area of destruction about 1 inch (2.5 cm.) in diameter in the cortex and adjacent medulla. The former was thickened in a fusiform manner and was perforated in front except for an intact line of periosteum. The enlargement caused a forward bulging of the bone anteriorly, which accounted for the swelling noted on physical examination. There was no abnormal soft tissue shadow in the vicinity of the cortical perforation and no periosteal reaction either locally or at a distance. The margins of the cyst were definitely limited, especially posteriorly, by a thin wall of increased density.

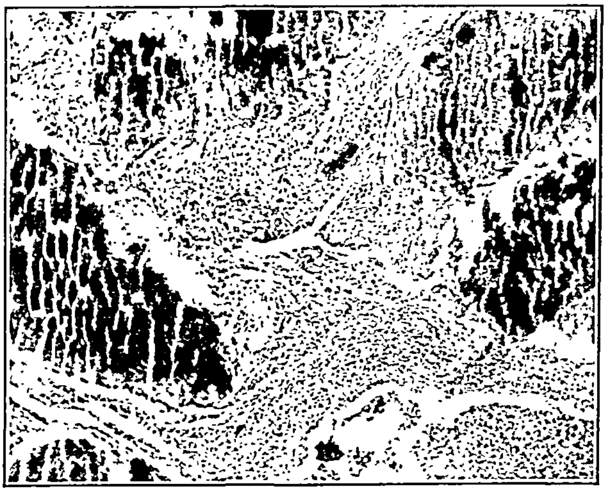

Fig. 2.—Photomicrograph (reduced from a magnification of × 95) of the soft granulomatous tissue removed at operation (maduramycosis); showing the heavy masses of coarse mycelial filaments.

The red blood cell count was 4,740,000 and the white blood cell count 8,200, with 52 per cent polymorphonuclear leukocytes, 43 per cent small lymphocytes, 1 per cent monocytes and 4 per cent eosinophils. The Kahn test of the blood and urinalysis were negative. Roentgen examination of the chest revealed no abnormalities.

A variety of conditions were considered in the differential diagnosis, which narrowed down to some unusual form of infection or possibly tumor formation. The absence of soft tissue and periosteal reaction in the face of the cortical perforation, the relatively short duration and the mild nature of the subjective symptoms, together with the reactive zone about the cystic area of destruction and its superficial resemblance to a Brodie abscess favored the diagnosis of an inflammatory lesion. Pathologic examination of the tissues was necessary to decide the issue.

On Oct. 16, 1946, with the patient under general anesthesia, the focus was subjected to exploration and excision. The soft tissues were normal. The periosteum was grayish, translucent and fluctuant. On incision, an unfamiliar black to grayish black caviar-like material exuded. The periosteum was excised, and a smooth ebonated cavity, about ¾ of an inch (1.9 cm.) in diameter and depth was entered in the tibia, in which the *remaining granular substance was evident and carefully wiped* out. The affected area was saucerized and swabbed out with iodine and alcohol. A small iodoform wick, loose closure with interrupted dermal suture, dressing and a posterior plaster splint completed the procedure. There was no local or general systemic reaction after operative intervention.

In the absence of a resident pathologist, the tissues removed at operation were sent routinely to Dr. Ashworth of Dallas, Texas. His pathologic report was as follows: "Grossly the material consisted of (1) fragments of bone with attached fibrous tissue and a thick creamy greenish yellow material weighing approximately 5 Gm. and (2) fragments of a soft friable black with intermingled grayish white tissue weighing approximately 0.5 Gm.

[2] Downing, J. G., and Conant, N. F.: Medical Progress: Mycotic Infections, New England J. Med. **233:** 153 (Aug. 2); 181 (Aug. 9.) 1945.

[3] At that time Dr. Kulowski was chief surgeon and Dr. Stovall senior resident of the Carrie Tingley Hospital.

"Microscopic examination of sections of soft tissue revealed a decided inflammatory reaction with considerable formation of granulation tissue. A few small spicules of bone were embedded in the granulation tissue. The granulation tissue was cellular, being infiltrated with numerous inflammatory cells. Multinucleated giant cells were also present in moderate numbers. Most of the inflammatory cells were lymphocytes and macrophages. There were a few areas in which large numbers of mononuclear wandering cells were present containing abundant lipoid material. These cells were similar to foam cells. Embedded in the granulation tissue there were several large bodies which had a reddish brown-staining appearance.

"These bodies were clumped together, forming a mass about 2 mm. in size. Examination of this tissue with a high power lens showed it to be composed of numerous coarse myceliums which had numerous small round and oval bodies, chlamydospores (fig. 2). Also, a small colony of similar appearance had a perfect radial arrangement of coarse eosinophilic clubs around the border. Around these colonies an encapsulation type of reaction, with giant cells, macrophages and slight suppuration, was encountered. The pathologic diagnosis was maduramycosis of the tibia."

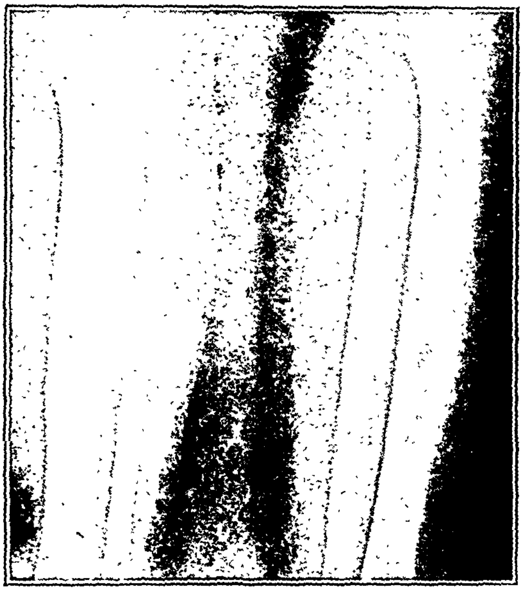

Fig. 3.—Roentgenologic appearance of the left tibial focus about six weeks after operative excision.

Since it was highly desirable, after receiving Dr. Ashworth's report, to obtain cultural confirmation, some of the material which had been removed at operation and which had been stored in a test tube at room temperature, was grown on an ordinary laboratory medium (Virginia Stovall, M.D.) and then sent to Dr. J. A. Gammel, who is an authority on this subject, for a bacteriologic report. In his letter dated Jan. 16, 1947 Dr. Gammel stated in part: "I have made a preliminary study of the cultures in the hanging drop. There is no doubt that the organism is a Madurella. I am unable to determine the type, as this requires many months of study. It differs from the two organisms I studied before, but I would not say that the difference is great enough to justify establishment of a new species. . . . You could definitely call the process a madurellamycosis."

While waiting for the pathologic report a policy of watchful observation had been adopted. The patient's postoperative convalescence had been uneventful. The iodoform wick was removed several days after the operation, and his wound healed by primary intention in two weeks. Nevertheless, because of the unusual nature of his lesion, on Oct. 29, 1946 (thirteen days after operation) penicillin 15,000 units was administered intramuscularly and continued every three hours through Nov. 7, 1946. In addition ultraviolet radiation was given locally for a brief period. He was discharged from the hospital on Nov. 9, 1946, walking in a plaster cylinder. This was removed about six weeks later, and guarded weight-bearing was advised. At that time the wound had remained perfectly healed; he had no complaints, and the general state of his health was excellent. A roentgenogram taken then (fig. 3) appeared to show slight evidence of healing but did not differ otherwise from the original. Since it is generally agreed that the disease does not tend to recur in remote parts of the body and that it seldom causes death except by cachexia or secondary infection, this patient's chances for permanent recovery seem favorable.

COMMENT

According to Scheube [4] (Clegg and Hobdy,[5] 1916) Kaempfer [6] (1712) was the first European physician to mention Madura foot. However, priority is given to Gill [7] (1842) of Madura, who called attention to the disease in a dispensary report. Colebrook [8] (1846), from the same dispensary, described what is now known as Madura foot. This disease is clinically characterized by: utter chronicity and destructiveness, enlargement and deformity, abscess and sinus formation, gradual and complete disorganization of the bones of the foot, the presence of grains, or granules, in the diseased tissues and exudates, usual absence of pain, absence of systemic reaction except in the presence of secondary infection (notwithstanding the deep infiltrative nature of the lesion) and absence of tendency toward spontaneous resolution. Carter [9] has stated that it begins as (1) a papule which becomes livid or mottled, (2) a nodule which is deep seated and fixed, (3) a vesicle surmounting a swollen, hard area or (4) an abscess which on rupture is found to be a fistula. The big toe is often affected first. The disease may then spread proximally only to the ankle and stop there for a short time; it then spreads to the knee and eventually may reach even the thigh. A case of recurrence has been observed in an amputation scar (Boyce and Surveyor,[10] 1894).

The incubation period of Madura foot varies from several days to weeks or even as long as three months. The extent of the destruction in our case would indicate that it was of more than one month's duration. The mode of transmission of the disease has not yet been determined. It is considered that evidence justifies the view of an external injury by an infected agent, such as coral or thorns. In Bocarro's series [1] 91 per cent of the patients were farmers and the remainder spent most of their time in the open. In 17 instances he noted evidence of a prick of an acacia thorn; in many of these cases he recovered the thorn itself. In our case the location of the lesion in the vicinity of the nutrient vessel, its roentgenologic appearance, the known coarseness of the myceliums of maduramycosis and the absence of trauma suggest a thromboembolic origin of the lesion. Thus the primary focus remains obscure.

The roentgenologic changes observed in Madura foot are extremely variable and, according to reports in the literature, are the result of direct infective destruction or reaction at a distance. Semon[11] (1915) found no evidence of skeletal damage after two and one-half months, although there was little doubt of bony involvement in his case. Carrion and Knott[12] (1944) found destruction, ankylosis and evidence of new bone formation in all the bones of the foot and only slight involvement of the ankle joint; but there was periosteal thickening almost throughout the entire length of both the tibia and the fibula. Shaw and MacGregor[13] (1935) noted periostitis of the fibula and chronic osteomyelitis of the tibia and tarsus, with obliteration of the articular spaces of the foot and ankle. Tribedi and Mukherjee[14] (1939) in 3 cases in persons of oriental origin described a fairly extensive patchy absorption of the tarsal bones and considerable periostitis. Likewise Gellman and Gammel[15] (1933) noted pronounced deformity of the foot with collapse of the bony elements. There was also considerable destruction of bone with evidence of bone formation in the nature of productive periostitis of the lower two-thirds of the shafts of the tibia and fibula along with fusion of the tarsus and metatarsus.

By reason of these bony changes alone the differential diagnosis involves the consideration of certain perforating ulcers of the foot: leprosy, syphilis, chromoblastomycosis and the like, mossy foot, osteomyelitis, tuberculosis and cancer. Maduramycosis should be suspected in all chronic granulomatous lesions which have not been otherwise identified. The diagnosis rests with the bacteriologic differentiation.

Van Dyke Carter's researches[9] (1860 to 1874) resulted in the recognition of the fungous character of this group of diseases. He coined the term mycetomas (fungous tumors) for the entire related group. Vincent[16] (1894) cultivated a streptothrix in a case of this variety and named it S. Madurae. In 1916 Chalmers and Archibald[17] defined mycetoma as a group name embracing the subgroup actinomycosis and maduramycosis. In 1927 Gammel[18] published an excellent review of the subject and further refined the bacteriologic aspects of this problem. He compiled a long list of etiologic fungi which were classed under nine genera. The morphologic differentiation of the mycetomas may be made on direct microscopic examination of the grains on the basis of the appearance of the mycelium and the presence or absence of chlamydospores.

All the various molds known to be pathogenic for man have one common feature; in defense against unfavorable conditions in the host or in culture they are able to form granules, or grains of various sizes, shapes and colors. These represent a colony of the infecting fungus. The word grain has become as specific as the term tubercle. It should be remembered that grains of the same color may represent entirely different specific agents in different cases. The actinomycotic mycetomas are recognized by the fine filaments, which are seldom measuring more than 1 micron in width; these mycetomas are hyaline, have a poorly defined cell membrane, are apparently nonsegmented and do not produce chlamydospores. But the maduramycotic molds contain coarse, clearly septate, branching filaments with well defined cell membranes, and they usually form chlamydospores. The ultimate identification must rest with the more refined and prolonged cultural studies performed by competent workers.

The gross and microscopic pathologic observations are fairly constant, regardless of the type of infecting fungus, except for minor details (Thompson,[19] 1928). There are a number of reports describing amputation specimens. Jones[20] (1931) could cut his specimen with a knife, the whole foot offering the consistency and resistance to cutting of cartilage. However, MacGregor[13] (1935) observed no definite extension of the disease into the bones of the foot but noted that all the joints were fused solidly. Crowell[21] (1915) found in several instances that the bones were soft and spongy below the astragalus, the marrow spaces were filled with a gelatinous material, with irregularity in bony outline or frank pus and a similar involvement of the synovial spaces.

The characteristic pathologic feature of mycetoma is essentially that of an infectious granulomatous lesion, including slowly progressive local necrosis and abscess formation, intermittent discharge through fistulous tracts of peculiar fluid and replacement of the normal tissues by granulation and fibrous tissue. The reaction is restricted to round cell infiltration, in many cases the formation of giant cells, in some the appearance of eosinophils and in all instances the production of granulation tissue and extensive scarring. Secondary infection alters the course of the local disease. A typical microsection through an abscess cavity or fistulous tract shows the grain, composed of mycelial elements, pigments and débris, suspended in fluid which fills the abscess or fistula. Suspended in the fluid also are polynuclear leukocytes and cellular débris. A zone of tissue composed of connective tissue fibrils, vascular loops and small round cells constitute the lining of the cavity or tract. External to this is a more or less distinct intermediate zone of dense connective tissue, sometimes containing eosinophils.

TREATMENT

The earliest writers on the subject of treatment agreed that excision in the early stages or amputation for the more chronic foci of Madura foot was the only treatment which gave any assurance that the disease would be controlled. The sulfonamide drugs and the antibiotics should offer some promise in the future, at least from the point of view of preventing and/or controlling concurrent secondary infection. Dixon[22] (1941) reported a case in which he treated the lesion with sulfonamide compounds. His patient remained well for eight months afterward, although her lesion had been present for fifteen years prior to sulfonamide therapy. Downing and Conant[23] (1944) also have expressed the belief that penicillin may be effective and that iodide preparations may be useful coadjuvants in the treatment, irrespective of the other therapeutic agents employed.

CONCLUSIONS

1. An unusual skeletal form of proved maduramycosis in a native American has been reported.

2. The diagnosis of similar closed lesions must rest with adequate laboratory examination of material removed surgically.

3. Open lesions always present the characteristic grains from which the diagnosis and morphologic differentiation of the mycetomas may be made on microscopic examination.

4. Early lesions respond to excision; secondary infection must be avoided.

5. The use of sulfonamide and antibiotic therapy is to be tried both prophylactically and curatively.

6. Careful clinical scrutiny of related lesions will reveal an occasional instance of these unusual infections even in native Americans.

NAIL IN DUODENUM REMOVED BY MAGNET

MURDOCK EQUEN, M.D.
ROBERT GILLIAM, M.D.
and
MERRILL LINEBACK, M.D.
Atlanta, Ga.

Once a swallowed metallic object has passed the pylorus it has been believed that the attending physician had his choice between allowing nature to take its course and calling in a general surgeon. Often of course the foreign body does pass uneventfully through the gastrointestinal tract, but if it has a point or a sharp or ragged edge there is always danger of perforation of the intestine, or, if the object is unusually long, it is always questionable whether it can pass through the fixed angulations of the duodenum. Surgical removal entails many hazards: Once the abdominal cavity of a small child is opened, it is difficult to locate a nail in the thick-walled retroperitoneal duodenum, to incise it and to suture it together; the operation carries a relatively high mortality.

Our experience with the magnet, which has so greatly simplified the removal of safety pins from the esophagus and the removal of any magnetic foreign body from the stomach, caused us to hope that the magnet might enable us to withdraw from above through natural channels ferrous objects from the duodenum. In hope of such an opportunity we had had prepared a new model of the magnet, 0.75 cm. in diameter, 3.75 cm. in length, slightly curved to facilitate its getting around curves, with a groove around one end to secure a loop of strong waxed thread.

So far as we know, no foreign body in the duodenum had ever been removed except by a formidable surgical operation prior to May 7, 1947.

REPORT OF CASE

About May 1, 1947, a boy of 4½ years was "trying to build a chicken coop." In the course of his play he managed to swallow a six penny nail. An hour later the presence of the nail in the stomach was demonstrated roentgenographically. His physician thought that the nail would pass through the intestinal tract. Two days later the nail was seen in the duodenum, point up. Daily roentgen examinations for four days showed that the nail made no progress, so on May 6 operation was planned for the following morning.

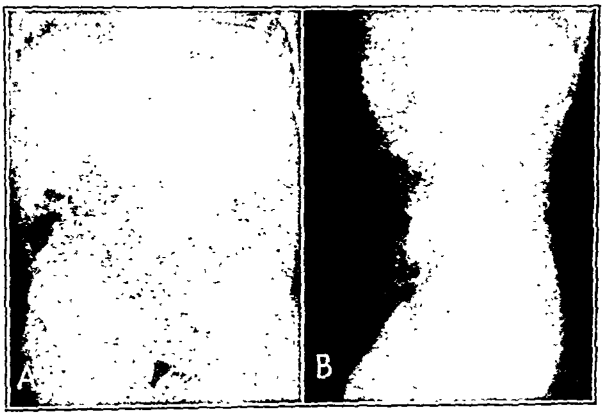

Fig. 1.—*A*, posteroanterior view shows the nail apparently in the second portion of the duodenum. *B*, the visualization of the stomach in the lateral view makes it virtually certain that the nail is in the second portion of the duodenum.

That evening the child's parents were talking with some former patients of ours, who suggested that perhaps the nail could be removed by means of the magnet. Since such a procedure seemed to them much less hazardous than the proposed operation, the next morning they brought him to Atlanta.

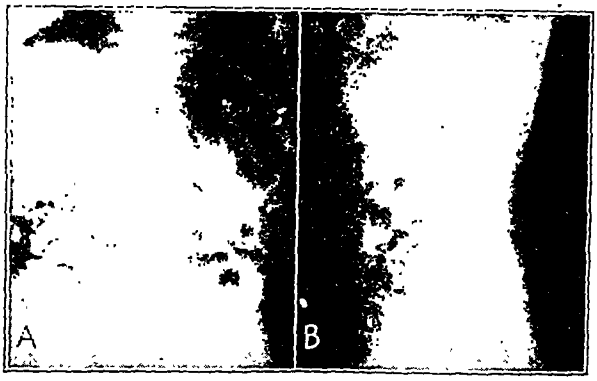

Fig. 2.—*A*, this roentgenogram taken an hour after the magnet was swallowed shows it entering the pylorus, which still contains a little of the barium. The arrow points to the groove in the magnet by which the string was attached. *B*, this lateral view shows the magnet coming down on the nail in good contact with it.

Strangely enough, the boy had had no symptoms. A flat roentgenogram of the abdomen showed the 1½ inch (3.8 cm.) nail to the right of the vertebral column, pointing medially. After he had swallowed barium (fig. 1) we felt sure that the nail was in the second portion of the duodenum, and agreed with his former physician that it could not be expected to pass further on spontaneously.

The most difficult part of the procedure was to get the little boy to swallow the new model of the magnet with waxed string attached. By 11:30 a. m. he had managed to swallow it with a thick "chocolate malted" and a caffein-containing soft drink as a chaser. An hour later a roentgenogram (fig. 2 *A*) showed the magnet in the pyloric antrum. After this the child took a nap.

Shortly before 6 p. m. he exclaimed suddenly, "Oh mama, I felt something click! I'm going to get well now!" He then complained of dull pain in the right epigastrium. A lateral view showed the magnet in contact with the nail (fig. 2 *B*).

The child was anesthetized with ether to secure perfect relaxation, and the string was tautened. Under fluoroscopic guidance the magnet and nail were slowly pulled back into the stomach. Once they were in the stomach, which was already dilated with air which he had swallowed in swallowing the magnet, we were sure of success, and magnet and nail were rapidly withdrawn. The operating time was less than two minutes.

The boy vomited a little clear green fluid a few minutes after his return to the room, and twice more in the next few hours a small amount of clear colorless fluid. The next day he was put on a liquid diet and seemed none the worse for his experience. After a day of soft diet he was sent home well.

SUMMARY

A six penny finishing nail was swallowed by a little boy, and remained in the second portion of the duodenum five or six days. The boy was persuaded to swallow a new model of the magnet attached to a string; about four and one-half hours later he felt the magnet come in contact with the nail. Under fluoroscopic guidance, magnet and nail were withdrawn in less than two minutes.

This is the first reported case in which a foreign body in the duodenum has been removed from above through the natural channels.

From the Ponce de Leon Ear, Nose & Throat Infirmary.

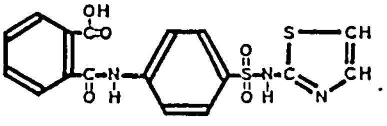
NEW AND NONOFFICIAL REMEDIES

The following additional articles have been accepted as conforming to the rules of the Council on Pharmacy and Chemistry of the American Medical Association for admission to New and Nonofficial Remedies. A copy of the rules on which the Council bases its action will be sent on application.

Austin Smith, M.D., *Secretary.*

PHTHALYLSULFATHIAZOLE.—Sulfathialidine-Sharp & Dohme.—2(N-phthalyl-sulfanilamido) thiazole.—$C_{17}H_{13}O_5N_3S_2$.—M. W. 403.42.



Phthalylsulfathiazole may be prepared by the condensation of sulfathiazole with phthalic anhydrid.

Actions and Uses.—Phthalylsulfathiazole is a derivative of sulfathiazole closely related to succinylsulfathiazole used for the oral treatment of infection in the intestinal tract. Unlike the latter, however, it is not recommended for acute bacillary dysentery or elimination of the carrier state. It is used in the management of inflammatory disease of the intestinal tract and for the reduction of coliform bacteria prior to operative procedures involving surgery of the small intestine or colon. There is clinical evidence to warrant its use as an adjunct to other measures in the control of both acute and chronic ulcerative [illegible]tis.

[illegible] is absorbed to the extent of only about 5 per cent and rarely reaches a concentration in the blood of more than 1.5 mg. per hundred cubic centimeters with doses usually prescribed. This proportion is excreted by the kidneys, mostly conjugated, which forms soluble salts in acid urine. The possibility of crystalluria is therefore remote. No toxic manifestations have been observed with therapeutic doses except where sensitivity to sulfonamides was previously acquired.

Dosage.—Orally, in tablet form, from 0.05 to 0.1 Gm. per kilogram of body weight daily. This is given in equally divided doses at intervals of four, six or eight hours, depending on the total dose to be administered. The average daily adult dose is provided by eight to twelve 0.5 Gm. tablets and should not exceed 8 Gm. Smaller doses, as indicated by response, may be continued for initial periods up to eight weeks or even longer for the management of ulcerative colitis. As a preliminary adjunct to intestinal surgery, an initial dose of 0.125 Gm. per kilogram followed by the same amount daily in divided doses given at equal intervals, comprising three, four or six doses per day, is given for a period of three to five days prior to operation.

Tests and Standards.—

Phthalylsulfathiazole occurs as an odorless, white or faintly yellowish white, crystalline powder possessing a slightly bitter taste. It may slowly darken on long exposure to light. It is slightly soluble in alcohol, very slightly soluble in ether, practically insoluble in chloroform and in water; it is ready soluble in sodium or potassium hydroxide solution, in 10 per cent ammonia solution and in concentrated hydrochloric acid.

Phthalylsulfathiazole darkens and effervesces at from 244 to 250 C. and melts at from 272 to 277 C., with decomposition, when the melting point bath is preheated to about 220 to 225 C. before immersion of the sample tube.

Place about 0.25 Gm. of phthalylsulfathiazole in a test tube and add 5 cc. of 10 per cent sodium bicarbonate [illegible] dissolves on warming and carbon dioxide i[illegible]: *from sulfanilamide, sulfathiazole, sulfapyridine,* [illegible] *ulfadiazine).*

Add 10 cc. of concentrated hydrochloric acid to about 0.5 Gm. of phthalylsulfathiazole contained in a small beaker, cover with a watch glass and heat on a steam bath until the solid has nearly all dissolved. Cool the solution, transfer to a separatory funnel and extract with two 25 cc. portions of ether, combine the extracts and evaporate to dryness: the melting point of the residue is not less than 195 C.

Dry an accurately weighed sample of phthalylsulfathiazole at 100 C. for twenty-four hours: the loss in weight does not exceed 2.0 per cent.

Ignite about 1.0 Gm. of phthalylsulfathiazole, accurately weighed. Cool, add sufficient sulfuric acid to moisten the charred mass and ignite to constant weight: the ash is not more than 0.1 per cent.

Digest 2.0 Gm. of phthalylsulfathiazole with 100 cc. of distilled water at room temperature for thirty minutes; filter. (1) To 25 cc. of filtrate add two drops of phenolphthalein solution and titrate with tenth-normal sodium hydroxide solution: not more than 1 cc. of the sodium hydroxide solution is required to produce a pink color. (2) To another 25 cc. of the filtrate add 1 cc. of nitric acid and 1 cc. of silver nitrate solution: mix well and allow to stand for five minutes protected from direct sunlight: the turbidity does not exceed that produced in a control test made with 0.1 cc. of fiftieth-normal hydrochloric acid. (3) To another 25 cc. of the filtrate add 1 cc. of diluted hydrochloric acid and 1 cc. of barium chloride solution; mix well and allow to stand for ten minutes: the turbidity does not exceed that produced in a control test made with 0.2 cc. of fiftieth-normal sulfuric acid.

Dissolve 0.5 Gm. of phthalylsulfathiazole in a mixture of 5 cc. of one-normal sodium hydroxide and 20 cc. of distilled water: the solution is clear and not more than pale yellow; add five drops of freshly prepared 10 per cent sodium sulfide solution: the darkening produced does not exceed that developed in a control test to which has been added 0.01 mg. of lead.

Accurately weigh about 1.0 Gm. of phthalylsulfathiazole, previously dried at 100 C., for four hours. Transfer the weighed sample to a 250 cc. beaker and add 20 cc. of hydrochloric acid. Cover with a watch glass and heat on a water bath for two hours. Filter the mixture into a separatory funnel. Wash the beaker and the filter paper with several portions of 10 per cent hydrochloric acid, collecting the washings in the separatory funnel. Extract the cool filtrate with five 50 cc. portions of ether, discarding the ether extracts. Heat the aqueous solution on a water bath until all of the ether is driven off. Add 5 cc. of concentrated hydrochloric acid, cool to 15 C. and slowly titrate with one-tenth molar sodium nitrite, stirring vigorously, until a blue color is produced immediately when a glass rod dipped into the titrated solution is streaked on a smear of starch-iodide paste. When the titration is complete, the end point is reproducible after the mixture has been allowed to stand for one minute. Each cubic centimeter of one-tenth molar sodium nitrite is equivalent to 0.04034 Gm. of phthalylsulfathiazole: the amount of phthalylsulfathiazole found corresponds to not less than 96 per cent nor more than 102 per cent.

Sharp & Dohme, Inc., Philadelphia

Tablets Sulfathalidine: 0.5 Gm.

U. S. Patents 2,324,013 and 2,324,015. U. S. trademark, registered.

ETHINYL ESTRADIOL (See New and Nonofficial Remedies, 1947, p. 352).

The following dosage form has been accepted:

Schering Corporation, Bloomfield, N. J.

Tablets Estinyl: 0.02 mg. and 0.05 mg.

AMINOPHYLLINE (See New and Nonofficial Remedies, 1947, p. 305).

The following dosage form has been accepted:

Ingram Laboratories, Inc., San Francisco

Ingraloids Aminophylline: Ampuls 0.243 Gm. in 2 cc. or 10 cc. and ampuls 0.486 Gm. in 2 cc., 10 cc. or 20 cc.

Council on Foods and Nutrition

ACCEPTED FOODS

The following products have been accepted as conforming to the Rules of the Council. James R. Wilson, M.D., *Secretary.*

Rochester Dairy Cooperative, Rochester, Minn.

Rochester Dairy Brand Powdered Whole Milk, Vitamin D Fortified, a powdered whole milk with vitamin D_3 added in the form of irradiated 7-dehydrocholesterol concentrate in amounts sufficient to produce a minimum of 400 U. S. P. units of vitamin D_3 per 4 ounces (124 Gm.) of whole milk powder.

Analysis (submitted by manufacturer).—Butterfat 28.00%, protein (N × 6.38) 26.20%, lactose 38.00%, minerals 5.80%, moisture 2.00%, 400 U. S. P. units of vitamin D_3 per reconstituted quart.

Calories.—5.10 per gram; 145.00 per ounce.

Golden State Company, San Francisco, Calif.

Golden State Brand Powdered Whole Milk, Vitamin D Fortified, a powdered whole milk with vitamin D added in the form of irradiated ergosterol dispersible concentrate in amounts sufficient to produce a minimum of 400 U. S. P. units of vitamin D per 4 ounces (124 Gm.) of whole milk powder.

Analysis (submitted by manufacturer).—Butterfat 28.00%, protein (N × 6.38) 26.00%, lactose 37.95%, minerals 5.80%, moisture 2.25%, 400 U. S. P. units per reconstituted quart.

Calories.—5.10 per gram; 145.00 per ounce.

Kraft Cheese Company, Chicago, Ill.

Kraft Brand Powdered Whole Milk, Vitamin D Fortified, a powdered whole milk with vitamin D added in the form of irradiated ergosterol dispersible concentrate in amounts sufficient to produce a minimum of 400 U. S. P. units of vitamin D per 4 ounces (124 Gm.) of whole milk powder.

Analysis (submitted by manufacturer).—Butterfat 28.00%, protein (N × 6.38) 26.00%, lactose 37.95%, minerals 5.80%, moisture 2.25%, 400 U. S. P. units per reconstituted quart.

Calories.—5.10 per gram; 145.00 per ounce.

IODINE AND TABLE SALT

Before modern processes for refining salt were developed, most table salt contained iodine, a natural contaminant. In regions where such salt was consumed colloid goiter was uncommon. Modern table salt is recrystallized by heating to high temperatures; any iodides contained are decomposed by these high temperatures and the iodine is lost. In the Kanawa River Valley in West Virginia salt obtained from local mines has a content of iodide representing roughly 80 parts of iodine for each million parts of salt. In the 1890s salt refined by modern methods replaced this natural product. The whiteness of the new salt together with its pouring qualities quickly overcame such competition as could be offered by the local product. Substitution of the whiter, better-pouring salt for the local product soon was followed by the appearance in this valley, apparently for the first time, of colloid goiter. The number of cases of goiter rapidly increased. In 1922, when a goiter survey was made, the prevalence of goiter proved to be as high as that in the Lake Superior region: around 60 per cent of adolescent girls had goiter.[1]

A long suspected role of iodine in the prevention of colloid goiter was established in 1916 by Marine and Kimball's[2] study of the effect of giving iodine to the children in the schools of Akron, Ohio. Development of goiter was prevented in these children. Not long afterward campaigns were undertaken to secure more adequate supplies of iodine for every one. Foods grown in goitrous regions and the water of such regions had long been shown to be poor in iodine. The addition of iodine to either foods or water offered difficulties. Finally, the iodization of table salt was selected as a satisfactory means to achieve the desired end. The campaign to popularize the use of iodized salt was instituted in the state of Michigan with results that were dramatic. Iodized salt was also used in Switzerland, where goiter was endemic; results there were encouraging. Soon thereafter, with the full cooperation of the manufacturers of salt, iodized salt was made available throughout the United States.

Lack of iodine is not the only cause of goiter. Several foods seem to be goitrogenic. Among them are the vegetables of the cabbage family and certain beans, notably soybeans. However, the effect of the goitrogens in food can be neutralized by iodine; the amount of iodine obtained by using table salt with an iodine content conforming to the standard established by the Food and Drug Administration will accomplish what is necessary. The amount of iodine is minute: 1 part of potassium iodide or suitable equivalent for each 10,000 parts of salt, representing 75 to 80 parts of iodine for each million parts of salt.

Those physicians whose experience reaches to the first two decades of this century recall the dramatic lowering of the incidence of goiter which closely followed the launching of the nationwide campaign to educate the public to make use of iodized salt. Colloid goiter, formerly so prevalent as to simulate an epidemic among adolescent girls, almost disappeared. In Chicago all the laboratory dogs were goitrous in those days; within a year or two goitrous dogs were seldom seen. The experience of the majority of the physicians active now does not extend back to that time. The public has lost interest, and use of iodized salt is said to be diminishing.

Must one wait for another goiter "epidemic" to provide the impetus for successful education of the public, or should the need for legislative action to prevent recurrence of the "epidemic" be recognized? Would universal use of salt containing iodine accomplish even more than has been accomplished up to now? Only half the table salt was iodized even at the peak of the educational campaign; although the incidence of goiter diminished greatly, goiter still continues to be prevalent. These considerations prompt the present effort to obtain federal legislation to require the presence in table salt of a satisfactory content of iodine. Although the Food and Drug Administration under the provisions of the Federal Food, Drug and Cosmetic Act of 1938 could and did establish a standard for so-called iodized salt, the law did not provide authority to interfere with the marketing of salt which was not iodized.[3] Bills (H. R. 2717 and H. R. 4211) to amend the Act to provide the necessary authority, were introduced in the last Congress. Under the latter bill table salt would be defined as a salt carrying not less than 75 and not more than 150 parts of iodine as iodide for each 1,000,000 parts of salt. The pro-

posed legislation had the support of almost every one acquainted with the health aspects of the goiter problem; it was endorsed not only by the Council on Foods and Nutrition and the Board of Trustees of the American Medical Association but also by the American Public Health Association, the Food and Nutrition Board of the National Research Council and the Association of State and Territorial Health Officers. The salt industry and a few physicians opposed, but none has offered evidence that salt which contains iodine in the small amounts proposed can be injurious. The opposition of the industry is not based on costs. The cost is minimal—so small, indeed, that for many years the market price of iodized salt has been the same as that of the uniodized product. The objections of physicians who oppose the legislation can be met by provisions which would permit the marketing of uniodized salt under some such designation as "Salt deficient in iodine."

The Council on Foods and Nutrition finds no reason to anticipate injurious effects of any kind from ingestion of iodine in the amounts obtainable from the continued use of salt iodized to the degree contemplated by the pending legislation. Occasional cases of adenomatous goiter occur, in which hyperthyroidism has developed after the medicinal use of iodine—so-called iod-Basedow—but doubt exists as to the separate entity of iod-Basedow and the part played by iodine in its production. Furthermore, in cases in which iodine has been suspected of contributing to the development of hyperthyroidism, the amount of iodine taken has been from fifty to one hundred and fifty times as much as would be obtainable from the use of table salt with no more than 160 parts of iodine for each million parts of salt. Occasional persons are hypersensitive to iodine and may react with acne to such minute amounts of iodine as are obtainable from iodized salt. However, a large experience indicates that the number of such hypersensitive persons must be very small. Some persons are sensitive to cottonseed oil, milk, eggs or other foods. They require special medical assistance, and for their special needs special foods are used. Nothing in the proposal to require the addition of iodine to table salt would interfere with the provision of uniodized salt for such special dietary purposes. Indeed, another section of the Food, Drug and Cosmetic Law (section 403J) permits the sale of foods for special dietary use when the label bears information regarding its dietary properties which will fully inform the purchaser as to its value for such use.

The proposed legislation failed in the last session of the Congress because of opposition, which it is hoped can be avoided in the future. A new bill will be introduced in the coming Congress. The members of the medical profession are urged to give this legislation their most vigorous support.

THE SITE OF INCIPIENT CLINICAL PULMONARY TUBERCULOSIS

According to the "old pathological theory" dating back as far as the postmortem findings of Morgagni in the seventeenth century, verified later by Bichat in the clinic and then by Laënnec in the nineteenth century, pulmonary tuberculosis begins in one or both apexes and spreads thence slowly in an apicocaudal direction. In the early part of the twentieth century Ghon introduced the conception of the primary pulmonary infection or complex (called the Ghon tubercle), which might be located anywhere in the lungs. In 1922, however, Assmann[1] showed that, in adults exposed to severe tuberculous infection, clinical disease most frequently began from a compact density lying infraclavicularly without a simultaneous lesion in the apex region itself.

At the congress in Wildbad in 1928, the so-called new theory was formulated, championed by Bruening, Redeker and Kayser-Petersen. The new theory maintained that pulmonary tuberculosis usually begins from an "early infiltrate" (Simon), which most often lies infraclavicularly. Accordingly, tuberculosis does not develop slowly and continuously but in leaps and bounds. No regulated connection exists between apical tuberculosis and the phthisis of the adult. The new theory, correct or not, became of great importance, since the first appearance of the "early infiltrate" is free from symptoms and most often cannot be diagnosed with the usual physical methods. Radiography increased in value, and early diagnosis became most important. Now it was impossible to wait until patients felt ill; the doctor had to go out among the apparently healthy population and seek out those who had tuberculosis.

The new theory developed mass investigation, using first the screening method and later the miniature radiologic examination. In 1938 Malmros and Hedvall[2] of Sweden reported the results of studies of many years using frequent radiographic examinations and followed from "the reversion from negative to positive tuberculin reaction right up to the appearance of incipient tuberculosis." Such careful follow-up studies proved that the disease did not start from the "early infiltrate" but from small spots, so-called initial foci, usually appearing first in the supraclavicular region or the first intercostal space or these two regions at the same time. These investigations encouraged the supporters of the old theory, especially the pathologists who had never accepted the new theory. Loeschke[3] emphasized that tuberculosis in adults always starts from small foci in the region about the apical bronchus. Kremer emphasized a disease of the apical bronchus in many cases unrecognizable in the x-ray film.

In further investigations reported in 1946 from the University Lung Clinic, Uppsala, Sweden, Hedvall[4] notes that tuberculosis in children is disappearing in Sweden and that primary tuberculosis in adults behaves in rather the same way as in children. Again he reiterates that pulmonary tuberculosis generally was found to have begun in the uppermost part of the lung and that the lesions have not shown any special preference for the immediate subclavicular region as the supporters of the new theory assert. The importance of this is to seek carefully these small foci, initial foci, otherwise many early cases of pulmonary tuberculosis will escape diagnosis.

Current Comment

PLANNING FOR THE CHRONICALLY ILL

Last week THE JOURNAL (p. 343) published a comprehensive statement on "Planning for the Chronically Ill" prepared jointly by four national organizations.[1] The statement analyzes the ever growing problem of chronic illness and makes recommendations. The problems created by chronic illness are not only medical problems but economic and social welfare problems as well. Each year chronic diseases cause almost a million deaths and the loss of almost a billion days of productive work. The average life span is much longer today than a few generations ago; as the average continues to increase, the number of persons chronically ill likewise will increase. In the year 1900 1 person in 25 was 65 years of age or older; it is estimated that by 1980 the ratio will be 1 in 10. Chronic diseases, however, kill young persons as well as the old. Perrott states that 16 per cent of all persons with known chronic diseases are under 25 years of age. From the point of view of prevalence, disability, invalidism and death, the most important chronic diseases are heart disease, arteriosclerosis, hypertension, nervous and mental diseases, arthritis, nephritis, tuberculosis, diabetes and asthma. Local governmental agencies, hospitals and physicians, as well, have been slow in recognizing and in planning to meet this great problem. The statement "Planning for the Chronically Ill" offers a guide for future legislation. The recommendations in the joint report include an intensified program for the prevention of chronic diseases and suggestions for the more constructive treatment of the medical, social and economic problems involved. The joint committee recommends a simultaneous attack on chronic illness by local, state and national organizations and government at the various levels. The statement has been approved by the House of Delegates of the American Medical Association, which authorized its members on the committee to proceed further to investigate and evaluate the problems of the chronically ill.

ANTIVIVISECTIONISM DECLARED CONTRARY TO PUBLIC INTEREST

The perpetuation of antivivisectionism depends on public subscriptions, contributions and bequests. When the money runs out, the salaried executive secretaries who promote the movement will lose interest and it will disappear. The periodic whipping-up of frenzy over alleged cruelties to animals which is staged regularly by the antivivisection organizations reflects this situation. Antivivisectionist officialdom has claimed that funds contributed to their organization should be exempt from taxation because they are given for the public benefit. In Britain the antivivisection societies made such a tax exemption claim on the ground that they were a charitable organization for the public benefit. This claim was denied by the Tax Commissioners, who were supported by the Courts. The antivivisectionists carried their appeal to Britain's highest court, the House of Lords. According to the New York *Times*,[1] the House of Lords has upheld four to one the contention of the tax authority that the antivivisection society was not an organization established for charitable purposes only. According to the New York *Times*:

> So far from being for the public benefit, the Law Lords decided, the object of the Anti-Vivisection Society was gravely injurious because, if achieved, it would be detrimental to medical science and research, and consequently to the public health.
>
> Lord Wright, delivering the majority judgment, said the society's only claim to be regarded as charitable must be the establishment of the fact that it was beneficial to the community. What it seemed to do, however, was to destroy a source of enormous blessing to mankind.
>
> He did not question that a high regard for animals was a good thing, but it must be regulated regard. Purposeless cruelty could not be forgiven, but it was impossible to apply the word "cruelty" to efforts of high minded scientists who devoted themselves to vivisection experiments for the purpose of alleviating human suffering.
>
> No one faced with the decision to choose between saving a man or an animal could hesitate to save the man.

The decision of the British House of Lords was logical. Even an extraordinary stretch of the imagination could not permit any reasoning person to believe antivivisectionism in the public interest or meriting consideration as a charitable activity. The only benefits accrued to any one arise from the salaries paid to the promoters of this antisocial movement.

ORGANIZATION SECTION

Official Notes

HOTEL RESERVATIONS FOR CLEVELAND SESSION

On advertising pages 84 and 85 will be found information concerning hotel reservations and how to secure them for the Cleveland interim session, Jan. 5-8, 1948. Every member desiring to attend that session should immediately fill in the application form in The Journal and send it to Dr. David Chambers, Chairman, Subcommittee on Hotels, 511 Terminal Tower, Cleveland 13.

Information concerning hotel reservations for the annual session in Chicago in June of 1948 cannot be published until after the close of the Cleveland interim session. Those desiring to attend the Chicago session in June would find it advantageous to await the publication of this information concerning hotel reservations before writing for reservations.

Coming Medical Meetings

Conference of State Medical Society Secretaries and Editors, Chicago, A.M.A. Headquarters, Nov. 7-8. Dr. George F. Lull, 535 N. Dearborn St., Chicago 10, Secretary.

American Academy of Dermatology and Syphilology, Chicago, Palmer House, Dec. 7-11. Dr. Earl D. Osborne, 471 Delaware Ave., Buffalo, N. Y., Secretary.

American Academy of Pediatrics, Dallas, Texas, Dec. 8-11. Dr. Clifford G. Grulee, 636 Church St., Evanston, Ill., Secretary.

American Association of Railway Surgeons, Chicago, Nov. 23-25. Dr. Raymond B. Kepner, 547 West Jackson Boulevard, Chicago 6, Secretary.

American Otorhinologic Society for the Advancement of Plastic and Reconstructive Surgery, New York, Nov. 13. Dr Norman N. Smith, 291 Whitney Ave., New Haven 11, Conn., Secretary.

American Society for the Study of Arteriosclerosis, Chicago, Hotel Knickerbocker, Nov. 2-3. Dr. O. J. Pollak, Wilmington General Hospital, Wilmington 14, Delaware, Secretary.

American Society of Anesthesiologists, New York, Hotel New Yorker, Dec. 4-5. Dr. Curtiss B. Hickcox, 745 Fifth Ave., Room 1503, New York 22, Secretary.

American Society of Clinical Pathologists, Chicago, Drake Hotel, Oct. 28-30. Dr. A. S. Giordano, 531 N. Main St., South Bend, Ind., Secretary.

American Society of Tropical Medicine, Atlanta, Ga., Dec. 2-4. Dr. Norman H. Topping, National Institute of Health, Bethesda 14, Md., Secretary.

Association of American Medical Colleges, Sun Valley, Idaho, Oct. 27-29. Dr. Fred C. Zapffe, 5 S. Wabash Ave., Chicago, Secretary.

Association of Military Surgeons of the United States, Boston, Hotel Statler, Nov. 13-15. Col. James M. Phalen, Army Medical Museum, Washington 25, D. C., Secretary.

Central Society for Clinical Research, Chicago, Drake Hotel, Oct. 30-Nov. 1. Dr. Ford K. Hick, 25 E. Washington St., Chicago 2, Secretary.

Clinical Orthopaedic Society, Indianapolis, Oct 24-25. Dr. C. R. Rountree, 1200 N. Walker St., Oklahoma City, Secretary.

Indiana State Medical Association, French Lick, Oct. 28-30. Mr. Ray E. Smith, 23 E. Ohio St., Indianapolis 4, Executive Secretary.

New England Postgraduate Assembly, Boston, Copley-Plaza Hotel, Oct. 29-31. Dr. Leroy E. Parkins, 8 Fenway, Boston 15, Chairman.

New York State Association of Public Health Laboratories, Albany, Nov. 7. Miss M. B. Kirkbride, New Scotland Ave., Albany 1, Secretary.

Oklahoma City Clinical Society, Oklahoma City, Biltmore Hotel, Oct. 27-30. Dr. Elmer R. Musick, 512 Medical Arts Bldg., Oklahoma City, Director of Clinics.

Omaha Mid-West Clinical Society, Omaha, Oct. 27-31. Dr. John M. Thomas, 1031 Medical Arts Bldg., Omaha 2, Secretary and Director of Clinics.

Post Graduate Medical Assembly of South Texas, Houston, Texas, Coliseum, Dec. 1-3. Dr. E. Trowbridge Wolf, 229 Medical Arts Bldg., Houston, Texas, Secretary.

Puerto Rico, Medical Association of, San Juan, Dec. 10-14. Dr. Jeramfel Cordero, Box 3866, Santurce, Secretary.

Radiological Society of North America, Boston, Nov. 30-Dec. 5. Dr. Donald S. Childs, 607 Medical Arts Bldg., Syracuse 2, N. Y., Secretary.

Seaboard Medical Association of Virginia and North Carolina, Virginia Beach, Va., Dec. 2-5. Dr. Clarence Porter Jones, 3117 West Ave., Newport News, Va., Secretary.

Southern Medical Association, Baltimore, Nov. 24-27. Mr. C. P. Loranz, Empire Bldg., Birmingham 3, Ala., Secretary.

Southwestern Medical Association, Phoenix, Ariz., Hotel Westward Ho, Nov. 6-8. Dr. Louis W. Breck, 116 Mills St., El Paso, Texas, Secretary.

Western Surgical Association, Colorado Springs, Broadmoor Hotel, Dec. 4-6. Dr. Warren H. Cole, 1853 West Polk St., Chicago 12, Secretary.

Southern Surgical Association, Hollywood, Fla., Dec. 9-11. Dr. Alfred Blalock, Johns Hopkins Hospital, Baltimore 5, Secretary.

Washington Letter

(From a Special Correspondent)

Oct. 16, 1947.

A. M. A. President Cites Doctors' Responsibility in Human Relations

Dr. Edward L. Bortz, President, American Medical Association, told those at the Past Presidents' Dinner of the Medical Society of the District of Columbia that physicians must exercise statesmanship in combating antisocial and unhealthy human trends. Speaking at the conclusion of the society's three day eighteenth annual scientific assembly, he said: "The degenerative lesions of the body, cancer, tuberculosis, diabetes, rheumatism and the others, will eventually yield to the neverceasing search of medical investigators. If these are brought under control, unless there is a closer understanding of human relationships at the individual and also at the national and international levels, mankind will have gained an empty victory. Society needs to mobilize its forces today for the control of antisocial and unhealthy human trends, which have brought two catastrophes within the past quarter century." Dr. Bortz said that leadership toward this objective must come from the members of the medical profession. He advocated formation of a world medical association.

General Hawley Proposed as Head of Veterans Administration

Major Gen. Paul R. Hawley, medical director of the Veterans Administration and Army chief surgeon in the European theater during the war, is being "boomed" by backers of the agency's medical program to be named administrator when General Bradley takes over as Army Chief of Staff. General Hawley indicated this week that he would like to retire, but he said that he would stay on the job as long as he considered that he was essential to continuance of the medical program. He said that he does not want the VA directorship and believed that "a new administrator should pick his own medical director." Dr. Paul B. Magnuson of Chicago, one of his principal associates in reorganization of Veterans Administration medical practice, stated his confidence that Dr. Hawley would take the top post if Mr. Truman should ask him. Dr. Hawley is credited with developing the agency's vast medical and hospital services into one of the nation's most respected medical programs. Dr. Magnuson believes that "if the program can be held together for another year, the chances are good that the program will be continued, no matter who runs the Veterans Administration or its medicine. By that time we'll have so many satisfied customers among the veteran-patients that any effort to change the program radically will be resisted by the veterans themselves."

Extra Pay for Regular Army Physicians

Physicians and dentists brought into the Army under the specialized training program do not get the $100 a month authorized by act of Congress for Regular Army medical and dental corps officers. This is reported to have caused a morale problem for the 83 per cent of the Army's 8,350 physicians and dentists not in the Regular Army. The War Department is studying the possibility of shortening to six months the one year period of training now required for transfer to the Regular Army.

Senator Flanders Finds that High Prices Cause Undernourishment

Senator Flanders, Vermont Republican who has been conducting public hearings in New York on the high cost of food and clothing, declared that food prices have climbed so high in metropolitan areas that some white collar workers and low-salaried job holders are "seriously undernourished." He described as the "submerged population" those persons whose family incomes have lagged behind the rise in the cost of living.

GOVERNMENT SERVICES

ARMY

MEETING OF LIBRARY CONSULTANTS

The fourth annual meeting of the Honorary Consultants to the Army Medical Library was held in Washington, D. C., October 10-11 under the presidency of Dr. John J. Fulton. Following meetings of the standing committees at the Library a meeting was held at the Hotel Statler. Col. Joseph G. McNinch, M.D., presented a report on the Army Medical Library; other reports were made by the chairmen of the standing committees and the secretary-treasurer. The dinner meeting was addressed by Gen. Paul Hawley, Drs. Walton B. McDaniel and Chauncey D. Leake. On Saturday at a professional meeting the following subjects were discussed: medical literature in Europe, medical abstracting, a report on UNESCO meeting in Paris, the Library's public services, sources of acquisitions, classification and historical sketch of the attempts to get a new library building.

The Surgeon General recently announced the appointment of the following Consultants to the Army Medical Library; Lieut. Col. Leon L. Gardner, M. C., U. S. A.; Dr. William S. Middleton, dean, University of Wisconsin Medical School, Madison; Dr. Benjamin Spector, professor of anatomy, Tufts College Medical School, Boston, and Mr. Wyllis E. Wright, librarian, Williams College.

Colonel McNinch, director of the Army Medical Library, and Dr. Donald O. Wagner, chief historian of the Historical Division, attended the British Empire Conference of Medical Historians, World War II, at Ottawa, Ontario, Canada, September 24-26.

CHIEF OF MEDICAL SERVICE CORPS

The Surgeon General's Office has announced the appointment of Col. Othmar F. Goriup as the first chief of the recently created Medical Service Corps of the Army Medical Department. The Medical Service Corps, which was established by the last Congress, will include commissioned specialists in various fields allied to medicine, such as bacteriologists, chemists, electronic experts, pharmacists, entomologists, psychologists and sanitary engineers. Colonel Goriup for three years during the war was chief of the Supply and Operations Division, Office of the Surgeon, Headquarters, Army Transport Command, Washington, D. C. He has a B.S. degree from St. Bonaventure and graduated in pharmacy from the University of Pittsburgh. He is a member of the American Chemical Society, the American Society of Hospital Pharmacists and the American Pharmaceutical Association.

PERSONALS

Dr. Jesse D. Stark, New York, has been appointed surgical consultant in radiology for the station hospital at the U. S. Military Academy, West Point, and consultant for the First Army headquarters at Governors Island.

Brig. Gen. Guy B. Denit has been relieved from duty in the Surgeon General's Office and assigned as surgeon, First Army headquarters, Governor's Island, New York, relieving Brig. Gen. Charles M. Walson, who has been retired.

PUBLIC HEALTH SERVICE

FUNDS FOR NONFEDERAL CANCER RESEARCH FACILITIES

The last Congress authorized the U. S. Public Health Service, through the National Cancer Institute, to grant funds for the construction of nonfederal cancer research facilities and, when necessary, for acquisition of land. While the funds appropriated for this year permit only a small beginning, the Public Health Service has written to the deans of medical schools announcing that the National Cancer Institute is prepared to receive applications for grants-in-aid to assist institutions in the construction and equipment of laboratory or clinical research buildings and the acquisition of lands therefor when facilities will be devoted exclusively to investigations of cancer. While each proposal will be studied in detail, under provision of the law, no application will be approved without recommendation by the National Advisory Cancer Council, which has established a series of principles for recommending grants for construction. While no one of the six principles will be the determining factor, they are for the guidance of applicants preparing an application for grants. Among the principles are: (1) preference to be shown for projects set up in the atmosphere of a university with a medical school; (2) preference to be shown for institutions able to contribute a large portion of the construction cost, and (3) preference to be shown for institutions actively cooperating in a state cancer control program. The next meeting of the Cancer Council will be held December 8-9, and applications to be reviewed at that time should be submitted to the National Cancer Institute, U. S. Public Health Service, Bethesda 14, Md., by November 1.

MISCELLANEOUS

SALE OF AUTOCLAVES AND STERILIZERS

About 25,000 units of government surplus unused autoclaves and sterilizers are being offered for sale at low prices by the War Assets Administration. The property ranges from small instrument sterilizers to large, hospital-type batteries and is usable for dressings, instruments, hypodermic needles and water. Included in the sale are stationary, portable and field types, operated by electricity, steam, gas, and by alcohol and gasoline-fired burners. Some are of standard construction, while others are of galvanized steel. The new, reduced, fixed prices range downward from less than half to as low as 11 per cent of acquisition costs. The prices established for priority claimants, wholesalers and exporters are subject to a 15 per cent mark-up to small retailers. Eligible nonprofit, tax exempt institutions may purchase equipment at a discount of 95 per cent. All orders received after Oct. 16, 1947, will be filled without regard to priorities. All items are sold on an "as is, where is" basis. A circular listing all items of the sale, with descriptions, acquisition costs, prices and conditions of sale, may be obtained from any War Assets Administration Customer Service Center, but all orders should be addressed to WAA Customer Service Center, 4th and Jefferson Drive, S. W., Washington 25, D. C.

SALE OF WATER PURIFICATION CAPSULES

Four hundred and eighty-five thousand packages of water purification capsules, canteen size, are now on sale as surplus government property. Each package contains a hundred capsules in vials of ten each. The price per package to wholesalers is 5 cents and to small retailers 6 cents. The minimum purchase is one thousand packages. Offers to purchase should be sent to the War Assets Administration, Customers Service Center, Army Base, Boston 10. The sale closes October 27. Physicians who are veterans and who have certain priorities in this sale must submit a photostatic copy of their honorable discharge from the service and must fill in form 1175 A entitled "Veterans Certification to Purchase Surplus Property for Business Use."

Medical News

(Physicians will confer a favor by sending for this department items of news of general interest: such as relate to society activities, new hospitals, education and public health. Programs should be received at least two weeks before the date of meeting.)

ALABAMA

Wins Prize for Book.—Dr. Wallace Marshall, Mobile, was awarded first prize for his book, "Noise of Great Waters," in the American Physicians Literary Guild competition at Atlantic City, N. J.; last June. The 600 page historical study of Mobile's role in the Civil War may soon be published. Dr. Marshall, a member of the Outagamie County Medical Society, was formerly associated with the Appleton Clinic, Appleton, Wis., and has been practicing in Mobile since 1943.

CALIFORNIA

Symposiums on Heart Disease.—The California Heart Association is sponsoring its annual postgraduate symposium on heart disease October 23-24 at Patriotic Hall, Los Angeles. Symposiums on recent advances in diagnostic procedures and on hypertension and a cardiac panel discussion are included in the program. Among others, Drs. Paul D. White, Boston, and Tinsley R. Harrison, Dallas, Texas, will take part. The meeting is open to all physicians. The fee is $15.

Air Ambulance Service.—The coast air ambulance, San Francisco, has made air ambulance service available to patients and physicians. Using San Francisco and Oakland airports as bases, the company will accept a call to or from anywhere in the United States, Canada or Mexico The company at present operates one plane, accommodating four persons. Stretcher equipment is interchangeable with land ambulances. An ambulance company of Oakland also equips the plane when needed with a portable resuscitator and an inhalator.

Public Health Training Program.—The State Department of Public Health has been granted $105,000 by the W. K. Kellogg Foundation for a four year period to finance a field training program for public health personnel. The Santa Barbara County Health Department will be a fixed station for training various types of public health personnel; disbursed training stations in other local health departments will be selected for field training. The Office of Recruitment and Training in the state health department will be responsible for general supervision of the program.

Outbreak of Conjunctivitis in Industries Checked.—Through joint action of the Division of Industrial Hygiene, Los Angeles County Health Department, the Los Angeles City Industrial Hygiene Service and the State Bureau of Adult Health, an outbreak of epidemic conjunctivitis in the Vernon area of Los Angeles County was checked. During the last two and one-half weeks in August, no new cases were reported. A total of thirty-nine cases had been definitely diagnosed and twenty-two probable cases were found in employees of twenty-seven companies in the Vernon and contiguous industrial areas. In seventeen other plants eighteen suspected cases were discovered.

COLORADO

School for Medical Record Librarians.—A twelve months' training school for medical record librarians will open Jan. 1, 1948, at the University of Colorado Medical Center, Denver. Students who have completed two years of study in an accredited college and are proficient in shorthand and typing are eligible and on graduation will receive a certificate and be prepared to take an examination leading to certification as a registered medical record librarian. The course will include three months of theory and thirty-eight weeks of internship, during which the student will learn the practical phase of the science. A limited number of scholarships will be available.

A new major course in medical records leading to the degree bachelor of science in business will also be offered by the university. Students will take the first three years of the major in medical records on the Boulder campus of the School of Business, and the fourth year at the School of Medicine in Denver. The course stresses studies in the sciences basic to an understanding of medical terminology, records and research and the aspects of business training necessary for efficient office management. The final year provides specialized training in the records division in medical terminology, all branches of hospital practice as they affect the records division, medicolegal matters, medical ethics and the organization and management of medical records departments.

CONNECTICUT

Research on Infectious Hepatitis.—Dr. Horace T. Gardner Jr., an instructor in preventive medicine, Yale School of Medicine, New Haven, has been assigned to the Army Research Laboratory in Germany to continue the joint Yale-Army investigations of infectious hepatitis. This research began in 1943 when a special commission of two members of the Yale faculty was assigned by the Virus and Rickettsial Disease Commission of the Army Epidemiological Board. Dr. Gardner received his M.D. degree from Yale in 1941 and served as a medical officer in the army for four years.

Personal.—Dr. J. Grant Irving, Hartford, has been promoted from associate medical director to medical director of the Aetna Life Insurance Company. Dr. Irving joined the company in 1935 as assistant medical director. During the war he served in the Medical Corps, Army of the United States.——Dr. John J. Dobkins, Stanford, has been appointed chief medical consultant for the Division of Rehabilitation, State Department of Education. Dr. Dobkins in 1942 entered the U. S. Army Medical Corps, in which he served four years, then took postgraduate training at Harvard Medical School, Boston.——Dr. Jan Nyboer, a clinical instructor at Yale University School of Medicine, New Haven, has been named assistant professor of pharmacology at Dartmouth Medical School, Hanover, N. H.

GEORGIA

School Year Extended.—The University of Georgia School of Medicine, Augusta, announces an addition of three weeks to its calendar, beginning 1947-1948, the increase changing the school year from thirty-three to thirty-six weeks. Classes began September 11 and will end June 19, 1948.

Personal.—Dr. G. Lombard Kelly, dean, University of Georgia School of Medicine, has been appointed as the representative of the Medical Association of Georgia to the Hospital Advisory Committee, created by act of the legislature, Feb. 1, 1946. Dr. Kelly succeeds the late Dr. Charles W. Roberts, Atlanta.——Dr. James A. Paullin, professor of clinical medicine, Emory University School of Medicine, Atlanta, and former president of the American Medical Association, has been appointed a member of the Federal Hospital Council of the U. S. Public Health Service to succeed Mrs. Evelyn Hicks of Birmingham, whose term has expired.

ILLINOIS

The First State Sanatorium.—Plans for the construction of the first state tuberculosis sanatorium in Illinois at Mount Vernon, adjacent to the proposed Good Samaritan Hospital, were approved October 3. The two hundred bed, fireproof building to be operated under the supervision of the State Department of Public Health will have an outpatient department, facilities for medical and surgical treatment, occupational therapy and rehabilitation services. About $872,000 has been requested from the federal government to meet the cost of construction. The remainder will come from state funds which have already been appropriated.

Graduate Conference at Effingham.—The seventh councilor district of the Illinois State Medical Society will hold a graduate conference at Benwood Hotel, Effingham, October 30, beginning at noon and extending into the evening. Speakers on the program, all from Chicago, will be: Dr. James J. Callahan, "Fractures"; Dr. Harry M. Hedge, "Dermatoses as Seen in General Practice"; Dr. Richard K. Gilchrist, "Rectal Surgery," and Dr. H. William Elghammer, "Progress in Pediatrics." At the evening meeting Dr. Irving H. Neece, Decatur, will speak on "Tumors of the Kidney" and Dr. Marino F. Vidoli, Decatur, on "Pathologic Discussion of Tumors."

Chicago

The Nineteenth Belfield Memorial Lecture.—Dr. Hans Selye, University of Montreal, Montreal, Canada, delivered the nineteenth annual William T. Belfield Memorial Lecture on "The Role of Hormones in Hypertension" at the regular meeting of the Chicago Urological Society October 16 at the Palmer House.

Dr. Gardner Appointed Department Head.—Dr. George H. Gardner, professor of gynecology, Northwestern University Medical School, has been appointed chairman of the department of obstetrics and gynecology, succeeding Dr. Arthur H. Curtis, who has retired. Dr. Gardner has been professor of gynecology at Northwestern since 1946, assistant dean of the medical school since 1942 and a member of the faculty since 1927. He received his medical degree from Johns Hopkins University, Baltimore, 1921, and has been in practice in Chicago since 1926.

Laboratory for Study of Physical Environment.—The University of Illinois College of Medicine broke ground September 26 for the erection of a $400,000 laboratory for the study of physical environment in health and disease. The laboratory, to be known as the Aero Medical and Atmospheric Institute, will be equipped with apparatus for the study of aviation medicine and the study of cold, heat and barometric changes. The building, 146 by 55 feet, will be adjacent to the Research and Educational Hospitals, University of Illinois, and the college of medicine.

Address on the Porphyrin Problem.—The Institute of Medicine of Chicago and the Chicago Society of Internal Medicine will hear Dr. Cecil J. Watson, professor of medicine, University of Minnesota Medical School, Minneapolis, Friday evening, October 24, at the Palmer House. His subject will be "Some Aspects of the Porphyrin Problem in Relation to Disease." This address is in addition to the regularly scheduled lecture in the series, "Where We Stand in Medicine Today," which will be delivered in the afternoon in the assembly room of the institute.

Dr. Brunschwig Goes to Cornell.—Dr. Alexander Brunschwig, formerly professor of surgery at the University of Chicago School of Medicine, has been appointed professor of clinical surgery at Cornell University Medical College and head of the department of surgery at Memorial Hospital for the Treatment of Cancer and Allied Diseases, New York. Dr. Brunschwig, a graduate of Rush Medical College, Chicago, 1926, was on the staff of Boston City Hospital before he came to the University of Chicago. He was a fellow of the National Research Council with Professor Rene Leriche in Strasbourg, France, 1930 to 1931, and has served on the staffs of the Chicago Clinics and Albert Merritt Billings Hospital, Chicago.

Dr. Miller to Head Department of Psychology.—Dr. James G. Miller, chief, clinical psychology section, neuropsychiatric division, central office of the Veterans Administration, Washington, D. C., has been appointed chairman of the department of psychology at the University of Chicago effective Jan. 1, 1948. Dr. Miller received his master's degree in psychology in 1938 and his doctor of medicine degree cum laude in 1942 from Harvard University, Boston, where he subsequently taught psychiatry and psychology. He gave the Lowell lectures in Boston in 1944 on "The Psychology of Reason and Belief." He served in the medical corps of the Army of the United States during World War II.

The Annual Ranson Lecture.—The annual Ranson Lecture in neurology will be given October 24 at 5 p.m. in Archibald Church library, Northwestern University Medical School, by Dr. Francis J. Braceland, professor of psychiatry in the Mayo Foundation Graduate School, University of Minnesota, on "The Practice of Psychiatry." The lecture is open to the public. Dr. Braceland is consulting psychiatrist to the Mayo Clinic, Rochester, Minn., and secretary of the American Board of Psychiatry and Neurology. He served as chief of neuropsychiatry, Bureau of Medicine and Surgery, Navy Department, during the recent war. The Ranson lectureship was named in honor of the late Dr. Stephen W. Ranson, professor of neurology and chairman of the medical school's Institute of Neurology. It is sponsored by the Phi Beta Pi medical fraternity.

MAINE

Clinical Session at Lewiston.—A Clinical Session sponsored by the Androscoggin County Medical Society will be held November 9-10 in Lewiston with clinics at Central Maine General and St. Mary's General hospitals. Subjects under discussion Monday include the use of contact lenses, advances in anesthesia, rapid treatment of syphilis, surgical treatment of gastric lesions, treatment of hip injuries, cardiac conditions in children, use of radioactive substances in treatment of blood dyscrasias and treatment of resistant genitourinary tract infections. The dinner speaker November 9 at the Hotel DeWitt will be Dr. Ashley W. Oughterson, New Haven, Conn., "Medical Aspects of the Atomic Bomb." Dr. Dwight E. Harken, Boston, will speak at the dinner at Mansion House, Poland Spring, Monday on "Cardiovascular Surgery."

MARYLAND

Bone Tumor Seminar.—A seminar on bone tumors will be held as a joint session between the District of Columbia and Baltimore City Pathology Societies, October 25 at the University of Maryland Dental Building, Baltimore. Dr. Henry S. Jaffe, New York, will act as moderator. A series of slides of the cases to be considered are being mailed to the members of both societies before the meeting.

MICHIGAN

Dr. Altland Named Acting State Health Commissioner. Dr. John K. Altland, former director of the Bureau of Local Health Services, was appointed September 22 acting commissioner of the Michigan Department of Health, succeeding Dr. William DeKleine, commissioner since 1944. Dr. Altland attended the University of Michigan Medical School, Ann Arbor, and interned at St. Mary's Hospital, Grand Rapids. After practicing in Lowell, he returned to the University of Michigan, receiving his masters degree in public health in 1938. He served as director of the Grand Traverse County Health Department for two years and the Barry County Health Department for six years, one and a half of which were spent with the United States Coast Guard and the United States Public Health Service. He came to the Michigan Department of Health as director of the Bureau of Local Health Services in April 1946.

MISSISSIPPI

Personal.—Dr. Felix J. Underwood, Jackson, vice chairman of the Mississippi State Medical Board and executive officer of the Mississippi State Board of Health, has been made a member of the State Medical Education Board.

Loans for Medical Students.—All medical students interested in applying for loans to become effective in February and March, 1948, must file applications by Nov. 1, 1947, for consideration by the board. Deadline for receipt of applications for midyear loans was set by the State Medical Education Board as Dec. 20, 1947, with receipt of all credentials for applications then pending set at Jan. 8, 1948.

NEW YORK

Courtland County Eliminates Raw Milk.—The Courtland County Health Department, which issued no permits for the sale of raw milk last year, is among the first to attain this protection for citizens. In at least ten other counties 99 per cent of the milk sold under permit is pasteurized.

Discontinue Distribution of Antipneumococcus Serums.—Because of a continuing decrease in the demand for antipneumococcus serums, the Division of Laboratories and Research of the New York State Department of Health will discontinue general distribution of the product. During the last twelve years serums for thirty-one types have been furnished. As long as the supply on hand lasts, serums for types 1 through 33, with the exception of 26 and 30, will be supplied from the Central Laboratory, Albany, and the Branch Laboratory, New York, for the treatment of special types of pneumonia.

Graduate Teaching Day for Monroe County.—The state medical society and the state health department have arranged a graduate teaching day for Monroe County Medical Society November 13 at the Rochester Academy of Medicine Building. At 11 o'clock Dr. Paul Reznikoff, New York, will speak on "Diagnosis and Treatment of Anemia"; Dr. Clarence E. de la Chapelle, New York, will follow with "Management of Acute Cardiovascular Emergencies." In the afternoon Dr. George E. Anderson, Brooklyn, will speak on "Diabetes Mellitus, Its Modern Interpretation and Treatment"; Dr. Edward J. Stieglitz, Bethesda, Md., on "Health in an Aging Population," and Dr. H. McLeod Riggins, New York, "Asymptomatic Thoracic Diseases."

New York City

United Hospital Fund Campaign.—On October 8 the United Hospital Fund inaugurated its annual campaign to meet the operating deficits of its eighty-nine voluntary hospitals in 1947. Under the direction of William H. Jackson, president of New York Hospital, the fund will seek $2,383,887. The voluntary hospitals gave medical care to more than a million New Yorkers of all races and creeds last year.

Dr. Browder Appointed Director of Surgery.—Dr. E. Jefferson Browder, professor of clinical surgery, Long Island College of Medicine, New York, has been appointed director of surgery on the college division of the Kings County Hospital, succeeding Dr. Robert F. Barber, retired. Dr. Browder received his medical degree from Johns Hopkins University School of Medicine in 1920. He is director of the neurological unit at the Brooklyn Hospital and director of neurosurgery at the Kings County Hospital, as well as consultant neurosurgeon to various hospitals in the city.

Academy Section on Microbiology.—The New York Academy of Medicine formally approved the organization of a section on microbiology at the stated meeting, May 1, 1947, following a request submitted to the council by thirty-three physicians. The organizers of the section, who will serve as officers pro tem until the official election in May, 1948, are: Drs. Gregory Shwartzman, chairman, and Harry Most, secretary, along with an advisory committee. The scope of the section will encompass bacteriology, mycology and parasitology, viruses and rickettsial maladies of unknown etiology, immunology, chemotherapy, pathology relative to microbiology and methods of study adopted from related sciences. The section meets on the third Wednesday of each month during the academic year.

NEW MEXICO

Establish Lovelace Foundation at Albuquerque.—The Lovelace Foundation for Medical Education and Research was established at Albuquerque on September 25, when the board of trustees held its first meeting. The foundation is the outgrowth of the Lovelace Clinic, founded in 1922 and heretofore privately owned by Drs. William R. Lovelace, William R. Lovelace II and Edgar T. Lassetter, who have "irrevocably given and donated . . . all physical assets, medical and research equipment, library and other things of value heretofore belonging to them personally and used by them in the practice of medicine and surgery." The clinic will now be operated under the direction of a board of governors, and all income, after deducting operating expenses, will accrue to the Lovelace Foundation. The twenty-two physicians on the staff will provide diagnosis and treatment on a fully paid, partly paid or free basis, depending on individual circumstances and regardless of creed, race or station in life. The foundation's objectives will be research on the causes, prevention, relief and therapy of human disease; research in aviation medicine; promotion of public health; instruction for practicing physicians in conjunction with an approved medical school; study of the effect on health of residence in the Southwestern United States, with special emphasis on its relation to arthritis, sinusitis and diseases of the chest; cancer detection and treatment, and the dissemination of information derived from these activities. Fellowships will be awarded to enable young physicians to take graduate training at the clinic in preparation for recognition as qualified specialists, through affiliation with an approved medical school.

OHIO

Director of University Hospitals.—Dr. William B. Seymour has been appointed director of University Hospitals, Cleveland, effective November 1, succeeding Dr. Ralph H. Bishop Jr., who has become head of a new committee to establish a Medical Center in Cleveland. Dr. Seymour, a graduate of Western Reserve University School of Medicine, Cleveland, was assistant director under Dr. Bishop during the war and held a position on the faculty, senior clinical instructor in medicine, Western Reserve School of Medicine. He was an intern at the New Haven Hospital in Connecticut, 1935-1937, then became assistant resident in medicine at University Hospitals, Cleveland, for one year.

Fels Institute Research Laboratories Dedicated.—New research laboratories for the Fels Research Institute for the study of human development, Yellow Springs (The Journal, May 25, 1946, p. 348) were dedicated October 17. Margaret Mead, Ph.D., New York, anthropologist of the American Museum of National History and formerly executive secretary, Committee on Food Habits of the National Research Council, gave the address. The institute is part of the program of the Samuel S. Fels Fund of Philadelphia. A dinner in honor of Dr. Fels was given by the board of trustees and the faculty of Antioch College that evening.

PENNSYLVANIA

Society News.—At the meeting of the Pennsylvania Association of Clinical Pathologists in Pittsburgh, September 13-14, Dr. Frederick O. Zillessen, Easton, was elected president; Dr. Theodore R. Helmbold, Pittsburgh, vice president, and Dr. Henry F. Hunt, Danville, secretary-treasurer.——At the recent annual meeting of the Pennsylvania Radiological Society the following officers were elected: Dr. Ralph D. Bacon, Erie, president; Dr. Leslie H. Osmond, Pittsburgh, president-elect, and Dr. James M. Converse, Williamsport, secretary-treasurer. The next annual meeting will be held at Erie, May 21-22, 1948.

Philadelphia

Alvarenga Prize Awarded to Dr. Aronson.—In recognition of his studies on the evaluation of BCG vaccine in the control of tuberculosis the College of Physicians of Philadelphia on July 14, 1947, awarded the Alvarenga Prize to Dr. Joseph D. Aronson, Wayne, of the U. S. Bureau of Indian Affairs. The Alvarenga Prize was established by the will of Pedro Francisco daCosta Alvarenga of Lisbon, Portugal, an associate fellow of the Philadelphia College of Physicians, to be awarded annually by the College on each anniversary of the testator's death, which occurred July 14, 1883.

SOUTH CAROLINA

Sixth Annual Postgraduate Seminar at Charleston.—The sixth annual Postgraduate Seminar of the Alumni Association of the Medical College of the State of South Carolina, Charleston, will be held at the college November 4-6. The out-of-state speakers will be:

Brian B. Blades, Washington, D. C., Surgical Treatment of Bronchiectasis.
Richard B. Cattell, Boston, Carcinoma of the Colon and Rectum.
Frank R. Ober, Boston, Arthritis from the General Practitioner's Point of View.
John L. Parks, Washington, D. C., Danger Signals in Obstetric Practice.
Arild E. Hansen, Galveston, Tex., Rheumatic Fever.
Colin M. MacLeod, New York, Control of Respiratory Infections.
Marion A. Blankenhorn, Cincinnati, Anuria and the Management of Acute Suppression of Urine.
Henry B. Mulholland, Charlottesville, Va., Treatment of Diabetes Mellitus.

At the Founders Day banquet, Francis Marion Hotel, the speaker will be Herman G. Weiskotten, dean and professor of pathology, Syracuse University College of Medicine, Syracuse, N.Y.

WISCONSIN

Faculty Promotions.—The University of Wisconsin Medical School, Madison, has announced the promotion of Dr. Marc J. Musser Jr. to associate professor of medicine; Dr. Carl S. Harper to associate professor of obstetrics and gynecology; Edgar J. Witzemann, Ph.D., to professor of physiologic chemistry; Dr. Ezra E. Neff to professor of surgery; Drs. Noel A. Gillespie and Clayton P. Wangeman to associate professors of surgery, and Van R. Potter, Ph.D., to professor of cancer research.

GENERAL

Diabetes Association Moves Office.—The American Diabetes Association, Inc., has moved its executive offices from Cincinnati to 1 Nevins Street, Brooklyn 17, N. Y. Dr. Edward S. Dillon, Philadelphia, is president; Dr. George E. Anderson, Brooklyn, secretary, and Dr. William Muhlberg, Cincinnati, treasurer.

Tuberculosis Scholarships.—The National Tuberculosis Association has awarded three scholarships to physicians for a four week study in the Trudeau School of Tuberculosis at Saranac Lake, N. Y., and two weeks' additional study at Bellevue Hospital, New York. The physicians are Drs. Ralph M. Overstreet Jr., West Palm Beach, Fla.; E. Harold Laws, Seattle, and Gaza E. Buda, Stratford, Conn.

Occupational Therapy Convention.—The American Occupational Therapy Association will hold its convention November 3 to 5 at the Hotel del Coronado, San Diego, Calif., under the presidency of Winifred C. Kahmann. Subjects to be discussed include Some Aspects of the Role of a Psychiatrist in Present Day Society, Medical Rehabilitation of Paraplegics, Importance of Occupational Therapy as a Basic Unit of Physical Medicine and Occupational Medicine in Poliomyelitis.

National Committee for Mental Hygiene.—This organization will hold its annual meeting in New York, November 12-13, with representatives of government, industry, medicine, education and religion addressing the sessions. Among the speakers will be Dr. Milton J. E. Senn, New York, Dr. Frederick W. Dershimer, Wilmington, Del., Dr. Arthur H. Ruggles, Providence, R. I., Dr. Erich Lindemann, Boston, Drs. Soloman W. Ginsburg, and Frank Fremont-Smith, both of New York, Dr. Jonathan C. Meakins, Montreal, Canada, and Dr. Harry S. Sullivan, Washington, D. C.

Prize Essays in Urology.—The American Urological Association offers an annual award of $1,000 (first prize $500, second prize $300 and third prize $200) for essays on the result of clinical or laboratory research in urology. Competition is limited to urologists who have been in practice for not more than five years and to residents in urology in recognized hospitals. The first prize essay will appear on the program of the forthcoming meeting of the American Urological Association, to be held at the Hotel Statler, Boston, May 17-20, 1948. Essays must be in the hands of Dr. Thomas D. Moore, 899 Madison Avenue, Memphis, Tenn., before March 1, 1948.

Society Elections.—The American Congress of Physical Medicine at its annual meeting in Minneapolis, September 2-6, elected Drs. O. Leonard Huddleston, Los Angeles, president-elect; William B. Snow, New York, vice president, and Richard Kovacs, New York, secretary.——The American Hospital

Association at the annual convention in St. Louis on September 25 made Graham L. Davis, director, hospital division, the W. K. Kellogg Foundation, Battle Creek, Mich., president; Joseph G. Norby, superintendent, Columbia Hospital, Milwaukee, president-elect, and Dr. Arthur C. Bachmeyer, director, University of Chicago Clinics, treasurer (re-elected).——At the recent meeting of the American Gastro-Enterological Association, Dr. Henry L. Bockus, professor of gastroenterology, graduate school, University of Pennsylvania, Philadelphia, became president.——Dr. Dallas B. Phemister, Chicago, was made president-elect of the American College of Surgeons at their meeting in New York September 11. Dr. Howard A. Peterson, New York, and Dr. Carl H. McCaskey, Indianapolis, were chosen first and second vice presidents, respectively.

Prevalence of Poliomyelitis.—Reports of cases of poliomyelitis for the periods indicated have been received from the division of public health methods, U. S. Public Health Service:

Regional Meeting of College of Physicians.—The Midwest Regional Meeting of the American College of Physicians will be held at the Schroeder Hotel, Milwaukee, Wis., November 15. Speakers addressing the sessions by invitation are:

Drs. Stanley H. Gumbiner and Raymond N. Hench, Chicago, Endocarditis in the Elderly.
Kenneth Gorrigan, Ph.D., Harper Hospital, Detroit, Diagnostic Use of Radioactive Tracers.
Dr. William H. Beierwaltes, Ann Arbor, Mich., Present Status of Antithyroid Drugs.
Dr. Erwin Levin, Chicago, Effect of Enterogastrone on Gastric Secretion in Man.
Van R. Potter, Ph.D., Madison, Wis., Enzyme Studies in the Cancer Problem.
Drs. Danely P. Slaughter and Edson F. Fowler, Chicago, Studies on the Effect of Estrogens and Androgens on Mammary Cancer.
Dr. Clayton G. Loosli, Chicago, Value of Vaccination Against Epidemic Influenza.
Dr. Armand J. Quick, Milwaukee, Classification of Congenital Hypoprothrombinemia.
Dr. Sidney Friedlaender, Detroit, The Newer Antihistaminic Drugs.
Dr. Walter D. Hawk and Alden K. Boor, Ph.D., Chicago, Protective Action of Penicillin Against Bacterial Endotoxins.

Meeting on Arteriosclerosis.—The American Society for the Study of Arteriosclerosis will hold its second meeting at the Hotel Knickerbocker, Chicago, November 2-3, under the presidency of Dr. Wilhelm C. Hueper, New York. The program comprises four sessions on the anatomic, physiologic, metabolic and therapeutic considerations in the study of arteriosclerosis. Speakers addressing the sessions by invitation are:

S. J. Slinger and K. G. Gartley, London, Ontario, Canada, Experimental Coronary Arteriosclerosis in Cockerels.
Melvin H. Knisely, Ph.D., Chicago, Reduced Nutrition of the Vessel Walls as Result of Intravascular Agglutination.
Boris Schwartz, Ph.D., New York, Effect of Arteriosclerosis on Dynamics of Hypertension in the Aged.
Kenneth R. Andrews and Patrick J. V. Corcoran, St. Louis, Effect of Choline, Lipocaic, Inositol and Betaine on Cholesterol Atherosclerosis in the Rabbit.
Louis Horlick, Chicago, Role of the Thyroid in Experimental Atherosclerosis in the Chick.
M. Chieffi, St. Louis, General Oxidative Processes with Relation to Degenerative Changes in the Body.
Howard Lindberg and William B. Wartman, Chicago, Study of Renal Biopsies in Relation to Preoperative Observation and Postoperative Results of Sympathectomy.

At the banquet Sunday night at 7:30 Dr. Hans Selye, Montreal, Canada, will give an address on "Hormonal Factors in Hypertension."

LATIN AMERICA

American Otolaryngologists Visit The Argentine.—The "Club ORL of Buenos Aires" inaugurated a program to extend the study of otolaryngology and relative fields of medicine, to organize courses and conferences and to offer grants to foreigners to study in Argentina. The club meets monthly and has its own scientific journal. The Club ORL a group of otolaryngologists under the leadership of Professor Juan M. Tato, started a series of courses given by physicians from the United States by inviting, in July, 1946, Dr. George Kelemen, Boston, to give a course in pathologic anatomy of the ear, nose and throat. Dorothy Wolff, Ph.D., New York, followed with another course on pathologic anatomy of the ear in Argentina, Brazil, Uruguay and Chile. The third invitation was extended to Dr. Arthur W. Proetz, St. Louis, who lectured in November 1946 on physiopathology of the nose and accessory sinuses. The fourth invitation was extended to Dr. LeRoy A. Schall, Boston, who in July 1947 delivered lectures and demonstrated operations on patients and on the cadaver in Rio de Janeiro, Montevideo, Buenos Aires, other cities of Argentina and later in Chile and Peru.

Dr. Theodore Walsh, St. Louis, invited by the Otolaryngology Society of Argentina, delivered a series of lectures in various hospitals and scientific institutions. These lectures were accompanied with demonstrations of operative technic on patients and on the cadaver. The journeys of Professors Walsh and Schall were partly sponsored by the State Department in Washington in consideration of the cultural importance of these missions. All other expenses were met by subscriptions on the part of specialists interested in these courses in the different countries in proportion to the time given to each of them. Among the other lecturers before the club were physicians from Brazil and Chile.

Marriages

William Allen Howard to Miss Marion McAlpine Rowcliffe, both of Washington, D. C., September 5.

John Philip Timpane, Troy, N. Y., to Miss Lillian Geraldine McKenna of Belleville, N. J., August 14.

Abraham J. Kaufman, Carbondale, Pa., to Miss Shirley Zemel of South Orange, N. J., August 24.

Merle Elmer Pickett, Langhorne, Pa., to Miss Bertha Mae Shelor in Roanoke, Va., September 13.

Everett F. Conlogue to Mrs. Virginia D. Routzong, both of Dayton, Ohio, September 16.

Richard Scotlar Troxel to Miss Stella Boyko, both of Allentown, Pa., September 13.

Franklin W. F. Caird to Miss Katherine W. Regnier, both of Troy, N. Y., August 20.

Mark E. Conan to Miss Patricia Ann Eagan, both of Syracuse, N. Y., August 23.

Deaths

Daniel Lesesne Smith Sr., Spartanburg, S. C.; born in St. Stephens, S. C., July 28, 1877; Medical College of the State of South Carolina, Charleston, 1903; member of the American Medical Association, charter member of the American Academy of Pediatrics; served as a member of the state board of health; past president of the South Carolina Medical Association; helped to organize the Southern Pediatric Seminar in 1921; served as chairman of the section on pediatrics of the Southern Medical Association; physician in charge and owner of the Infants and Children's Sanitarium and medical director of the Spartanburg Baby Hospital in Saluda, N. C.; one of the board of directors of the Tubercular Sanitarium of South Carolina; attending physician of Cedar Springs for Blind, Deaf and Dumb Children; specialist certified by the American Board of Pediatrics; died in Asheville, N. C, July 7, aged 69, of heart disease.

Daniel Alison Sinclair ⊕ New York; born in Detroit Nov. 18, 1871; Columbia University College of Physicians and Surgeons, New York, 1896; served as professor of urology and president of the faculty at the New York Polyclinic Medical School and Hospital; member of the American Urological Association; specialist certified by the American Board of Urology; decorated by the French government and the recipient of British decorations for service overseas during World War I; served on the staffs of the Morrisania and Misericordia hospitals; at one time consulting surgeon for the U. S. Public Health Service at Marine Hospital, Staten Island; died July 17, aged 75, of carcinoma of the lung

Thomas Henry Farrell ⊕ Utica, N. Y.; born in Detroit, Sept. 1, 1868; Queen's University Faculty of Medicine, Kingston, Ontario, Canada, 1895; specialist certified by the American Board of Otolaryngology; member of the American Laryngological, Rhinological and Otological Society; fellow of the American College of Surgeons; member of the House of Delegates of the American Medical Association; consultant at the Marcy (N. Y.) State Hospital; on the staff of the Faxton Hospital; died in Constableville June 28, aged 78, of chest injuries received in an automobile accident

Henry Clifford Sauls ⊕ Atlanta, Ga ; born in Marietta, Ga., Feb. 28, 1887; Atlanta College of Physicians and Surgeons, 1913; associate professor of clinical medicine at the Emory University School of Medicine; specialist certified by the American Board of Internal Medicine; fellow of the American College of Physicians; past president of the Fulton County Medical Society; served during World War I; on the staffs of Scottish Rite Hospital for Crippled Children, Decatur, Grady Hospital, and the Piedmont Hospital, where he died July 15, aged 60, of cerebral hemorrhage

Samuel Feldman, New York; born 1877; Cornell University Medical College, New York, 1904; specialist certified by the American Board of Dermatology and Syphilology; member of the American Academy of Dermatology and Syphilology and the New York Academy of Medicine; past president of the Bronx Dermatological Society; formerly on the faculty at Fordham University School of Medicine; affiliated with Morrisania City, Bronx and Lebanon hospitals and the Home and Hospital of the Daughters of Jacob; died in Lake Mohegan, July 27, aged 69, of acute coronary occlusion.

Harold Foster Dunlap ⊕ Indianapolis; Indiana University School of Medicine, Indianapolis, 1920; specialist certified by the American Board of Internal Medicine; fellow of the American College of Physicians; associate in medicine at his alma mater; at one time affiliated with the Mayo Foundation in Rochester, Minn.; since 1935 consulting internist at the Florence Crittenton Home; on the staffs of St. Vincent's Hospital, Indianapolis City Hospital and Methodist Episcopal Hospital, where he died July 22, aged 51, of cerebral hemorrhage and cardiovascular disease.

Claude Bernard Bowyer ⊕ Stonega, Va.; Medical College of Virginia, Richmond, 1906; past president of the Medical Society of Virginia and the state health department; trustee of the Emory and Henry College in Emory, Medical College of Virginia in Richmond and the Johnston Memorial Hospital in Abingdon; chief surgeon at the Interstate Railroad and Stonega Coke and Coal Company; died suddenly, July 29, aged 66.

George Hiram Bradley, Cincinnati; Miami Medical College, Cincinnati, 1909; for many years in charge of the post-office first aid unit; died July 30, aged 77, of uremia and arteriosclerosis.

William Harvey Bruce, Pennington Gap, Va.; University of Louisville (Ky.) Medical Department, 1912; member of the American Medical Association; died in Norton, July 28, aged 58.

Frank E. Bunting, Mandan, N. D.; Detroit College of Medicine, 1888; served as county health officer; on the staff of the Mandan Deaconess Hospital; died July 18, aged 83, of coronary occlusion.

William M. Byne, Griffin, Ga.; Louisville (Ky.) Medical College, 1891; died May 8, aged 78, of diabetes mellitus.

Donald Brett Cragin ⊕ Hartford, Conn.; Harvard Medical School, Boston, 1902; fellow of the American College of Surgeons; served as president and vice president of the Association of Life Insurance Medical Directors; past president of the local board of health; for many years medical director of the Aetna Life Insurance Company; a captain in the medical corps of the U. S. Army during World War I; consulting surgeon for the Hartford Hospital; trustee at the Hartford Dispensary; died July 13, aged 71.

James Slater Crawford ⊕ Pittsburgh; Western Pennsylvania Medical College, Pittsburgh, 1899; served during World War I; lieutenant colonel, medical reserve corps, not on active duty, and medical examiner for a draft board during World War II; formerly chief of the South Side Hospital; died July 12, aged 71, of coronary thrombosis.

John Henry Evans ⊕ Chicago; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1908; fellow of the American College of Surgeons; served during World War I; affiliated with the Oak Park (Ill.) Hospital and the Franklin Boulevard Hospital; died in River Forest, Ill., July 14, aged 61, of coronary thrombosis.

Robert Galen Davis, Baltimore; College of Physicians and Surgeons, Baltimore, 1882; died in West Baltimore Hospital July 19, aged 88, of a hip fracture received in a fall.

William Thomas Dean, St. Louis; St. Louis University School of Medicine, 1912; died July 6, aged 60, of coronary thrombosis.

William Lorne Deeton, Cleveland; University of Toronto Faculty of Medicine, Toronto, Canada, 1926; member of the American Medical Association and the American Academy of Ophthalmology and Otolaryngology; specialist certified by the American Board of Otolaryngology; served as captain in the Ohio State National Guard; on the staffs of Woman's Hospital and Cleveland Clinic; died July 28, aged 47, following a fall.

Margaret Jean Delmore, Uniontown, Pa.; Woman's Medical College of Pennsylvania, Philadelphia, 1899; died July 11, aged 72, of chronic nephritis, uremia and generalized arteriosclerosis.

Walter Martin Dickerson, Armstrong, Mo.; St. Louis College of Physicians and Surgeons, 1897; died in the Lee Hospital, Fayette, July 14, aged 72, of coronary occlusion.

Emil J. Doll, Louisville, Ky.; Hospital College of Medicine, Louisville, 1904; died in St. Anthony's Hospital July 7, aged 67, of strangulated hernia.

Herman August Drechsler, St. Paul; University of Minnesota College of Medicine and Surgery, Minneapolis, 1902; past president of the Ramsey County Surgical Society; for many years medical director of the Samaritan Hospital and on the staffs of West Side General and St. Paul hospitals; died in St. Barnabas Hospital, Minneapolis, June 15, aged 70, of heart disease.

Leland Creason Edmonds ⊕ Horton, Kan.; St. Louis University School of Medicine, 1926; served as president of the Horton High School Board; affiliated with the Horton Hospital; died July 9, aged 45, of cerebral hemorrhage.

William Young Finch ⊕ Manhasset, N. Y.; College of Physicians and Surgeons, medical department of Columbia College, New York, 1894; veteran of the Spanish-American War; died June 29, aged 75, of cerebral thrombosis, arteriosclerosis and hypertrophy of the prostate.

Carroll Harold Fowlkes ⊕ Richmond, Va.; Medical College of Virginia, Richmond, 1910; served during World War I; affiliated with the Johnston-Willis Hospital; died in Columbia July 5, aged 59, of coronary thrombosis.

John Walter Fulwiler, Bloomington, Ill.; Rush Medical College, Chicago, 1896; served three terms as county physician; local examiner for many life insurance companies, including the Prudential, which awarded him a diamond medal for thirty years' service; local surgeon for the Illinois Central Railroad; on the first staff and for many years a member at the Brokaw Hospital, Normal, where he died July 16, aged 80, of carcinoma of the prostate.

Harry Charles Galey, Key West, Fla.; University of Pennsylvania School of Medicine, Philadelphia, 1915; member of the American Medical Association; served as mayor and health officer of Key West; formerly affiliated with the U. S. Public Health Service; died July 30, aged 61, of coronary thrombosis.

John Frederick Gernhardt, Los Angeles; Fort Worth School of Medicine, Medical Department of Texas Christian University, Fort Worth, 1916; medical director and owner of the Los Angeles Sanitarium; died in the White Memorial Hospital July 14, aged 69, of diabetes mellitus.

George Lewis Gibbs, Sun Prairie, Wis.; the Hahnemann Medical College and Hospital, Chicago, 1890; died July 17, aged 80, of cerebral hemorrhage.

Arthur Howard Gollmar, Manteno, Ill.; Rush Medical College, Chicago, 1900; member of the American Medical Association; affiliated with the Manteno State Hospital; died July 24, aged 74, of coronary thrombosis.

George Munro Goodwin ⊕ New York; Columbia University College of Physicians and Surgeons, New York, 1911; specialist certified by the American Board of Internal Medicine; fellow of the American College of Physicians; affiliated with the New York Orthopaedic Dispensary and Hospital and St. Luke's Hospital, where he died July 12, aged 59, of dissecting aneurysm of the abdominal aorta.

Vivian Verne Grant, Oklahoma City; University Medical College of Kansas City, Mo., 1907; served during World War I; affiliated with Capitol Hill General Hospital; died in Providence Hospital, Waco, Texas, July 31, aged 65, of myocardial infarction.

Eugene R. Gravelly, Batesville, Ark.; Meharry Medical College, Nashville, Tenn., 1908; at one time a missionary in Africa; died July 4, aged 74.

Charles Taylor Graves, Monongahela, Pa.; University of Pennsylvania Department of Medicine, Philadelphia, 1895; served as member and president of the school board; on the staff of the Monongahela Hospital; died in St. Petersburg, Fla., July 4, aged 76, of coronary thrombosis.

James Millard Graybeal, Marion, Va.; University of Tennessee Medical Department, Nashville, 1901; on the staff of the Lee Memorial Hospital; died July 6, aged 70, of carcinoma of the prostate and pelvic bones.

Elbert Paul Green, Birmingham, Ala.; Birmingham Medical College, 1911; served during World War I, member of the American Medical Association; on the staffs of Baptist and Jefferson hospitals; died in the Veterans Hospital, Tuscaloosa, July 10, aged 66, of cerebral hemorrhage and arteriosclerosis.

Edward Walter Griffin, Townsend, Tenn.; University of Georgia Medical Department, Augusta, 1900; served during World War I; major, medical reserve corps, not on active duty; member of the American Medical Association; died in Cartersville, Ga., July 3, aged 74, of injuries received in an automobile accident.

John Jacob Gurtov ⊕ New York; Yale University School of Medicine, New Haven, Conn., 1910; specialist certified by the American Board of Otolaryngology; fellow of the American Academy of Ophthalmology and Otolaryngology; for many years on the staff of the Manhattan Eye, Ear and Throat Hospital; died July 28, aged 67, of uremia and acute pyelonephritis.

Benjamin Sargent Hanna, Norfolk, Va.; College of Physicians and Surgeons, Baltimore, 1912; formerly affiliated with the U. S. Public Health Service; served during World War I; died July 14, aged 72, of arteriosclerosis and gastric ulcer.

Charles Wilson Harper, Chipley, Fla.; University of Georgia Medical Department, Augusta, 1914; died in Sea Grove Beach, July 16, aged 56.

Frank James Rohner, Iowa City; State University of Iowa College of Medicine, Iowa City, 1912; specialist certified by the American Board of Internal Medicine; member of the Central Society of Clincal Research and the American Medical Association; fellow of the American College of Surgeons; formerly on the faculty of his alma mater; on the staff of Mercy Hospital; died July 1, aged 64, of hypostatic pneumonia.

Edward Everett Rowell ⊕ Stamford, Conn.; Hahnemann Medical College and Hospital of Philadelphia, 1899; specialist certified by the American Board of Radiology, Inc.; member of the American Roentgen Ray Society and Radiological Society of North America, Inc.; fellow of the American College of Radiology; formerly health officer; served overseas during World War I; radiologist on the staffs of Greenwich (Conn.) Hospital, Norwalk (Conn.) General Hospital and St. Joseph's Hospital; died July 13, aged 68, of lymphosarcoma.

Alfred Schwab, New York; Columbia University College of Physicians and Surgeons, New York, 1896; Bellevue Hospital Medical College, New York, 1896; died July 13, aged 72, of diabetes mellitus.

Bryan Sharkey, Dayton, Ohio; Miami Medical College, Cincinnati, 1902; for many years practiced in Middletown, where he served as chairman of the board of health and on the staff of Middletown Hospital; died July 16, aged 74, of cerebral hemorrhage.

Russell Aber Shirrefs ⊕ Elizabeth, N. J.; Columbia University College of Physicians and Surgeons, New York, 1899; formerly county coroner; on the staffs of Elizabeth General and St. Elizabeth's hospitals; died July 15, aged 73, of carcinoma of the stomach.

James Ernest L. Spalding, Muncy, Pa.; Hahnemann Medical College and Hospital of Philadelphia, 1928; member of the American Medical Association; served as president of the local board of health; affiliated with the Muncy Valley Hospital; died July 17, aged 45, of coronary thrombosis.

Newton C. Speer ⊕ Kansas City, Kan.; Kansas City (Mo.) Medical College, 1900; at one time practiced in Osawatomie, Kan., where he was on the staff of the State Hospital and division surgeon for the Missouri Pacific Lines; later industrial surgeon and Kansas City, Mo., terminal surgeon; on the staffs of Bethany, St. Margaret's and Providence hospitals in Kansas City, Kan., and St. Vincent's Hospital in Kansas City, Mo.; killed near Peculiar, July 6, aged 71, when his automobile collided with a bus.

William August Steffen ⊕ Sheridan, Wyo.; Illinois Medical College, Chicago, 1904; served as president of the Wyoming State Medical Society and the state board of medical examiners; served during World War I; died July 12, aged 68, as the result of injuries received in a fall.

J. Carl Steiner ⊕ Quincy, Ill.; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1907; on the staff of the Blessing Hospital, where he died July 9, aged 64, of heart disease.

Margaret Ann Hutchinson Sutley ⊕ Philadelphia; University of Colorado School of Medicine, Denver, 1918; fellow of the American College of Surgeons; on the staff of the Woman's Hospital; died July 17, aged 53, of carcinoma of the breast.

Stephen Dana Sutliff ⊕ Shippensburg, Pa.; College of Physicians and Surgeons, Baltimore, 1901; physician for the board of health; on the staffs of the Carlisle (Pa.) Hospital and the Chambersburg (Pa.) Hospital, where he died July 16, aged 69, of injuries received in an automobile accident.

William Jasper Sweeney, Liberty, Ky.; University of Louisville Medical Department, 1909; died July 7, aged 62, of Hodgkin's disease.

John Samuel Taylor, Richland, Wash.; University of Pennsylvania School of Medicine, Philadelphia, 1938; member of the American Medical Association and the Medical Association of Puerto Rico; on the staff of the Kadlec Hospital; drowned July 9, aged 34, while attempting to save another swimmer at Long Beach.

John Young Templeton ⊕ Mooresville, N. C.; Jefferson Medical College of Philadelphia, 1913; died July 15, aged 59, of coronary thrombosis.

Frank Edward Tull, Fontana, Calif.; Rush Medical College, Chicago, 1891; died July 16, aged 82, of cerebral hemorrhage.

KILLED IN ACTION

Stanley Joel Snitow, New York; Cornell University Medical College, New York, 1940; diplomate of the National Board of Medical Examiners; interned at the Mount Sinai and the New York hospitals; began active duty as a first lieutenant in the medical corps, Army of the United States, attached to the Air Corps, on Nov. 26, 1942; during his period of training in various stations in this country served as an aviation examiner; promoted to captain; in the early part of April 1944 left the United States for overseas duty as a flight surgeon; awarded posthumously the Purple Heart, the Congressional Medal of Honor and a citation from the late President Roosevelt; killed in the North African area April 20, 1944, aged 27, when the ship on which he was being transported was torpedoed by the Germans during an aerial attack.

State Medicine in Practice

Sir Ernest Graham-Little, dermatologist, member of Parliament and well known as a writer on medical politics, shows in the *Daily Telegraph* the results of a state medical service in New Zealand, where it was instituted by the labor government and has been in operation for ten years. Since the war the system has been fully reviewed in the House of Representatives, and almost universal dissatisfaction with it has been expressed. The complaint was made that it is a common practice for physicians operating the health services to undertake treatment of an impossible number of patients and to push them through at the rate of 1 every five minutes. If the diagnosis is not conclusive the patients are sent to the public hospitals, which are consequently filled with trivial cases, crowding out serious cases. The prime minister, who had a large part in founding the scheme, was so shaken by the evidence that he said: "If patients are being treated like sheep passing through a dip, without proper overhaul, the matter should be investigated." In a subsequent debate the minister of health admitted that the abuses of the system were such that the government must seriously consider altering it.

Other criticisms have been made. For instance it is contended that while state doctors draw extravagant incomes from the social security fund, it is extremely difficult to secure any medical attention outside business hours or during the week end. There is said to be a definite falling off in the standard of medical practice, from both the ethical and the clinical points of view. The absence of incentive to undertake the prolonged training to qualify for the status of specialist has resulted in a serious dearth of skilled physicians and surgeons and consequent discouragement of both medical research and postgraduate study.

The cost of the security benefits has mounted sharply. During the year ending March 1 it was $139,000,000 against $83,000,000 for the previous year. The drug bill increased from $2,250,000 in 1943 to $5,700,000 in 1947 and the medical benefits from $4,000,000 to $7,000,000 in the same period.

The Healthiest Year Known

During the war it was frequently noted that the vital statistics showed an improvement on those of peacetime. The Registrar-General's statistical review for England and Wales, which has just been published, shows that 1945 was the healthiest year ever known. It also discloses that the majority of civilian war deaths in that year were caused by rockets and to a limited extent by a new series of flying bomb attacks launched from bases in the Netherlands. The total number of deaths was 488,108, giving a crude death rate of 12.6 per thousand civilian population—lower than the rates of 12.7 and 13 for the two previous years, but 1 above the rate for 1938. But the comparative mortality index, which allows for the changing sex and age structure of the population and expresses the mortality of each year as a ratio to that of 1938, was only 0.893, which makes 1945 the healthiest year on record. The infant mortality rate, after reaching a new low record of 45.44 per thousand live births in 1944, rose very slightly to 46 in 1945 but maintained the improvement shown during the war. Maternal mortality (excluding abortion) continued to diminish steadily, reaching 1.52 per thousand births in 1944 and 1.47 in 1945. As a result of the immunization campaign only 694 deaths were attributed to diphtheria in 1945, and the death rate for children under 15 years of age reached a new low level of 57 per million.

The Result of the Trials of Streptomycin

The Ministry of Health announces that the preliminary results of the trials of streptomycin in this country encourage the view that, as available supplies of the drug permit, patients suffering from tuberculous meningitis or miliary tuberculosis should be given the opportunity of receiving treatment with the drug. While streptomycin is the best drug available for the treatment of these conditions, it prolongs life and relieves symptoms in only a proportion of cases. It is too early to say whether it ever produces a permanent cure.

The production of streptomycin in this country is still limited, but additional supplies obtained from the United States have enabled arrangements to be made for a certain number of medical schools to receive an allocation each month for use in teaching and associated hospitals. The number of beds for which supplies are available is about one hundred and fifty. The cost of streptomycin is still extremely high, and for the time the supplies are being distributed by the government to the medical schools free of charge. In view of the limited experience with streptomycin in the treatment of other conditions, the medical schools have been asked for the present to restrict use of the drug to cases of tuberculous meningitis and miliary tuberculosis. It is not recommended for use in chronic pulmonary tuberculosis.

Control of the Sale and Use of Penicillin and Streptomycin

A bill to control the sale and use of penicillin and other substances has passed through the House of Commons. The minister of health, Mr. Bevan, explained the dangers of unrestricted sale. Penicillin taken over a long period in small quantities establishes in the organism a resistance to its beneficial effects. It is highly undesirable that this valuable substance should become the plaything of quacks, sold as penicillin lipstick, penicillin rouge and penicillin powder. The bill laid down that penicillin could be given only on the certificate of a qualified medical practitioner or veterinary surgeon.

The bill also took power to deal with other drugs where control might later be found necessary. One called streptomycin had given Mr. Bevan considerable trouble. Great expectations had been carelessly aroused about it, but the Ministry of Health knew that this drug had caused definite harm. In other instances, although a healing effect had been claimed, that had not been established. Investigations were proceeding, which, if they proved successful, would transform the whole field of medicine, but the government was anxious that when these were perfected it would have power to prevent their thoughtless consumption and commercial exploitation in an injurious manner. Therefore the bill controls these substances.

Institute of Animal Physiology to Be Set Up

The Agricultural Research Council has decided, after a careful review, that in many directions progress toward the improvement of animal health and production is restricted by lack of knowledge of the fundamental physiology of farm animals. To fill in some of the gaps in knowledge a new Institute of Animal Physiology is needed, and the Ministry of Agriculture has decided to establish this. The director will be Professor I. de Burgh Daly, who is professor of physiology in Edinburgh University. It is hoped that he will take office early in 1948. The council proposes to appoint as his senior colleagues two scientific workers of high distinction in biochemistry and pathology.

Dr. S. H. Daukes an Organizer of Museums

The death at the age of 68 of Dr. S. H. Daukes has removed a great organizer of museums. He served with distinction in World War I as divisional sanitary officer. His interest in museums and graphic methods of medical education began when he was appointed to organize the War Office School of Military Hygiene. He contributed the chapter on Hygiene to the official Medical History of the War. The late Sir Andrew Balfour, director of the Wellcome Research Institute, was so struck with his work on public health that he invited Daukes to take charge of the Wellcome Museum of Medical Science. In 1923 Daukes advocated the institution of a museum of wider scope to illustrate the latest knowledge concerning diseases and hygiene and to show the steps by which this knowledge had been reached. His plan was warmly approved by Sir Henry Wellcome, and in 1926 the Wellcome Museum of Medical Science was opened with Daukes as its first director. Under his direction the museum played an important part in organizing exhibitions at home and abroad. It set new standards in visual education and increased the prestige of British medical science. He displayed his wide knowledge and enthusiasm for the modern museum as an educational method in his monograph, "The Medical Museum" (1929). In addition to these activities he distinguished himself in general literature. He was a successful novelist, and one of his books, "The Doctor's Defence," was a best seller. Others were "A Cuckoo in Harley Street" and "He Loved Freedom." In the last, which was published a few days before his death, he dealt with the reactions of the physician to state medicine: "He sits at a big desk surrounded by Government forms and little rubber stamps."

Medical Education in Germany

The universities are greatly hampered in their activities by the destruction of many of their buildings, institutes, clinics and laboratories. As compared with twenty-three universities in 1932, there are twenty-two now. The universities of Breslau and Königsberg (both cities under Polish administration) have ceased to operate, while the French have opened a new university at Mainz, and plans are under way for another one in the Saar. Except for Giessen, all universities have medical faculties.

The biggest shortage is in textbooks; most public and private libraries and many bookstores have been destroyed by acts of warfare, and new textbooks have not yet been published. Textbooks are often of a generation ago, and even these are scarce.

Another great difficulty is housing. Mainz University has introduced the American type of campus life (dormitories and boarding). All other universities are lacking such facilities, which are contrary to the old German students' tradition.

The field of university studies which most students desire to take up is medicine, especially so in the American and Russian zones of occupation. At present, many universities do not admit first year medical students.

The number of registered medical students in the four zones is as follows: American, 10,714; British, 6,430; French, 2,887, and Russion, 3,336 plus an unknown number from Rostock and Greifswald which do not give official figures.

The social structure of the student body has changed, particularly in the Russian zone. Almost all universities have introduced a numerus clausus, a novel feature in Germany where universities have always been state-owned and open to all who could meet scholastic requirements. Now, more students are refused than admitted; but the highest percentage of refusals occurs in the Russian zone, where a strong tendency prevails to increase the number of students who come from the working class. Thus, 24 per cent of the students at the Russian-controlled Berlin University were admitted without having graduated from "Gymnas-ium," the German equivalent of high-school plus precollege education. As yet, however, less than 10 per cent of the members of the student body are sons and daughters of workers. Not much change in the social structure of the student body has occurred in the Western zones, except for the general lowering of the standard of living.

The percentage of women students is higher in the Russian zone than in Western Germany. In Berlin, for example, women constitute 40 per cent of the total, with an absolute majority at the Medical and Philosophical Faculties. In 1932 only one fourth of the students were women.

The location of the universities presently in operation in the four zones of Germany is as follows:

American	British	French	Russian
Erlangen	Bonn	Freiburg	Berlin
Frankfurt	Göttingen	Mainz	Greifswald
Heidelberg	Hamburg	Tübingen	Halle
Munich	Kiel		Jena
Marburg	Cologne		Leipzig
Würzburg	Münster		Rostock
Giessen (no medical faculty)			

Medical Literature and the Study of Medicine in Germany Today

There is a great revival of medical periodical literature in Germany today, particularly when compared with the low level of economic life. All publishers need licenses by the information control divisions of military government. Such licenses have been issued in considerable numbers by the four occupying powers to medical publishers free from Nazi taint.

In the field of general medicine, the four best known weeklies are published again regularly:

Aerztliche Wochenschrift (Springer, Berlin and Heidelberg)
Klinische Wochenschrift (Springer)
Medizinische Klinik (Urban & Schwarzenberg, Berlin, Munich and Vienna)
Deutsche Medizinische Wochenschrift (Thieme, Stuttgart)

Other periodicals in the field of general medicine are:

Therapie der Gegenwart (Urban & Schwarzenberg)
Medizinische Monatsschrift (Wissenschaftliche Verlagsgesellschaft Stuttgart)
Aerztliche Forschung (Werkverlag Dr. Banaschewski, Bad Wörrishofen, Bavaria)
Medizinische Rundschau (own publishing house in Mainz, French zone)
Das deutsche Gesundheitswesen (published by the "German Central Administration of Public Health in the Soviet zone of occupation" and printed in Berlin through the "Cooperative of German Medical Publishing Houses").

In the various specialties the following periodicals are published:

Surgery:
  Der Chirurg (Springer, monthly)
  Zentralblatt für Chirurgie (Thieme, Leipzig)
  Zeitschrift für Orthopädie und ihre Grenzgebiete (Ferdinand Enke, Stuttgart)

Dermatology and Syphilis:
  Archiv für Dermatologie und Syphilis (Springer)
  Zeitschrift für Haut- und Geschlechtskrankheiten und deren Grenzgebiete (Berliner Medizinische Verlagsanstalt, biweekly)
  Dermatologische Wochenschrift (Barth, Leipzig, weekly)

[illegible] monthly)
[illegible] *[illegible]ervenheilkunde* (Springer)

Gynecology and Obstetrics:
  Zeitschrift für Geburtshulfe und Gynäkologie (Ferdinand Enke, Stuttgart)
  Zentralblatt für Gynäkologie (Thieme, Leipzig)

Anatomy, Physiology, Pathology, Biochemistry:
  Biochemische Zeitschrift (Springer)
  Virchow's Archiv für pathologische Anatomie und Physiologie und für klinische Medizin (Springer)
  Pflüger's Archiv für die gesamte Physiologie des Menschen und der Tiere (Springer)
  Naunyn-Schmiedebergs Archiv für experimentelle Pathologie und Pharmakologie (Springer)

Pediatrics:
  Archiv für Kinderheilkunde (Ferdinand Enke, Stuttgart)

[illegible]
  [illegible] *für Augenheilkunde und für Augenarztliche* [illegible] Enke, Stuttgart)

Tuberculosis:
  Der Tuberkuloseartzt (Thieme, Stuttgart)

Internal Medicine:
  Zeitschrift für die gesamte innere Medizin und ihre Grenzgebiete (Thieme, Leipzig)

Urology:
  Zeitschrift für Urologie (Thieme, Leipzig)

Radiology:
  Die Strahlentherapie (Urban & Schwarzenberg, Berlin)

Psychology:
  Psyche (Lambert Schneider, Heidelberg)

About twenty more formerly well known periodicals are scheduled to come out soon. Their publication has been delayed by the acute shortage of paper and by other technical difficulties.

OSLO

(From Our Regular Correspondent)

Sept. 8, 1947.

Troublesome Taxation

Of late the fiscal authorities seem to have turned a grudging and jaundiced eye on us doctors. For how otherwise can we explain two recent fiscal rebuffs. The first concerns taxation of motor cars. In 1917 a luxury tax was put on motor cars, but physicians could on application obtain relief from it. This concession was withdrawn in 1933, presumably because it had been abused. Time and again the Norwegian Medical Association sought relief from this tax for those of its members whose motor cars were used in their practices. In 1946 the fiscal authorities made this luxury tax heavier than ever, and again the physicians protested. To be sure, the fiscal authorities flirted for a moment with the idea of a concession to physicians, but the latest plan for taxation for the fiscal year 1947-1948 shows no sign of relenting on the part of the government. Our other grievance concerns a scheme for pensions for doctors who are not in the public health service. The Norwegian Medical Association has recently weighed the possibilities of a scheme of voluntary contributions to a pension fund, physicians to earn their pensions by annual contributions to be exempt from income tax. To which the fiscal authorities have, in effect, replied: Whatever sum above 300 kroners a year is paid into a pension fund is not to be exempt from taxation. And it is largely on account of this ruling that this proposed scheme hangs fire.

Norway's Unacknowledged Contributions to Medicine

When Norwegians travel abroad they often find to their dismay that their most distinguished compatriots are unknown or (what is still more galling) are supposed to be Swedes or Danes. It may be too late in the day to teach their foreign colleagues elementary geography and to disentangle Oslo, the capital of Norway, from the suburbs of Stockholm or Copenhagen. One of the nation's coming men, Professor Axel Ström, returned last year from a visit to the United States with the suggestion that Norwegian physicians could better hold their own in the international world of medicine if they systematically sent to all the most important libraries in the world copies of their original contributions to medicine, such as theses for the degree of M.D. This will cost a great deal. But it may also mean that credit will be given where credit is due and it may save their colleagues abroad from the invidious achievement of duplicating old discoveries hitherto overlooked.

The Future of Fat Children

What was the ultimate fate of the fat boy in "Pickwick Papers"? As Dickens assuredly drew him from life, it should have been possible to learn what became of him. At present not much is really known on this score, most research with regard to the prognosis for adiposity having dealt with persons over the age of 20. The omission is curious, for there must be thousands of anxious parents wanting to know whether their overweight offspring will continue to bulge unesthetically in adult life. Recently Dr. Per Hanssen has dealt with this problem in some detail in connection with 5 cases. Another Norwegian, Dr. Carsten Müller, has carried out a follow-up study of 20 overweight youngsters between the ages of 10 and 20 years and has found that they show a reassuring general tendency to regain normal dimensions on and after coming to years of discretion.

Centralized or Decentralized Libraries

In Oslo many of the medical journals subscribed to from public funds are scattered throughout various hospital departments, journals devoted to venereal disease, for example, being allocated to a dermatologic department, journals on surgery to a surgical department and so on. The severity or laxity with which these departments treat long-fingered would-be borrowers of medical literature reminds one of the tale of the possessor of a large library who, when asked how he dealt with books lost, stolen or strayed, confessed that all his books had been borrowed. The *Journal of the Norwegian Medical Association* has lately put forward a plea on behalf of the research workers who are obliged to go from one building to another in search of the books and journals they need. The solution proposed is, of course, centralization. In theory this solution is excellent. The full-time librarian is a much more effective custodian of reading matter than a score of part-time workers, each with his own system or lack of system in lending books. But in practice the change-over from the present state of affairs to complete centralization may prove rather difficult.

Professor Theodor Frölich

After a long and painful illness, Professor Theodor Frölich died August 14 at the age of 76. He was professor of pediatrics at the University of Oslo till he reached the age limit in 1940. The work which gave him an international reputation at the beginning of this century was carried out in conjunction with Professor Axel Holst, with whom he studied experimental scurvy in guinea pigs. Their first publication on this subject appeared in 1907 at a time when the knowledge of vitamins was infinitesimal. Indeed, the claim may safely be made that the investigations of Holst and Frölich constitute the most important foundation of present knowledge of vitamin C (ascorbic acid). Frölich was also a pioneer in the field of tuberculosis, and it was he who introduced the wholesale examination of school children in Norway with tuberculin. From 1928 to 1937 he was president of the Norwegian National Association Against Tuberculosis, and in 1930 he presided in Oslo over the Congress of the International Union Against Tuberculosis.

ITALY

(From Our Regular Correspondent)

Naples, July 31, 1947.

A "Rebellion" of Cancer Patients

Quite a stir has been caused during the last few months in connection with a new treatment for cancer. The new preparation, called FA 2 by its originator, is an extract of sheep's liver in high concentration, which produces fever and particularly affects the toxic-encephalic type of patient (in whom there is pronounced anxiety or transient psychosis). The product is claimed to have a sedative effect on pain and to cause a modification of the tumor, which after treatment tends to encroach less on the organ it affects and, according to some, diminishes in size.

The Psychotherapeutic Value

Long and imposing articles have appeared in the press and numerous medical authorities have been consulted for their opinions. The inventor of the preparation, a pharmaceutical chemist of Rome, heretofore not very well known here, has found himself much in the limelight.

The government has been inundated with thousands of letters requesting authorization to sell the drug in pharmacies. Following an investigation into the matter by a specially appointed commission, the Ministry of Health authorized the sale of the new medicament. In doing so the official government report published in the newspapers stated that the drug was none other than a hepatic extract of sheep's liver in high concentration; it was not a dangerous drug and its anodyne action had been determined to a certain extent, but it had no therapeutic effect on the course of the cancer. Many conferences and much planning of research followed this announcement by physicians. As soon as the patients and their families found that nothing prevented them from obtaining the preparation from the pharmacies, nobody wanted any, and a wave of skepticism has emerged during the last few weeks.

Correspondence

MINIMAL PATHOLOGY COMMITTEE

To the Editor:—In the face of recent statements in the press regarding unnecessary operations, it might be of interest to other hospitals, as well as to the members of the profession at large, to learn of what has come to be known at this hospital (Mary Immaculate Hospital) as the "minimal pathology committee."

This is a standing committee, appointed within the past year by the medical board and composed of five members representing the general surgical service, including gynecology, the urologic service and the department of pathology.

The purpose of this committee is to discourage the carrying out of operative procedures for which the indications are not sufficiently clear or the existing pathology adequate to justify them; in other words, to prevent unnecessary operations.

The committee examines all surgical specimens in which a minimal pathologic state is thought to exist and in addition reviews the corresponding charts for data concerning the need for the operative undertaking. If, after this has been done, the committee is not convinced of the justification for surgical intervention, it next decides to interview the surgeon concerned, whose name is then, for the first time, disclosed. In this way further information may be obtained of such a nature as to satisfy the committee, the case then being closed. If not, whatever action seems appropriate is carried out through the proper authorities, even if this means the curtailment or complete withdrawal of surgical privileges at the hospital.

The benefits derived from the activities of this committee are quite definite. In the first place it is obvious that with the knowledge on the part of the professional staff that such a committee exists, additional concern is bound to be felt by every surgeon, even the most conscientious, that the disease processes found in his patients and revealed in the specimens sent to the laboratory shall be adequate to justify his operative procedures. The staff member becomes still more "pathology conscious," weighs even more carefully the existing indications and is more than ever cautious about performing an operation which may later be adjudged to have been unnecessary. It is therefore apparent that if there are any on the staff who habitually exercise poor surgical judgment or, perhaps, demonstrate a dulled sense of what constitutes sound professional conduct, the means for the detection of such men and for weeding them out from the staff are to be found in the workings of this committee.

On the other hand, the favorably expressed judgment of the committee, after a thorough investigation of any doubtful case, might well prove of value, legally or otherwise, to the surgeon concerned, when, despite a conscientious approach, the pathologic condition found proved after all that the operation was unnecessary. Such, for instance, was the case of a nephrectomy for a supposed, though nonexistent, tumor of the kidney. Investigation of this case resulted in the approval by the committee of the action taken by the surgeon concerned, for it became obvious, on interview, that every effort had been made to reach a sound conclusion. The member of the committee representing urology willingly admitted that in view of the facts available, had the case been his, he would have felt compelled to carry out the same procedure.

An indirect benefit which may be looked for in connection with the functioning of a "minimal pathology committee" is increased attention to clinical records. Aware of the possibility of review in any borderline case, a surgeon will be more apt to include in the record every fact or observation which has a bearing on the need for surgical intervention.

Such a committee, then, functioning impersonally, may well act as a safeguard for the patient, minimizing as it will the possibility of his undergoing an unnecessary operation. It may be a safeguard for the surgeon as well, who in a doubtful case may, under certain circumstances, find the support of the committee a valuable asset. Finally it may serve as a safeguard for the interests of the hospital, with its primary concern for the care of its patients, for the caliber (ethical and professional) of the physician on its staff and for its own reputation in the community.

Mary Immaculate Hospital,
Jamaica, N. Y.

THE WORD "TOOL" IN MEDICAL WRITING

To the Editor:—Is it not important that something be done to discourage use of the word "tool" to describe a drug or other nonmechanical method for the treatment of human illness? The custom has grown so steadily that now no physician seems to consider his manuscript up-to-date if he does not use (or misuse) the word "tool" at least once in each article or in discussion.

And now the press has done it! In the Sept. 12, 1947 issue of the previously staid and correct *New York Times* the following sentence appeared on page 23: "An anesthetic called procaine, injected into the human blood stream to relieve the symptoms of certain diseases such as arthritis, which can be reached only by venous routes, was described yesterday at the final session of the Congress of Anesthetists in the Hotel McAlpin as a promising tool for medical use."

Is procaine a tool? Is it an implement, especially for manual use, as a hammer or saw, or a person or thing used as an agent or instrument as the "tool of a stronger nature," or an apparatus, device or utensil? Those seem to be the meaning of the word as found in the average dictionary. Funk and Wagnall's dictionary does state, however, that another use of the term is "both contrived and used for extending the force of an intelligent agent." Perhaps this definition justifies in some degree the growing present day use of the word, but I am inclined to doubt it. Physicians, anthropologists, psychologists and others of higher learning apparently think that a tool is anything which they want to so designate. The psychiatrist finds intravenous "sodium amytal" "a useful tool" in diagnosis and treatment, or considers hypnosis "a useful tool." If archaeologists or anthropologists meant a pick or shovel which they use for digging, one could understand their meaning readily; but they too find equally abstract methods or ideas "useful tools."

Harold J. Harris, M.D., New York.

URETHANE IN ANAPLASTIC CARCINOMA

To the Editor:—Following the report of the use of urethane in a patient with anaplastic carcinoma by Drs. M. J. Goodman and H. P. Lewis (J. A. M. A., Correspondence, **132**:1105 [Dec. 28] 1946) a justifiable opportunity for therapeutic trial of this material presented itself in a similar case. A man aged 34, who had served without medical incident throughout the North African, Sicilian and Italian campaigns and whose past history was otherwise noncontributory, was hospitalized for progressive anorexia with loss of weight and unremitting fever. A rectosigmoid peritoneal shelf was palpated, and examination after a barium enema revealed an apparently extrinsic constricting mass in this area. Because of the clinical diagnosis of carcinoma originating in the ailmentary tract with extensive peritoneal metastasis, a laparotomy was forgone. However, biopsy of a "nova" right supraclavicular gland showed infiltration by a distinctly anaplastic epithelium, which the pathologist could not reconcile with other than bronchiogenic origin on a probability basis even though roentgen examination showed the lung fields to be clear.

One gram of urethane in syrup of orange was administered three times a day for a period of three weeks, during which nutritional maintenance was attempted by parenteral amino acid and dextrose therapy. There was no apparent effect on the progression of the disease, and the dosage of urethane was discontinued ten days before the man's death, because of the retching it seemed to induce.

Necropsy revealed universal visceral lymphangial anaplastic carcinomatosis. The rectosigmoid shelf had merely been the palpable manifestation of a panserosclerosis. The porta hepatis had become converted into a solid, impatent cord. Still, no peritoneal transudate was present. The peribronchial and mediastinal lymphatics were everywhere involved as were both parietal and visceral pleuras. No primary site could be determined.

Histologically there was no evidence of tumor cell inhibition. In fact, comparison with the node excised before the inception of urethane therapy indicated, if anything, that after the course of urethane mitotic figures were even more plentiful.

Aside from the accidental similarity of the covert primary lesion, this case probably differs radically from that described by Drs. Goodman and Lewis; the disease was in a terminal state before the administration of urethane was started, and it is entirely possible that there was complete failure of absorption. It is nevertheless believed advisable to report the fact and circumstances of apparent unresponsiveness, so that progress with this new form of therapy may be properly adjudicated.

Robert D. Barnard, M.D., New York.

MODERN GERMAN PANEL PRACTICE

To the Editor:—With the continued agitation for state medicine it might be of interest to show how it works out elsewhere. The following account on panel practice is from a recent letter received from an eye physician in a large city in southern Germany in the American zone of occupation:

"Conditions regarding income from practice were still regular here till the beginning of this year. These have now become catastrophic through restrictions in the panel practice. In the first quarter of 1947 I treated 1,904 panel patients, for which I formerly received a flat rate of about 4 marks; therefore, about 8,000 marks. Now there is staggering in favor of the physicians with a smaller practice, especially the refugee physicians, which is as follows: For the first 500 cases I receive as heretofore 4 marks (2,000 marks); for the sixth, seventh, eighth and ninth hundreds I receive 3.60, 3.00, 2.50 and 0.90 marks (360, 300, 250 and 90 marks) and for the remaining 1,004 cases, 0.60 marks (602.40 marks). For all 1,904 cases, therefore, I receive 3,602.40 marks.

"My expenses during the quarter are a little over 3,000 marks, so that they almost equal the income from the panel practice. Under these circumstances I would have the greatest interest to reduce my panel practice two thirds to three fourths (so I would treat only 500 panel patients). I would then still earn 2,000 marks from my panel practice, but my expenses would be much lower, for I would be able to discharge one office worker, who receives 750 marks for the quarter. My net income from panel practice would then, when I treat only 500 panel patients, be relatively higher than when I treat three to four times as many. This will be astonishing to you, but it is a fact. But I am not allowed to curtail my panel practice arbitrarily, for according to the edicts about settlement, which have just been revised, I am entitled and *obliged* to treat private and panel patients. I am really not permitted to turn down panel patients. So done in the year 1947. Do they call that democracy in America? Now I have, thank God, a rather large private practice on the side, which covers the deficit and allows my subsistence."

Hans Schroeder, M.D., San Francisco.

Medical Motion Pictures

FILM REVIEWS

Gelatin Sponge ("Gelfoam") for Control of Hemorrhage. 16 mm., color, silent, 1,300 feet (1 reel), showing time forty-seven minutes. Produced by Hilger Perry Jenkins, M.D.; Robert W. Jampolis, M.D.; Edward Senz, M.D.; Howard Owen, M.D.; Rudolph Janda, M.D., and James Clarke, M.D., Department of Surgery, University of Chicago School of Medicine. Procurable on loan from Hilger Perry Jenkins, M.D., 826 East Sixty-First Street, Woodlawn Clinic Building, Chicago.

This motion picture presents an experimental study in dogs on the use of absorbable gelatin sponge ("gelfoam") for the control of hemorrhage. It covers a description of the character of the material; demonstrations of the technic of its application to various types of wounds in animals; gross and microscopic illustrations of what becomes of the sponge and its effect on the subjacent tissues of animals.

The film is a well balanced presentation of the experimental use of gelatin sponge in that the existence of the competing materials, fibrin foam and oxidized cellulose, is mentioned at the beginning and that its limitations are emphasized at the end. Another important point, that the "know-how" in technic must be gained by actual experience, is also adequately stressed. The demonstrations of the blanket technic for the liver; the patch technic for stab wounds of the vena cava and the heart, and the cuff technic for the aorta are exceptionally clear. The illustrations of the adherent clotting mechanism involved are also well done. Some of the photomicrographs of tissue sections are hazy and will be less readily understood by those not having special training in micropathology. Part of this might have been obviated by more detailed explanation of the tissue changes, and the use of markers to indicate the exact area under illustration. One other defect in the film lies in the lack of more adequate explanation for the failures that occurred in the series of animals studied. The photomicrographs are rather poor; otherwise the photography is good.

This motion picture should be of primary interest to general surgeons interested in a method for the control of hemorrhage that cannot be managed by ligatures and sutures and to specialists in vascular surgery, in which the gelatin sponge may serve as an adjunct to the use of other materials. Fourth year medical students, hospital interns and residents that have had at least some first hand observation of surgical technic may also find the film instructive.

To Hear Again. 16 mm., black and white, sound, 1,300 feet (1 reel), showing time thirty-seven minutes. Produced in 1947 by the Medical Department, U. S. Army. Procurable on loan from Office of the Surgeon General, U. S. Army, Pentagon Building, Washington, D. C. Attention: Chief of the Division of Education and Training.

This film shows a series of episodes in an Army Rehabilitation Center which illustrate some general principles in the rehabilitation of men and women with impaired hearing.

The portrayal is vivid and convincing; not a single unrealistic detail intrudes. There is a portrayal of the diagnostic procedure for distinguishing psychogenic from organic impairment, of the selection of hearing aids for those requiring them, of the teaching of lip reading, of the correction of speech difficulties and even of the psychotherapy used in a patient with hysterical deafness. The last-named episode is an outstanding performance showing how scientific accuracy can be combined with artistic quality.

If the film has a weakness, it lies in the inadequate suggestion of what constitutes a satisfactory adjustment to civilian life. Considerable attention is given at the end of the film to a dance at which soldiers who wear hearing aids are enjoying the performance of a swing band. It arouses the hope that something more useful is in prospect for these men. The film should be interesting to everyone connected with rehabilitation problems; to students in medicine, nursing, speech and psychology who may require a review of the general problem of audiometry and hearing aids, and to groups working with patients who present difficulties in hearing and speech. The photography, narration and general over-all treatment are excellent.

Medical Examinations and Licensure

COMING EXAMINATIONS AND MEETINGS

NATIONAL BOARD OF MEDICAL EXAMINERS EXAMINING BOARDS IN SPECIALTIES

Examinations of the National Board of Medical Examiners and the Examining Boards in Specialties were published in The Journal, Oct. 11, page 376.

BOARDS OF MEDICAL EXAMINERS

Alabama: *Examination.* Montgomery, June 22-24, 1948. Sec., Dr. D. G. Gill, 519 Dexter Ave., Montgomery 4.

Arkansas:* *Examination.* Texarkana, Nov. 6-7, 1947. Sec., L. J. Kosminsky. Texarkana. *Eclectic.* Little Rock, Nov. 6. Sec., Dr. Clarence H. Young, 1415 Main St., Little Rock.

California: *Written.* Sacramento, Oct. 20-23. *Oral.* Los Angeles, Nov. 8-9. Sec., Dr. Frederick N. Scatena, 1020 N St., Sacramento 14.

Colorado:* Denver, Jan. 6-9. Final date for filing application is Dec. 20. Sec., Dr. J. B. Davis, 831 Republic Bldg., Denver 2.

Connecticut:* *Examination.* Hartford, Nov. 11-12. Sec., Dr. Creighton Barker, 258 Church St., New Haven.

Delaware: *Examination.* Dover, Jan. 13-15. *Endorsement.* Dover, Jan. 20. Sec., Dr. J. S. McDaniel, 229 S. State St., Dover.

District of Columbia:* *Examination.* Washington, Nov. 10-11. Sec., Commission on Licensure, Dr. G. C. Ruhland, 6012 Municipal Bldg., Washington.

Florida:* *Examination.* Jacksonville, Nov. 25-26. Sec., Dr. Harold D. Van Schaick, 6675 Windsor Lane, La Gorce Island, Miami.

Hawaii: *Examination.* Honolulu, Jan. 12-15, 1948. Sec., Dr. S. E. Doolittle, 881 S. Hotel St., Honolulu, T. H.

Idaho: Boise, Jan. 13-15. Sec., Miss Estella S. Mulliner, 355 State Capitol Bldg., Boise.

Indiana: *Examination.* Indianapolis, June 1948. Sec., Board of Medical Registration and Examination, Dr. Paul R. Tindall, K of P Bldg., Indianapolis.

Kansas: Topeka, Dec. 3-4. Sec., Board of Medical Registration and Examination, Dr. J F. Hassig, 905 N. 7th St., Kansas City.

Maine: Portland, Nov. 12-13. Sec., Dr. A. P. Leighton, 192 State Street, Portland.

Maryland: *Medical Examination.* Baltimore, Dec. 9-12. Sec., Dr. Lewis P. Gundry, 1215 Cathedral St., Baltimore. *Homeopathic Examination.* Baltimore, Dec. 9-10. Sec., Dr. J. A. Evans, 612 W. 40th St., Baltimore.

Massachusetts: *Examination.* Boston, Nov. 18-21. Sec., Dr. H. Q. Gallupe, 413-E State House, Boston.

Michigan:* *Examination.* Lansing, Nov. 19-21. Sec., Board of Registration in Medicine, Dr. J. E. McIntyre, 100 W. Allegan St., Lansing 8.

Minnesota:* Minneapolis, Oct. 21-23. Sec., Dr. J. F. DuBois, 230 Lowry Medical Arts Bldg., St. Paul 2.

Mississippi: *Endorsement.* Jackson, Dec. 1947. Asst. Sec., State Board of Health, Dr. R. N. Whitfield, Jackson.

Missouri: *Examination.* St. Louis, Oct. 20-22. Exec. Sec., Mr. John A. Hailey, State Capitol Bldg., Jefferson City.

Nebraska:* *Examination.* Omaha, Dec. Dir., Bureau of Examining Boards, Mr. Oscar F. Humble, 1009 State Capitol Bldg., Lincoln.

Nevada: Carson City, Nov. 3. Sec., Dr. G. H. Ross, 215 N. Carson St., Carson City.

New Hampshire: *Examination.* Concord, March 11-12. Sec., Board of Registration in Medicine, Dr. John S. Wheeler, 107 State House, Concord.

New Jersey: *Examination.* Trenton, Oct. 21-22. Sec., Dr. E. S. Hallinger, 28 W. State St., Trenton.

New York: *Examination.* Albany, Buffalo, New York, Syracuse, Feb. 16-19. Sec., Dr. J. L. Lochner, Jr., Education Bldg., Albany.

North Carolina: *Endorsement.* Raleigh, Oct. 20. Act. Sec., Mrs. L. J. McNeill, 226 Hillsboro St., Raleigh.

North Dakota: Grand Forks, Jan. 6-9. Sec., Dr. G. M. Williamson, 4½ S. Third St., Grand Forks.

Ohio: *Examination.* Columbus, Dec. 2-4. *Endorsement.* Columbus, Oct. 14. Sec., Dr. H. M. Platter, 21 W. Broad St., Columbus.

Oklahoma:* *Endorsement.* Oklahoma City, Oct. 28-29. Sec., Dr. F. Clinton Gallaher, 813 Braniff Bldg., Oklahoma City.

Pennsylvania: *Examination.* Harrisburg, Jan. 1948. Acting Sec., Board of Medical Education and Licensure, Mrs. M. G. Steiner, 351 Education Bldg., Harrisburg.

South Carolina: Columbia, Nov. 10-12. Sec., Dr. N. B. Heyward, 1329 Blanding St., Columbia.

South Dakota:* Pierre, Jan. 20. Sec., State Board of Health, Dr. Gilbert Cottam, Capitol Bldg., Pierre.

Texas: San Antonio, Nov. 12-14, 1947. Sec., Dr. T. J. Crowe, 918-20 Texas Bank Bldg., Dallas 2.

Utah: *Reciprocity.* Oct. 8. *Examination.* Salt Lake City, June, 1948. Asst. Dir., Department of Registration, Miss Rena B. Loomis, 324 State Capitol Bldg., Salt Lake City.

Virginia: Richmond, Dec. 4-6. Sec., Dr. K. D. Graves, 30½ Franklin Rd., Roanoke.

Wyoming: *Examination.* Cheyenne, Feb. 2. Sec., Dr. G. M. Anderson, Capitol Bldg., Cheyenne.

---

* Basic Science Certificate required.

BOARDS OF EXAMINERS IN THE BASIC SCIENCES

Arizona: Dec. 16. Sec., Mr. Francis A. Roy, Science Hall, University of Arizona, Tucson.

Colorado: *Examination.* Denver, Dec. 17-18. Sec., Dr. Esther B. Starks, 1459 Ogden St., Denver.

District of Columbia: *Examination.* Washington, Oct. 20-21. Sec., Commission on Licensure, Dr. G. C. Ruhland, 6012 E. Municipal Bldg., Washington.

Iowa: Des Moines, Jan. 13, April 13, July 13, Oct. 12. Sec., Dr. Ben H. Peterson, Coe College, Cedar Rapids.

Michigan: *Examination.* Ann Arbor and Detroit, Jan. 9-10. Sec., Miss Eloise LeBeau, 101 N. Walnut St., Lansing.

New Mexico: *Examination.* Santa Fe, Nov. 2. Sec., Miss Marion M. Rhea, 114 E. Marcy, Santa Fe.

Oklahoma: Spring 1948. Sec., Dr. Frank Clinton Gallaher, 813 Braniff Bldg., Oklahoma City.

Oregon: *Examination.* Portland, Dec. 6. Admin., Mr. C. D. Byrne, Univ. of Oregon, Eugene.

South Dakota: Aberdeen, Dec. 5-6. Sec., Dr. G. M. Evans, Yankton.

Wisconsin: *Examination.* Milwaukee, Dec. 6. Sec., Prof. W. H. Barber, Scott and Watson Sts., Ripon.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Hospitalization Insurance: Failure to Report Operation in Application.—The plaintiff sued for hospital charges and additional miscellaneous benefits under a hospitalization policy issued originally by National Hospital Service Society, Inc., and subsequently assumed by the defendant corporation. From a judgment in favor of the defendant, the plaintiff appealed to the Municipal Court of Appeals for the District of Columbia.

The only issue before the trial court was whether the plaintiff's recovery was barred by her admitted failure to answer correctly certain questions in her application for insurance regarding a previous operation. On such application, which plaintiff filed in April 1941, she was asked whether she had had "medical or surgical treatment or advice in the past ten years." She answered yes and stated that she had had a kidney stone operation in January 1938 and influenza in February 1941. She gave the names of the physicians attending her on those occasions and also gave the name of her family physician. In answer to a further question as to whether she had had any "illness, injury or disability not mentioned previously" she answered "Yes, children's diseases." During her hospitalization in 1945, on which this suit is based, the plaintiff was operated on by Dr. Putski. According to his report he performed, among other procedures, a cauterization of the cervix. In a report which he furnished to the defendant, Dr. Putski, in answer to a question, stated that he had also performed a cauterization of the cervix on the plaintiff in 1939 to cure an ulcerated condition. The defendant rejected the plaintiff's claim for hospitalization benefits for the reason that in her application she had not reported the 1939 cauterization of the cervix.

The only testimony was that of the plaintiff herself and of Dr. Putski. The plaintiff stated that she had not in her application listed Dr. Putski as a physician who had treated her because she "simply did not think of it," that she did not purposely leave out his name, and that she had been referred to Dr. Putski by Dr. Foster, whom she had listed on the application as her family physician. She also testified that the operation in 1939 had been a minor one, that she had had no trouble at all until 1945, and that when she filled out the application in 1941 she was feeling fine; she was in good health until 1945. Dr. Putski testified that his examination in 1939 showed that the plaintiff had an "ulcerative endocervicitis" about the size of a 10 cent piece; he cauterized the cervix under general anesthesia, and the patient had made an uneventful recovery. She was hospitalized in 1945 primarily for the removal of a fibroid of the uterus, a tumor; Dr. Putski said that he also removed her appendix and performed certain other operations as a matter of routine and that he always performs a cauterization of the cervix in connection with such an operative procedure. In his opinion there was no connection between the cauterization of the cervix in 1939 and any of the operations he performed in 1945. On cross-examination the physician testified that a cauterization of the cervix is a minor operation, which he often performs in his office; that in most cases once the cervix is cauterized there is no further trouble, but that in some cases the trouble recurs; that there is nothing serious about a cauterization of the cervix in a normal case, nor is it unusual for a woman to have such an operation more than once.

The court said that to avoid the policy under existing statutes, statements in the application must be both false and made with intent to deceive or material to the risk of its acceptance. Whether a statement is false, made with deceitful intent or material in the statutory sense may be questions of law or of fact depending on the circumstances. It is obvious that a sickness or operation not material under a life insurance policy might be material under a hospitalization policy. In the former case the issue would be whether life was shortened, whereas in the latter the issue would be whether hospitalization would more likely be required. Tested by these principles, said the court, we have concluded that, while we might have found as a fact that the failure to report the 1939 operation was not due to an actual intent to deceive and neither materially affected the acceptance of the risk nor the hazard assumed, yet there was sufficient evidence to justify the trial judge in arriving at the opposite result. Reasonable men might conclude that a person would not forget an operation performed only two years before applying for insurance, particularly when the operation was performed at a hospital under general anesthesia. It is true that the plaintiff reported the kidney stone operation and the attack of influenza, but the trial court could have concluded that she did not want to report too many illnesses for fear the policy would not be written. The physician testified that, in the majority of cases, once the cervix is cauterized there should be no further trouble, but he also testified that in some cases the trouble recurs and that it is not unusual for a female to undergo such an operation more than once. He testified that he cauterized the cervix in 1945 only as a matter of routine, but the fact remains that it was a repeat operation. He testified that he often performed such operations in his office, yet the fact remains that he performed the 1939 one in a hospital. He testified that he considered the 1939 operation only a minor one, yet even a minor operation performed in a hospital may be material to the risk under a hospitalization policy. We find it impossible, the court concluded, to determine as a matter of law that the failure to disclose the earlier operation was immaterial to the hospitalization risk insured against or that plaintiff did not make the misrepresentation with intent to deceive. The judgment in favor of the defendant was accordingly affirmed.—*Turner v. National Hospitalization, Inc., 52 A. (2d) 274 (Dist. of Columbia, 1947).*

Dentists: Right to Restrain Defendant Dental Technicians from Picketing Office.—The plaintiff dentists filed suit for an injunction against the defendant, president of a union of dental technicians, to restrain the union from picketing their private offices. The case was heard on a motion for a temporary injunction in the Supreme Court, special term, Queens County, New York.

The union is composed of dental technicians, whose members are conducting a strike at their employer's plant, H. Brand Laboratories, Inc., which manufactures dentures. The plaintiffs are duly licensed dentists who practice their profession in the same community. No member of the union is employed by any of the plaintiffs; no plaintiff has working for him, as an employee, a dental mechanic or technician or any person doing his work in whole or in part. The union is picketing the places of business of each of the plaintiffs carrying signs which state that the H. Brand Laboratories, Inc., is on strike and that the plaintiffs supply dentures made by the struck laboratory. The factual statement on these signs is true. The plaintiffs insist that they are entitled to an injunction to restrain this picketing because they have no direct relationship with the striking dental technicians and therefore no "labor dispute" exists.

The nature of the relation between the laboratory and the plaintiffs is described as follows: "From time to time a dentist is called on to prepare inlays, bridges, false teeth and the like as a part of his professional service. For this purpose he takes an impression from the mouth of the patient. In order to conserve time, and thereby to meet the needs of all his patients, the dentist sends the impression to a dental laboratory, where a mechanic prepares the inlay, denture or bridge under the direction of the dentist. After the material is prepared from the wax impression, it is returned to the dentist, a fitting is had with the patient, the necessary adjustments are made by the dentist, and the product is then prepared in its final form. The initial preparation of the patient, the removal of the teeth, the taking of impressions, the specification of the type and design of the appliance, and the fitting and adjustment represent the professional skill of the dentist. The cost of the material used is a small part of his charge."

A legal controversy will not be removed from the realm of a "labor dispute," said the court, simply because the plaintiffs and the defendant are not related as employer and employee. If "the case involves persons who are engaged in the same industry, trade, craft or occupation" there is a labor dispute. The plaintiff dentists, the court pointed out, need the services of the technicians properly to provide for their patients. Were the technicians not concentrated in the manufacturer's plant (Brand Company), each plaintiff would have to employ one or more technicians as a part of his office staff and the machinery required to produce dentures would be among his equipment. The mere physical dissociation of the manufacturing of dentures from plaintiffs' offices will not exclude plaintiffs from the "industry, trade, craft or occupation" which uses those dentures for profit. Continuing, the court said that the plaintiff's offices are practically the sales departments for Brand Company. Taking the impression of the patient's gums in his own office the dentist passes that mold on to the manufacturer, who produces the denture. Back to the dentist's office goes the newly created denture for fitting in the patient's mouth. Back to the manufacturer again goes the denture for corrections, and this shuttling is continued until the dentist is satisfied. It is as if Brand Company were the back room or workshop of the dentist's establishment and Brand's employees the plaintiffs' helpers. Were they the plaintiffs' helpers, the work would be done no differently, excepting only the scene of their labors. The plaintiffs and the technicians are engaged in exactly the same occupation. Together they make dentures for particular persons. In this work they are fellow tradesmen. Each completed denture which is accepted and used is an accomplishment in concerted craftsmanship displayed by the plaintiffs and the technicians. It is the result which they hoped for when they essayed together to produce by their talents the exact denture required by the very person for whom it was fashioned. Their alliance in the manufacturing of the dentures is undetachable. Remove one and the effort fails. The way the plaintiffs and Brand Company carry on their business, concluded the court, establishes that "unity of interest" which serves to classify the plaintiffs as persons engaged in the same "industry, trade, craft or occupation" as the technicians and their union. Hence, said the court, this is a "labor dispute" and the complaint must be dismissed. Accordingly judgment was entered in favor of the defendant union.—*Jacobs v. Eisen, 68 N. Y. S. (2d) 921 (New York, 1947).*

Another case involving a different dentist and a different laboratory but the same union and a substantially similar course of conduct was decided just fifteen days later by the Supreme Court, special term, New York County. In that case the judge said: "The complaint does not attempt to comply with Civil Practice Acts, section 876-A and it is conceded that if this is a labor dispute the action and the motion must fail. It is unnecessary to review the relationship of a dentist with his patient and with the laboratory which makes the denture. It has been determined that no relationship of employer and employee nor of producer and consumer is involved and that the picketing under the circumstances constitutes a secondary boycott." The injunction requested by the plaintiff dentist in this case was granted.—*Brennen v. Eisen, 69 New York (2d) 441 (New York, 1947).*

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1937 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied with stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Bacterial Infections During Treatment with Streptomycin or Penicillin.—Alterations in the bacterial flora in various parts of the body may occur in the course of therapy with streptomycin or penicillin, in addition to an effect on the specific organism responsible for an infection. Gram-positive bacteria may be eliminated from the nasopharyngeal flora when penicillin is administered and gram-negative ones when streptomycin is given. In most cases such changes in the bacterial population with suppression of certain groups of bacteria and increase in the number of others probably lead to no untoward result. In other cases such alterations in the flora result in the rapid growth of virulent bacteria, which may have been present originally only in small numbers. The author describes 5 cases of complicating infections occurring in the course of treatment with antibiotic agents, 2 following penicillin therapy and the others following streptomycin treatment. In all of these the second infection was produced by organisms normally present in the nasopharynx. Such development of new infections is a constant danger and must be watched for. The need for intensive bacteriologic study before and during the treatment with antibiotic agents cannot be overemphasized. The use of streptomycin and penicillin simultaneously at the beginning of an infectious disease is not recommended.

Sulfathiazole in Biliary Tract.—Zaslow and Counseller demonstrated the uselessness of penicillin and streptomycin in treating local infection in the presence of acute obstructive cholecystitis. They also found that following oral administration of 3 Gm. of sulfathiazole no drug was present in the bile from the gallbladder when the cystic duct was obstructed. The drug was present in the gallbladder bile when the cystic duct was patent and when the liver excreted it normally. Thus sulfathiazole is likely to be of no value in the treatment of patients with acute obstructive cholecystitis. Acute inflammation of the gallbladder does not alter the mode of entrance of the drug to its lumen. With regard to the hepatic bile, the authors state that after oral ingestion of 3 Gm. of sulfathiazole or intraperitoneal administration of 5 Gm. the drug is excreted in the hepatic bile of normal subjects. The ability of the liver to excrete the drug is impaired in the presence of obstructive jaundice. The greater the degree of hepatic damage, the less is the amount of drug excreted in the bile. Sulfathiazole is likely to prove of no value in the treatment of patients with acute obstructive jaundice with cholangitis. Free drainage of bile must be established if the drug is to be active.

Reiter's Syndrome.—Pinck surmises that Reiter's syndrome is perhaps not as as rare as has been supposed, since he saw 12 cases in the course of two years. It is an unusual disease which is encountered in young males and is characterized by urethritis, conjunctivitis and migratory arthritis. Skin lesions are occasionally noted; these appear as either keratosis blennorrhagica or balanitis circinata. The etiology of the disease is obscure and no definitive therapy is available. The course of the disease is self limited, never terminating, however, in less than three months. Recurrences are not unusual; it may recur years after the initial episode.

Diagnostic Value of Secretin Test.—Lake says that a secretin suitable for intravenous use in man has become available. It is heat stable, free from allergens and cholecystokinin and has caused few untoward reactions. With the use of a specially constructed double barrel gastroduodenal tube and constant suction, Agren and Lagerlöf succeeded in obtaining the duodenal contents uncontaminated by gastric juice. With this technic it became possible to study the effect of a measured dose of secretin on the external secretion of the pancreas. The author presents the results of the secretin test in 18 subjects without pancreatic disease and in 13 subjects with demonstrated disease of the pancreas. The findings agree with those of other investigators and indicate that the secretin test is a valuable diagnostic procedure when extensive structural changes are present in the pancreas. The earliest and most frequent observation is a decrease in diastase secretion. This was usually the only abnormal finding in chronic pancreatitis. A case of extensive carcinoma of the pancreas with functional hyperactivity is reported. A definite response to secretin was demonstrated after removal of approximately five sixths of the organ, the remainder having been implanted into a loop of the jejunum. The composition of pancreatic juice obtained through a fistula was studied before and after the injection of secretin. The composition of this juice was similar to that of the duodenal contents obtained through the swallowed tube following injection of secretin. The external secretory function of the pancreas was studied at intervals after an attack of acute pancreatic necrosis, and the results showed progressive deterioration. The disappearance of bile from the duodenal contents following the *injection of secretin appears to be a reliable indication* of the presence of a normally functioning gallbladder.

Pulmonary Embolism Caused by Penicillin-Oil-Beeswax.—Bondy and his associates report the experience of a Negro woman with cutaneous manifestations of secondary syphilis. She was started on a course of daily injections of 600,000 units of penicillin in oil and beeswax. Eight daily injections were given without difficulty. A few seconds after the ninth injection she complained of a peculiar taste in her mouth. She coughed a few times. After an hour's rest she was sent home. The next morning physical examination of the lungs gave normal results. Since the patient had no fever and felt well she was given the final injection. That afternoon she began to cough again and by evening had developed an uncomfortable shortness of breath. She returned to the clinic and was admitted to the medical ward. At that time her temperature was 103 F., pulse rate 130, respiratory rate 40 and blood pressure 130/70. Her lips and finger nails were cyanotic and there was a pronounced inspiratory nasal flare. Increasing pulmonary changes were noted in the roentgenogram, and pulmonary lipoid embolism was suspected. Animal experiments were done which indicated that the severity of the reaction was due to two factors: (1) the viscosity of the oil-beeswax mixture which caused it to block large branches of the pulmonary artery, and (2) the severe inflammatory reaction elicited by the beeswax. Evidence was obtained which suggested that the severity of the inflammation might have been due to the chemical composition of the wax. The authors emphasize the importance of precaution against intravenous injection of penicillin-oil-beeswax.

Endothelial Cell Sarcoma of Liver After Injection of Thorotrast.—MacMahon and his co-workers report the results of giving thorotrast to visualize the liver. With the aid of this diagnostic procedure, combined with positive serologic tests, it was possible to make an accurate diagnosis of hepatic syphilis with gumma. Following specific therapy, the patient made a clinical recovery and for twelve years lived a reasonably normal life. Death came suddenly at the age of 70. Necropsy confirmed the diagnosis of syphilis and in addition revealed a primary hemorrhagic endothelial cell sarcoma of the liver, the source of fatal hemorrhage, and widespread irradiation injury affecting particularly the liver and hemopoietic system. A study of this case supports the contention that thorotrast in sufficient quantities is injurious as a radioactive substance. Evidence is also produced to show that thorotrast, like other radioactive substances, in sufficient time may act as a sarcogenic agent.

Biologic False Positive Reactions in Syphilis.—Neurath and his associates point out that false positive reactions have been observed in varying intensities and frequencies in apparently healthy persons and in patients with diseases other than syphilis. In syphilis, more than in any other disease, serologic tests play a dominant role in diagnostic procedures. Since in the absence of clinical manifestations or history of syphilis the serologic results must be accepted as the sole criterion for a diagnostic decision, the need for eliminating or recognizing false positive reactions is self evident. While many false positive reactions are of technical origin and may be eliminated by strict adherence to recommended laboratory procedures, others persist even when utmost precautions are observed.

Para-Aminobenzoic Acid in Typhus.—Snyder and his collaborators record experience with para-aminobenzoic acid in treating patients with epidemic louse-borne typhus. They analyze data obtained in 1944 from a series of alternately treated and control patients in Cairo, Egypt, together with data from a similar series observed in 1945. They also describe the treatment of 60 patients in an epidemic of typhus in a concentration camp in Germany and of a miscellaneous group of 5 patients. Analysis of the results in patients treated with para-aminobenzoic acid and in those not treated with this drug reveals significant differences. Treatment with para-aminobenzoic acid is more effective if it is begun early in the first week than if it is begun later. Emphasis is placed on the importance of attaining promptly and maintaining throughout the course of treatment a concentration of the drug in the blood above 10 mg. per hundred cubic centimeters for Rickettsia prowazeki and 35 mg. per hundred cubic centimeters for Rickettsia orientalis. The urine must be kept neutral or alkaline during treatment. The transient lowering of the leukocyte count in some patients was the only evidence of toxic reaction to para-aminobenzoic acid. The pathologic material from 4 fatal cases of typhus treated with para-aminobenzoic acid showed no lesions indicative of poisoning with the drug. One fatal case showed nephrosis of uncertain etiology. Secondary bacterial infections do not preclude the use of para-aminobenzoic acid for rickettsial diseases, but penicillin is advocated as an adjuvant in the presence of secondary infections. Continuance of para-aminobenzoic acid therapy is contraindicated (1) if crystals appear in the urine, (2) if the white blood cell count falls below 3,000 per cubic millimeter and (3) if the polymorphonuclear leukocytes are reduced to less than 25 per cent of the total white blood cell count.

Outbreak of Q Fever at National Institute of Health.—Spicknall and his associates say that at the National Institute of Health, where research was being done on the Rickettsia of Q fever, 18 cases of the fever occurred in an explosive manner between February 6 and February 11. By May 31 the total number reached 47. Pneumonitis was not the predominant clinical characteristic of this outbreak although it was present in 13 of the 45 patients. In many of the patients with pneumonitis the lesions were easily detected by physical signs. Bloody sputum was observed in 5 of these patients. The differential diagnosis may be difficult, but serologic tests are helpful in arriving at a correct diagnosis. Penicillin, sulfadiazine and transfusion of immune blood had no definite effect on the course of the disease.

Four Congenital Cardiac Conditions Causing Cyanosis to Be Differentiated from the Tetralogy of Fallot.—According to Alexander and White, recent surgical advances in the treatment of the tetralogy of Fallot reflect the importance of both the differential diagnosis and the careful selection of suitable cases for surgical treatment. The authors report 4 instances of cyanosis observed at the Massachusetts General Hospital in which the final diagnosis was at variance with that of the tetralogy of Fallot. In each of these the clinical determination of the cardiovascular anomaly before operation would have been of great help to the surgeon, who in each instance followed the Blalock procedure, which consists in anastomosing a suitable vessel of the systemic arterial circulation to the pulmonary artery. Emphasis is placed on the occurrence of tricuspid atresia in a 5½ month old boy in whom periodic attacks of cyanosis were noted by the mother and who showed on physical examination a generalized slate blue color, a grade 4 systolic murmur in the second and third interspaces just to the left of the midsternal line, and a palpable liver. Electrocardiography revealed left axis deviation and x-ray examination showed an enlarged heart without evidence of pulmonary engorgement. A boy aged 5 years with probable Eisenmenger's complex complained of intermittent attacks of shortness of breath and cyanosis. Physical examination disclosed a persistent cyanosis, an enlarged heart, with a grade 2 systolic murmur and a barely palpable liver. X-ray examination of the chest showed pulmonary congestion, and the electrocardiogram showed right axis deviation. The third anomaly consisted of a transposition of the great vessels and was observed in a 17 year old boy who was short of breath, cyanotic and hoarse for the greater part of his life and who had had epistaxis within recent months. Physical examination revealed deep cyanosis, clubbing of the digits and toes and an enlarged heart without murmurs or evidence of pulmonary congestion. X-ray examination suggested the possibility of transposition of the great vessels. Electrocardiography revealed right axis deviation. The fourth patient was that of a boy aged 1 month with a single ventricle. He had periodic episodes of cyanosis and difficulty in breathing. Physical examination revealed moderate dyspnea, cyanosis, an enlarged heart, a grade 3 systolic murmur at the apex and a palpable liver. Right axis deviation was prominent in the electrocardiogram.

Nephrogenic Diabetes Insipidus.—Williams and Henry report observations on 7 members of one family in five generations with symptoms of diabetes insipidus. The disease became apparent soon after birth and occurred only in males but was transmitted only by females. It appeared to be a sex-linked, recessive characteristic. The disease did not respond to pitressin therapy. Neither the serum nor the body cells inactivated pitressin any more rapidly than in normal persons. Since 1 patient reacted to pitressin with generalized blanching and abdominal cramps but not with decreased polyuria, it was concluded that a physiologic and possibly an anatomic defect existed in the kidneys. Renal function tests in this patient showed impairment in the tubular excretion of diodrast and of phenolsulfonphthalein. There was also a decrease in the plasma clearance of urea, sodium, potassium and creatinine. There was a slight decrease in the glomerular filtration and increase in the filtration fraction. The maximal rate of tubular dextrose reabsorption was normal. Intravenously administered sodium chloride was excreted fairly rapidly. It is concluded that there probably is a congenital anomaly of the loop of Henle and the distal convoluted tubules. Although no renal function studies could be made in the other cases, it is assumed that they had the same type of disease. The literature contains no reports of this type of diabetes insipidus.

Streptomycin in Granuloma Inguinale.—Barton and his associates report the results of treatment of 3 patients, all Negroes, 2 women and 1 man, who had evidence of venereal lymphogranuloma. With the recent demonstration of the bacillary nature of the Donovan body it was felt that a study of the effect of an antibiotic on the disease was warranted. Freedom from syphilis, chancroid and lymphogranuloma venereum was established as far as dark field examination, serologic tests, cutaneous tests and clinical examinations were concerned. Donovan bodies were demonstrated in all 3 patients prior to the initiation of treatment. Streptomycin therapy resulted in excellent clinical improvement with disappearance of Donovan bodies from the lesion in the 3 patients. Two patients exhibited a relapse after the supply of streptomycin was exhausted. One patient treated with streptomycin for forty-one days was observed for two and one-half months after the completion of treatment with no evidence of relapse. It is believed that streptomycin is a valuable drug in the treatment of granuloma inguinale.

Cutaneous Manifestations of Monocytic Leukemia.—Hubler and Netherton report 50 cases of monocytic leukemia of the Schilling type which have been observed at the Cleveland Clinic Foundation Hospital since 1933. They describe the symptomatology, clinical features and hematology and place special emphasis on the incidence and types of mucocutaneous lesions seen in this type of leukemia. Monocytic leukemia may be chronic but is oftener an acute disease with severe constitutional symptoms, and it progresses rapidly to fatal termination. There is a much higher incidence of mucocutaneous lesions in monocytic than in lymphatic or myelogenous leukemia, approximately 50 per cent of the patients developing such lesions. Hypertrophy of the gums accompanied with areas of necrosis and ulceration of the oral mucosa, cutaneous hemorrhages and hemorrhages of the mucous membrane are common features of monocytic leukemia but cannot be considered pathognomonic of the disease. In monocytic leukemia the hemogram may show leukopenia or relatively moderate leukocytosis as compared with that observed in lymphatic and myelogenous types. The diagnosis is ultimately determined by the characteristics of the blood smear and the bone marrow obtained by sternal puncture. Histopathologic changes in specific lesions of monocytic leukemia cutis are usually characteristic, but it is not uncommon for a general pathologist to return a diagnosis of sarcoma.

Neuropsychiatric Manifestations During Malaria.—Boshes directs attention to the variable presenting syndrome of cerebral malaria. In assessing some of the psychotic reactions incident to malaria, the role of the medication must be determined. He and his colleagues were in contact with tens of thousands of soldiers taking quinacrine as suppressive treatment, 0.4 Gm. per week. Large numbers of patients over a period of almost three years were treated for malaria in the general hospital, but not a single case of quinacrine psychosis was encountered. In the Mediterranean theater, the incidence of cerebral malaria was comparatively low. The cases that were presented to the neuropsychiatrist, especially when the Italian campaign was under way, were the bizarre, the atypical. The psychiatrist was often called to see a patient with a bursting headache, severe retro-orbital pain and backache. No focal or meningeal signs could be elicited, but the advent of a typical or atypical febrile course would lead to a series of "malaria slides" being made, with the result that the diagnosis was readily established. Malaria was a common disease in the American armed forces in the Mediterranean theater of operations. Neuropsychiatric complications simulating meningitis, encephalitis, epilepsy, cerebral tumor, vascular lesions and psychiatric disorders were encountered. "Cerebral" forms of malaria were not limited to the disease caused by Plasmodium falciparum. Plasmodium vivax and mixed infections could produce these pictures.

Toxic Effects of Intrathecal Administration of Penicillin.—Walker reviews observations made on monkeys following intrathecal administration of penicillin and reports 2 cases illustrating types of neural reaction to intrathecal administration of penicillin—radiculitis and myelopathy associated with chronic leptomeningeal thickening. Such reactions usually occur only when large amounts of penicillin are injected into the subarachnoid space. When moderate or small doses of the drug are used the complication is rarely encountered.

*Preventable Deformities in Poliomyelitis. E. W. Lowman.—p. 455.

Preventable Deformities in Poliomyelitis.—Lowman maintains that muscle shortening in poliomyelitis is the result of unreleased muscle spasm and is the basis for development of contractures; deformity is the end result of the latter. Early treatment has as one major objective the prevention of the cycle consisting of spasm, shortening, contracture and deformity. In 1944 the Bureau of Medicine and Surgery of the Navy established a center for the treatment of poliomyelitis occurring among Navy and Marine personnel. The care and management of these patients became the responsibility of the Department of Physical Medicine. Over a period of two years 88 patients were received at this hospital for treatment. Patients treated early with Kenny packing and stretching uniformly presented fewer contractures and deformities on receipt at the special center. The longer the existence of a contracture or a deformity prior to the institution of physical therapy, the worse was the prognosis for correction. The more rapidly the elimination of spastic muscular states in the acute stage, the less was the likelihood of progression to contractures. The earlier the relief of spasm, the better was the prognosis for return of function. The value of physical therapy is in inverse proportion to the time lapse prior to the institution of treatment. Deformities in poliomyelitis constitute an indictment of the adequacy of the treatment administered. In the management of 88 cases of poliomyelitis among Navy and Marine service personnel the incidence of deformities has been in accordance with these observations.

*Clinical Manifestations of Adrenal Cortical Hyperfunction. L. J. Soffer. —p. 479.

Neostigmine and Tridione in Spastic Neurologic Disorders.—Denker and Kaplan found that neither neostigmine nor tridione produced any significant therapeutic effect on muscle spasticity in 50 cases of various neurologic disorders with demonstrable increase in muscle tonus. This lack of improvement is in sharp contrast to the reported benefits from neostigmine on muscle spasm associated with such conditions as poliomyelitis, extremity fractures, rheumatoid arthritis and fibrositis and does not compare favorably with the results of neostigmine or tridione therapy reported by some investigators in the management of infantile cerebral spastic palsy. It is possible that the proposed hypothesis for the central action of neostigmine in cases of muscle spasm is in error and that the drug acts at the neuromuscular junction, relieving spasm only when it is the result of increased muscle irritability on the basis of local inflammatory processes or reflex spasm from involvement of anterior horn cells. This type of action may not, therefore, be expected to relieve spasticity based on destruction of pyramidal or extrapyramidal tracts in the central nervous system. There is the additional possibility that previous favorable reports of the action of neostigmine on diseases with muscle spasm reflect more the results of concomitant physical therapy than of the drug action itself.

Clinical Manifestations of Adrenal Cortex Hyperfunction.—Soffer thinks that in order to study the clinical role of adrenal cortex hyperfunction it is essential to use the adrenogenital syndrome due to a tumor of the adrenal cortex or to hyperplasia of the adrenal cortex as the starting point. The symptoms of the adrenogenital syndrome can be divided into three groups: (1) those associated with premature sexual and physical development, (2) those associated with signs and manifestations of increased or decreased virility and (3) those other symptoms which are part of the disease but are not manifestations or disturbances in sexual physiology. The first group includes the evidences of pseudohermaphroditism and precocious physical development. In the second category are the manifestations of male virilism in the female and signs of feminization in the male. The third group includes the development of obesity, hypertension, glycosuria, osteoporosis, purplish striae, polycythemia, dusky cyanotic discoloration of the skin, acneform eruptions and a tendency to purpura and ecchymosis. The symptoms of the first two groups are referred to as the adrenogenital syndrome, while those of the third group are known as Cushing's syndrome. There seems to be no clearcut explanation as to why some patients will show predominantly the picture of an adrenogenital syndrome, while in others the major manifestations are those of the curious metabolic disturbances referred to as Cushing's syndrome and a third group will show a combination of the two. An identical picture may be produced by a tumor of the adrenal cortex, bilateral hyperplasia of the adrenal cortex, or a tumor of the anterior lobe of the hypophysis in the presence of an ostensibly normal adrenal cortex. An identical clinical picture may be presented in the absence of any overt anatomic abnormalities in the endocrine glands. The frequency with which this disease is associated with some overt pathologic condition of the adrenal cortex and the complete reversal of the clinical picture after successful surgical treatment of such adrenal change leads one to the conclusion that these glands play a vital role in the pathogenesis of this syndrome. The diagnosis of adrenal cortex hyperfunction is made on the basis of a number of factors rather than on one isolated manifestation. The factors which should be emphasized are the typical clinical history, the characteristic physical appearance, changes in the blood electrolytes, if present, and determination of the 17-neutral ketosteroids. Intravenous pyelography may help in determining an adrenal tumor. Of even greater aid is perirenal insufflation, which may show the presence of a tumor or hyperplasia of the adrenal cortex.

Improved Potency of Relaxin Extracted from Fresh Ovaries of Sows.—Albert and his co-workers say that relaxin, a water-soluble substance of the ovary which produces relaxation of the pelvic ligaments, used to be prepared either from fresh sow corpora lutea or from semidried, defatted luteal tissue obtained as by-product from a commercial procedure for the preparation of progestin. They describe an improved method for the extraction and purification of relaxin from fresh whole ovaries of the sow. Results of tests indicated that the relaxative potency depended on the state of the reproductive system, since ovaries from pregnant animals were several hundred times as potent as those from nonpregnant animals. Material from pregnant animals being difficult to obtain, the authors extract relaxin from fresh whole unselected ovaries. The ovarian extract is ten times more potent than that obtained from corpora lutea.

Malignant Degeneration and Chronic Ulcerative Colitis.—According to Cattell and Boehme, chronic ulcerative colitis predisposes to the development of cancer in the colon and rectum. The frequency of this complication is not known. The approximately 75 cases appearing in the literature do not give a true picture of the prevalence of the complication. The authors present the histories of 9 additional patients each of whom had one or more operations at their clinic. In this series the average duration from the onset of ulcerative colitis until the development of the cancer was over nine years. In the series of 54 cases of Bargen and Sauer it was 17.6 years. During such a long interval many cases are not traceable. It is also probable that some patients die of carcinoma when the ulcerative colitis is in complete remission, and the death is not associated with the previous ulcerative colitis or it is assumed that it is a reactivation of the colitis. A second factor in this apparent paucity of cases may be that operation is not performed in most cases. Carcinoma arising on ulcerative colitis is highly malignant and metastasizes early. All patients with long-standing ulcerative colitis should be studied at frequent intervals as a means of early discovery of malignant disease; this offers the only hope of improving the present bad results.

Delayed Convalescence Following Acute Hepatitis.—Marion describes the clinical and laboratory features of a representative group of patients transferred to a final type army hospital because of failure to recover completely after prolonged hospital treatment for acute hepatitis. The medical record of 82 patients provided the data for the report. All were men, with ages ranging from 18 to 44 years, the average age for the group being 26 years. In the delayed convalescence group 35 patients recovered both objectively and subjectively after prolonged and intensive treatment. An additional 36, while completely recovered subjectively, continued to show objective evidence of mild hepatic impairment. Seven patients continued to present subjective symptoms of possible hepatic origin long after all objective evidence of dysfunction had disappeared. The limitations of available objective tests must be kept in mind. The 4 cases diagnosed early hepatic cirrhosis, if correctly classified, probably represent true progression of a continuous disease to a point where one can no longer anticipate complete recovery.

Successful Nephrectomy in a 3 Day Old Infant. R. E. Brogan.—p. 274.

Immunization of Student Nurses Against Scarlet Fever.—According to Todd two objections are commonly made to the administration of materials designed to produce resistance to scarlet fever: (1) the frequency of the occurrence of generalized reactions and (2) the belief that the immunity produced is only against the toxin and does not necessarily afford protection from bacterial invasion of the streptococcus causing the disease. The author investigated the experience with scarlet fever immunization procedures in student nurses at the University of Minnesota. Of 540 student nurses 208, or 38.51 per cent, had positive Dick tests on admission to the School of Nursing. Of the whole group 96 gave a history of having had scarlet fever; 11 of these had positive reactions to the Dick test. There were 142 students who received scarlet fever toxin inoculations and who were studied and interviewed regarding generalized reactions. Of these, 90 had generalized reactions. A total of 108.5 days of school was lost because of reactions, the range being 0.5 to 6 days. The most frequent reaction symptoms were nausea, vomiting, fever, general malaise and headache. About one fifth of the students who received five scarlet fever inoculations still had positive Dick tests six to twelve months later. Because of the frequency of generalized reactions and the time lost from school due to such reactions, it is doubtful whether scarlet fever immunization procedures for student nurses are worth while.

Gastric Atrophy and Liver Therapy.—Benedict says that for a long time gastric atrophy had been considered to be an end stage of chronic gastritis and an irreversible process. Since 1935 several reports have appeared which indicate that atrophy and hypertrophy of the stomach tend to disappear following effective treatment of pernicious anemia. Two thousand gastroscopies have been reviewed. Gastric atrophy is a definite disease of the stomach. It may be in part the result of an inflammatory process or in part the result of a deficiency factor. The diagnosis of gastric atrophy during life can be made only by gastroscopy. Gastric atrophy may be localized or diffuse. As a localized process it may occur with ulcer or cancer or mixed with other types of acute superficial or chronic hypertrophic gastritis. As a diffuse process it may be idiopathic or occur in association with deficiency diseases, notably pernicious anemia. There is gastroscopic evidence that in some cases the gastric mucosa improves after prolonged, intensive liver therapy. The high incidence of stomach tumors in gastric atrophy is borne out in this series. It seems reasonable to assume that the maintenance of a normal healthy gastric mucosa is of some help in the prevention of tumors of the stomach. The question is raised whether a healthy gastric mucosa could be of protection against carcinoma elsewhere in the body.

Pernicious Anemia and Tumors of Stomach.—Rigler and Kaplan state that pernicious anemia and epithelial tumors of the stomach develop in the same person more often than would be expected on the basis of chance alone. Evidence pertaining to the nature of this relationship is still inconclusive but suggests that the two diseases are probably linked indirectly through the medium of some common factor. Among the possible factors are hereditary or constitutional tendencies, achlorhydria, gastritis and liver therapy. In contrast with the paucity of gastric tumors discovered in nonselective mass surveys, serial gastric examination of persons with pernicious anemia has yielded a very high incidence of benign and malignant epithelial tumors of the stomach. It is suggested that a search for other conditions etiologically related to or associated with gastric cancer is a necessary prerequisite to the establishment of practical selective surveys for the early detection of neoplasms of the stomach.

Cytology of Gastric Fluid in Diagnosis of Gastric Carcinoma.—Papanicolaou and his associates report studies on the diagnosis of cancer of the stomach by the cytologic technic. The study was conducted in the department of anatomy at Cornell Medical College and the department of surgery at the New York Hospital. The clinicians in the hospital submitted contents to the laboratory without accompanying clinical information. The specimens were obtained by emptying the fasting stomach with an ordinary Levine tube. An equal volume of 95 per cent alcohol was immediately added to the aspirated specimen, and this was sent to the laboratory. By this method 137 cases have been studied. Of the 27 patients having cancer, 10 gave false negatives, 7 suspected and 10 positive diagnoses. Three of the 10 cases that were missed proved to be scirrhous cancers. There seems little hope for the accuracy of this method in this type of tumor, for desquamated cells are likely to be scanty or totally absent. There were no false positive reports in the 110 patients who were free of cancer but there were 9 false suspected reports. The authors emphasize the preliminary nature of this work. There are many technical problems that remain to be studied. It is hoped that its accuracy and usefulness in clinical cases suspected of being gastric cancer will be increased.

Modified Technic for the Induction of Hypnosis. J. M. Schneck.—p. 77.

Ambulatory Electroshock.—The material on which Kerman bases his report is composed of 262 patients consecutively treated at his office on an ambulatory basis. Of this number 20 have been excluded from evaluation. Among the remaining 242 there were 152 with affective disorders and 77 with schizophrenia. The ambulatory electroshock treatment was of benefit to 191 and was ineffective in 51. Twenty-three of the 51 had discontinued electroshock treatments prematurely. Over 50 per cent of the patients, or 127, recovered. Fifteen patients required subsequent hospitalization. Electroshock therapy given at the psychiatrist's office frequently prevents hospitalization. Such avoidance of commitment is of real benefit to the patient.

Methionine Liver Injury Produced by Carbon Tetrachloride.—Drill and Loomis point out that although Miller and Whipple reported in 1942 that the toxicity of chloroform anesthesia for protein-depleted dogs was decreased by the administration of methionine, recent studies that they and others have made have not shown any protective effect of methionine against liver damage in dogs produced by carbon tetrachloride when a normal protein diet was fed. They decided to make a more exhaustive study in dogs of the therapeutic effect of methionine at different levels of protein intake. Three acute experiments with a normal protein diet (20 per cent and 41 per cent casein) and dose levels of 0.5 and 0.25 cc. of carbon tetrachloride per kilogram were performed. Supplements of methionine were without effect on the dye retention, serum phosphatase or pathologic changes in the liver. Methionine was also without effect in preventing or decreasing the degree of liver injury, both functional and histologic, in a chronic study on dogs receiving a normal protein intake (20 per cent casein) and 0.25 cc. of carbon tetrachloride per kilogram twice a week for sixty-six days. Supplements of methionine were also without effect on the liver injury produced by 0.125 cc. of carbon tetrachloride per kilogram in dogs receiving a low protein intake (8 per cent casein) for three and one-half or sixteen weeks, as judged by functional and pathologic changes in the liver. There is no evidence of a beneficial effect of methionine on liver injury produced by carbon tetrachloride when either normal or low protein intake is used.

Prefrontal Lobotomy: Indications and Contraindications.—On the basis of observations in 450 cases of prefrontal lobotomy followed for a period of several months to more than ten years Freeman and Watts have developed some ideas regarding indications and contraindications. The principal phenomenon on which the prognosis is based is the severity of the emotional response to abnormal ideas. When the effective component is strong there is a good chance of success; when it is weak, failure is likely. The attitude of the family toward the patient is a strong factor in his recovery to an adequate social existence. Age, duration of psychosis, type of psychosis and associated physical disease are of lesser importance. Cruelty, avoidance of responsibility and flight into alcohol before the development of the psychosis are contraindications. Response to shock therapy is not a reliable guide, and this form of treatment can be used to the detriment of the patient.

Bari Harbor Mustard Gas Casualties.—In December 1943, after the Allies had captured the southern portion of Italy and the port of Bari was being exploited as a major supply point for the drive north, German planes raided the harbor of Bari. Ammunition ships and tankers in the harbor were hit. These blew up, setting fire to other vessels and covering a large expanse of water with oil and gasoline. A ship loaded with approximately 100 tons of mustard gas and a large quantity of high explosive munitions was hit and exploded, the explosion disseminating the mustard gas. The 617 mustard gas casualties that occurred at this time were the only large scale group of mustard gas casualties seen in the war. There were 83 fatalities among the 617 casualties. The deaths were due primarily to exposure to a mustard in oil solution. Unusual hemodynamic changes and shock constituted the dominant initial picture. Blast injuries of sublethal severity were an important pulmonary complication, on which the superimposition of exposure to relatively mild vapor inhalation proved unduly serious and fatal. Systemic effects were severe and of greater significance than has been associated with mustard burns in the past. Many questions referable to changes in the liver, kidney and hemopoietic system remain unexplained. The type of casualty described is not likely to be reproduced to this degree in the tactical employment of mustard if the opportunity for prolonged absorption is obviated. The definitive treatment of mustard casualties proved discouraging.

Total Gastrectomy.—Smithwick explains that the earliest symptoms of carcinoma of the stomach are often mild and insidious and may consist of nothing more than indigestion, loss of appetite or easy fatigability. There is a great need for earlier diagnosis and operation if the survival rates are to be improved. Carcinoma of the stomach is responsible for more deaths per year than cancer of any other organ and for approximately 30 per cent of the total annual cancer mortality. Because of the recent decrease in operative mortality following total gastrectomy, it seems proper to utilize this operation somewhat more frequently, particularly in cases in which a lesser procedure may jeopardize the chance for cure because of an inadequate margin of safety beyond the gross limits of disease. A closed (aseptic) method for esophagojejunostomy is described. This technic of anastomosis may further reduce the operative mortality by minimizing the hazard of peritonitis due to local contamination. The procedure has in other respects been as satisfactory as open methods of suture and has been found useful in all portions of the gastrointestinal tract. Two patients whose operations are described are living and well after five years and two months and ten and a half years respectively following total gastrectomy for carcinoma. The latter appears to be the longest recorded survival following total gastrectomy for carcinoma.

Carotid Sinus Syndrome.—According to Cattell and Welch the carotid sinus syndrome occurs as the result of a hypersensitive state of the carotid sinus reflex. The first or vagal type of carotid sinus reflex is characterized by bradycardia, asystole, cardiac arrhythmia, hypotension and cerebral anoxemia which may lead to convulsions and unconsciousness. The second or depressor type is characterized mainly by vasodilatation and a fall in blood pressure. The third or cerebral type is characterized by sudden unconsciousness with no change in pulse rate or blood pressure. The second type is least common and usually accompanies one of the other two types. The diagnosis of hyperactive carotid sinus is made from the history and by inducing an attack of syncope by making digital pressure over the carotid sinus with the patient in the upright position. Patients in whom the symptoms are mild and the attacks occur infrequently may require nothing but reassurance. If possible, fatigue, worry and emotional upsets should be eliminated. The patients should not turn the head quickly. Surgical treatment is indicated in patients in whom the symptoms are severe and incapacitating, in those in whom medical treatment has been ineffective and in those who have the mixed or the cerebral type of response. The authors report 3 cases. Their operation consists in stripping the common, internal and external carotid arteries at the bifurcation, sectioning the carotid sinus "nerves" and removing the intercarotid tissue. The patient is allowed out of bed on the second postoperative day and may be discharged any time thereafter.

Treatment of Causalgia Arising from Gunshot Wounds.—Freeman says that the diagnosis of causalgia was made on the basis of the relief of pain by paravertebral injection of procaine in 114 Chinese casualties selected from 2,167 cases of gunshot wound of the extremities. The causalgia was severe in 20 of these cases. Sympathetic block by paravertebral injection of procaine produced permanent relief only in mild cases. Partial recurrence of pain was noted in 4 of 6 patients following preganglionic sympathectomy or ganglionectomy. Ganglionectomy combined with periarterial sympathectomy of the subclavian artery gave complete relief of pain in 7 cases of moderately severe and severe causalgia of the upper extremity. In the long-standing cases of causalgia, even though the pain was relieved the functional results were poor because of secondary fibrotic changes in the soft tissue of the hand. Early relief of pain is essential in order to prevent the development of soft tissue changes. This relief can best be obtained by early reparative surgery followed, when necessary, by paravertebral injection of procaine; this was proved in 4 cases. Radical sympathectomy should be reserved for patients in whom it is impossible to obtain clean healing of wounds which involve the nerves or in whom the pain persists.

Testosterone Propionate in Advanced Carcinoma of Breast.—Since their preliminary report on the use of testosterone propionate in advanced carcinoma of the female breast, Herrmann and his associates have treated 11 additional cases with osseous metastases. With 3 exceptions they were treated exclusively with testosterone propionate administered intramuscularly. The exceptions were patients in whom previous irradiation of osseous metastases had failed to control the pain. These patients improved with subsequent androgen therapy. Symptomatic improvement was manifested by 8 patients within two weeks after onset of therapy. The bone lesions remained quiescent for a variable time after the androgen therapy was terminated. When pain recurred it could be controlled by additional androgen therapy. It appears that in many cases a favorable status can be maintained until pulmonary or liver metastases develop. When this occurs the patient usually dies within a relatively short time despite the continued administration of androgen. The favorable effects on the bone metastases in the present series have been obtained with smaller amounts of testosterone propionate than were used in cases previously reported. The effective dosages were 100 and 200 mg. biweekly or 100 mg. triweekly. The androgen induced amenorrhea, but the menses returned after the treatment was stopped. One patient was asymptomatic as long as she was kept amenorrheic by testosterone propionate, but she developed pain in the metastatic area when the androgen was withdrawn and the menses returned. Facial hirsutism, deepening of the voice and acne were undesirable sequels. An increase in libido was noted in many patients. All patients gained in weight. The authors conclude that testosterone is of value in osseous metastases of breast carcinoma.

Pyribenzamine in Erythema Nodosum.—Parker and his associates obtained favorable results with "pyribenzamine" in 2 cases of erythema nodosum. In both cases lesions appeared to be erythema nodosum. In 1 the biopsy specimen was compatible with periarteritis nodosa, but there was no other clinical or laboratory evidence of periarteritis except for the skin lesions. The lesions disappeared rapidly in both cases when "pyribenzamine" was given. Such rapid improvement has not been seen with bed rest alone or with other forms of therapy.

Incidence and Cause of Icterus Neonatorum.—Fetal blood was collected from the umbilical cord before pulsation had ceased from the umbilical vein by venipuncture, and from the artery after cutting but before ligation. Children's blood was obtained by venipuncture of a scalp vein or by incision of the skin of the heel. Diagnosis of icterus neonatorum was made on the basis of hyperbilirubinemia in the cord blood or postnatal blood of an infant otherwise normal. Higgins and Stanier found that the incidence of icterus neonatorum, as judged by hyperbilirubinemia of the cord blood or postnatal blood, was 81 per cent. There is a greater chance of a severe and prolonged hyperbilirubinemia in a premature than in a mature infant. The view that the condition results from excessive hemolysis in early postnatal life is rejected on the basis of hematologic observations. Evidence derived from studies of the plasma proteins and Takata-Ara reactions is not conclusive. Fecal bilirubin studies support the view that icterus neonatorum is due to hepatic immaturity.

Congenital Hypertrophic Pyloric Stenosis. — Todd reviewed 112 cases of congenital stenosis. Diagnosis was made on the following evidence: (1) history of projectile vomiting, constipation and, usually, loss of weight; (2) visible gastric peristalsis; (3) palpable pyloric tumor. Confirmatory evidence in the form of barium roentgen examination was only undertaken in the year 1938 (8 cases); in the remaining 104 cases the presence of a palpable pyloric tumor was taken as evidence of the disease. Two series are differentiated in these medically treated cases of congenital hypertrophic pyloric stenosis. Series *A* comprises 40 consecutive cases, with 2 deaths; series *B* comprises 72 cases treated at the same hospital over an eight year period, with 10 deaths. The cases in series *A* were followed up clinically and radiologically. The subsequent physical and mental development of the patients was not affected by the pyloric stenosis, but the delay in emptying time of the stomach when seen at the follow-up examination was proportional to the severity of the condition as judged by the length of hospital treatment. The cases in series *B* were followed up clinically, and some were submitted to radiologic examination. The results tend to confirm those of series A. The author thinks that medical treatment should be the routine method unless the patient is grossly dehydrated. Surgical treatment should be undertaken if medical treatment is ineffective after a seven day trial. Surgical treatment is indicated in patients who are grossly dehydrated when first seen, or in whom the birth weight was below 6½ pounds (2,950 Gm.). Surgical treatment is contraindicated in infected patients because of the risk of fatal gastroenteritis.

Partial Gastrectomy for Simple Ulcer.—In the 132 cases reviewed by Watson all patients were subjected to partial gastrectomy by the Billroth II, Mikulicz, Kronlein, Hofmeister, Reichel or Polya modification. One hundred and twenty-nine of the patients were interviewed; 3 replied by letter. The general impression gained from these patients is that partial gastrectomy is definitely worth while. There is still a residuum of cases in which patients are not improved after this operation. Some suffer intensely from the postcibal syndrome. Others experience recurrent ulceration. The amount of stomach to be removed should not be less than 60 per cent. The problem of the length of the loop needs further investigation clinically, but there is evidence that the shorter the loop, the greater the safety from ulceration. The operation of pyloric exclusion even in its modern form is still not free from criticism from the point of view of postoperative acidity. Anemia has long been held up as a major complication after partial gastrectomy, but the results in this series have reduced this to its correct place of minor importance.

Study of 1,405 Cases of Gastric Cancer.—Harnett reviews observations on 1,405 patients with cancer of the stomach treated in London hospitals during 1938 and 1939. The operability rate was 49.2 per cent and the resectability rate 17.3 per cent. The operative mortality for all radical operations averaged 32.9 per cent, ranging from 25.4 per cent for the Polya method of partial gastrectomy to 90 per cent for total gastrectomy. The survival rate for all radical operations averaged 23.1 per cent of traced cases after excluding operative fatalities; it ranged from 21.5 per cent for the Polya method to 44.4 per cent for the Billroth I method. Age incidence, weight loss, frequency of lymph node metastases and other factors are analyzed and compared with similar figures from the Mayo Clinic. In the London series the patients were on the average older and the disease more advanced. Resection before the lymph nodes were involved gave 60 to 63 per cent of normal expectation of life over a five year period. After involvement of the lymph nodes resection gave only 40 to 43 per cent of normal life expectancy. The average for all patients, including those not treated, was 27.4 per cent of normal. Women showed the best survival rate.

Metallic Foreign Body in Systemic Venous Circulation.—The patient reported by Davey and Parker had sustained a shell wound in the left clavicular region. The fragment, which measured 1 by ¼ by ¼ inch (2.5 by 0.6 by 0.6 cm.), was lying in the lumen of the left innominate vein; it passed from there during operative intervention into the right auricle. During an attempt to remove it from the auricle, with the patient tilted in the reverse Trendelenburg position, it passed down the inferior vena cava to the right common iliac vein and was finally removed from the right internal iliac vein. As far as the authors know, such a surgical adventure with the survival of the patient is unique in medical history.

Granuloma of Uterine Tube Due to Surgical Glove Talc.—Roberts describes 7 cases of silicious granuloma, 2 occurring in appendectomy scars and 5 in the fallopian tubes. All occurred in patients who had undergone a previous laparotomy. Microscopic examination revealed the presence in the lesions of doubly refractive material. This is considered to be talc deposited at the earlier operation. Several of the tubal lesions had been previously diagnosed as tuberculous. The question is raised whether some cases diagnosed as tuberculosis of the endometrium may not also be silicious granuloma. The presence of this type of lesion in the fallopian tube can cause pelvic pain and apparently sterility.

2:43-82 (July 12) 1947

*Choice of Drugs in Treatment of Duodenal Ulcer. A. H. Douthwaite.—p. 43.

Bornholm Disease in the Tropics. W. M. Jamieson and D. M. Prinsley.—p. 47.

Note on Causation of Sudden Death. R. Richards.—p. 51.

*Hemiplegia in Young Adults. G. J. Dixon.—p. 53.

Stress Fracture of a Metatarsal in a Young Child. L. D. Rutter.—p. 55.

Drugs in Treatment of Duodenial Ulcer.—Douthwaite states that the belladonna alkaloids have a pronounced effect on the motility of the gastrointestinal tract, especially in the direction of quelling abnormal contractions. Belladonna also influences the emptying rate of the stomach, but it does not influence acidity. To be effective the dose must be large enough to cause persistent dryness of the mouth. Vagotomy for duodenal ulcer is wholly unjustifiable, because belladonna can achieve all the good results claimed for such a surgical measure without the danger and permanent mutilation that it entails. Alkalis and other antacids have such a transient and variable effect on gastric acidity that they might well be discarded. If given they should be combined with olive oil. Their danger lies in masking the symptoms while the disease progresses. Continuous milk drip feeding often completely neutralizes free hydrochloric acid in the stomach. Cannabis indica is a valuable sedative in the acute phase. While experimental evidence favors harmlessness of smoking in chronic ulcer, many sufferers find that smoking produces or increases the ulcer pain; hence, it should be limited. Mustard, vinegar, curry and strong alcoholic drinks are chemical irritants and should be avoided.

Hemiplegia in Young Adults.—The 35 cases selected for study by Dixon were instances of unilateral pyramidal palsy seen in service personnel between the ages of 20 and 40. Nineteen of these patients had only minor degrees of hemiparesis, and in these a convincing cause was found. Seven of them were observed among 30 consecutive cases of cerebral tumor, 6 among 30 consecutive cases of disseminated sclerosis; others had hysteria or hemiparesis due to syringomyelia. In all these 19 patients the onset of paralysis was insidious. The remaining 16 patients with severer palsies all had a sudden stroke; thus it would seem that strokes resulting in permanent hemiplegia are not infrequent in young adult life. Although many of these patients showed evidence of cardiac disease likely to give rise to emboli, the majority had no such condition. It is suggested that this phenomenon might be due to either a venous thrombosis in the Rolandic system of veins or a hemorrhage, thrombosis or embolus in the cerebroarterial system. Sepsis in the jugular vascular bed, recent pulmonary disease and a tendency to abnormal elevation of the blood pressure are frequent associated observations.

Technic of Laryngeal Anesthesia. R. R. Macintosh.—p. 54.

Electro-Encephalographic Changes in Migraine.—Dow and Whitty point out that there is reason to expect electroencephalograms to exhibit a persistent generalized dysrhythmia more often in migrainous than in normal subjects, for migraine and epilepsy are genetically associated. The authors limited their inquiry to 51 cases of recurrent headache beginning before the age of 25, showing no irreversible neurologic change over a period of three years and having also at least three of the following five features: (1) a family history of similar benign headache; (2) a preheadache phase (aura) of transient visual-field change, dysphasia, paresthesias or weakness of monoplegic or hemiplegic distribution, or "psychic" changes of a stereotyped pattern; (3) hemicranial distribution at some stage in its course; (4) amelioration by vasoconstrictor drugs or by mechanical occlusion of the common carotid or its branches, and (5) association with nausea or vomiting. Electroencephalographic abnormalities were found in 30; generalized dysrhythmia in 14; symmetric bilateral episodic activity in 12, and a persistent focal abnormality in 4. Exaggeration of a previous abnormality was noted only at the period of aura or early headache in 5 of 8 cases and after the administration of ergotamine tartrate in 3 of 5 cases. The authors consider it worth while to make electroencephalographic studies in all cases of migraine, for accumulation of such records will aid in the understanding of constitutional dysrhythmias. If correctly timed, they may also help to correlate clinical observations with cerebral localization.

Clinical Significance of Achlorhydria.—Brummer says that, although British and American authors no longer ascribe much clinical significance to achlorhydria, the establishment of the presence of achlorhydria is of undisputable value in the differential diagnosis between addisonian pernicious anemia and other macrocytic anemias. In Finland the physician may often have to differentiate addisonian pernicious anemia from macrocytic anemia due to fish tapeworm. If the presence of free hydrochloric acid can be established, addisonian pernicious anemia can be ruled out. On the other hand, the presence of achlorhydria makes a gastritis probable. Regarding the importance of hydrochloric acid for the digestive process, the author says that to some extent it promotes the digestion of protein but apparently is not indispensible to it. Achlorhydria is not accompanied with disturbances in the motility of the stomach and the intestine and also apparently not in the intestinal bacterial flora. Dyspeptic distress and a tendency to diarrhea are not more common in achlorhydric patients than in other persons. Therapeutic results supposedly obtained with hydrochloric acid do not prove that hydrochloric acid would be necessary for digestion, because the usual therapeutic doses of hydrochloric acid have no effect on the reaction of the stomach contents. Thus achlorhydria is of no great importance from the standpoint of digestion or as a cause of digestive disturbances.

Significance of Renal Lesions in Hypertension.—Halonen and Salomaa point out that the connection between renal lesions and hypertension is receiving more attention than usual in recent years. However, with the exception of glomerulonephritis and of nephrosclerosis, the causal relation of other renal diseases to hypertension is still obscure. In studies on 122 hypertensive patients at the Wihuri Research Institute they found that whereas previous infectious diseases apparently are of no importance in the etiology of hypertension, renal lesions are. They noticed the frequency of pregnancy toxemia and of operations in the pelvic cavity in the past history of hypertensive women. Various urologic changes, often quite slight, were observed in 43, or more than a third, of the patients with hypertension. The authors also collected 120 instances of unilateral renal lesion from postmortem material, and the blood pressure data of these cases were compared with those of 240 control cases of corresponding age. The incidence of hypertension was almost equally high in these two groups, and in 59 cases with bilateral renal lesions it was only slightly higher than in the controls.

Allergic Rhinitis and Bronchial Asthma in Bakers.—Linko studied 328 workers at bread factories, bakeries and pastry shops who came in contact with flour and found that 66, or about a fifth, had a clinical allergy to flour. Forty had nasal symptoms, 20 had both nasal and asthmatic symptoms and 6 had only symptoms of asthma. Considerable blood eosinophilia was observed in 19 of them, but there were no pathologic lymphocyte counts. Exposition tests were made in 50 cases, and 43 gave positive results. "Family predisposition" did not have a decisive influence in the genesis of allergy to flour. Symptoms developed on an average within eleven years from beginning work in a bakery, but in 32 cases signs had appeared before ten years had elapsed, which is earlier than is considered the average in other countries.

*Cytologic Changes of Liver in Cardiac Insufficiency. I. Costero and R. Barroso-Moguel.—p. 337.

Cytologic Changes of Liver in Cardiac Insufficiency.—Costero and Barroso-Moguel studied livers obtained from necropsies on 500 persons with cardiac insufficiency in the Hospital General de México. They conclude that liver cells do not show any changes which could be related to the appearance and intensity of "regurgitation" jaundice. Jaundice in these patients is due to the collapse of the intratrabecular bile capillaries at the level of atrophic zones of the liver parenchyma. Stages through which atrophy of liver passes during congestive heart failure are (*a*) congestion of the central veins with intense anoxemia and moderate compression of liver cells, (*b*) hyperplasia of the reticular endothelium forming the wall of sinusoid blood capillaries, (*c*) elaboration of precollagenous (reticular, argyrophilic) fibers by this hyperplastic reticular endothelium, (*d*) intense compression of the trabeculae through spontaneous retraction of the recently formed fibers, (*e*) collapse of the intratrabecular bile capillary and compression atrophy of liver cells constricted by retractile fibers, (*f*) fragmentation of trabeculae into isolated cells and (*g*) reabsorption of the isolated atrophic cells. Jaundice appears only in those cardiac patients in whom these two fundamental conditions are fulfilled: (*a*) a sufficient number of intratrabecular bile capillaries have been collapsed, (*b*) the great part of the cells which evacuated their bile through the obstructed capillary retain their functional integrity. It seems that the atrophic liver cells retain their function even after their isolation in the fibrotic sites of the cardiac liver, if one takes into account the lack of cytologic alteration and the existence of bile pigment in their cytoplasm.

When the secreting pole of the compressed cells has ceased to exist, the bile and other products of cell activity are shed into the blood stream, causing the appearance of jaundice. The process of depolarization is extrinsic in nature, since the chain of phenomena which reverses the direction of the flow is not in the secreting cell but arises from the mechanical obstruction of its normal draining mechanism The *multiple miliary* hemorrhages commonly found in rheumatic disease as a consequence of the changes in the wall of small blood vessels are sometimes the cause of extrahepatic jaundice, as shown by the Van den Bergh test. This form of jaundice is independent of the anatomic changes present in the liver of these patients.

Archivos de Medicina Infantil, Havana

*Nontuberculous Spontaneous Pneumothorax in Infants. R. Valdés Diaz and J. Diaz Rousselot.—p. 65.

Nontuberculous Spontaneous Pneumothorax. — Valdés Diaz and Diaz Rousselot observed the condition in 30 out of *10,830 infants treated in three Cuban clinics for infants.* Bronchopneumonia was the most frequent cause. Cough, pain and dyspnea were the early symptoms. Respiratory silence during auscultation, with absence of vocal fremitus and presence of tympany are of diagnostic value. The roentgenograms clarify the diagnosis and show the type and degree of collapse. The differential diagnosis from diseases which cause dyspnea is based on the clinical and x-ray examinations The most frequent and serious complications are mediastinal hernia and cardiovascular disorders. *The younger the infant, the more serious the prognosis.* Serial roentgenograms are of value in the diagnosis. The treatment consists of rest and the administration of oxygen, penicillin and sedatives. The authors report 63.3 per cent of recoveries.

*Intestinal Necrosis: VI. Review of Literature on Disorders Resembling "Intestinal Necrosis." J. Edelhoff.—p. 228

Vaccine Treatment of Typhoid.—According to Hansen, Italian authors use a vaccine in the treatment of typhoid that is prepared by adding to a typhoid bouillon culture successively small quantities of blood from typhoid convalescents, so that in the end the blood amounts to 2 or 3 per cent of the culture material. This is then kept at 37 C. until the majority of bacilli have become lysed, which is indicated by the fact that the fluid portion of the material becomes clear. Phenol is added to the clear fluid, and the resulting substance is used as vaccine in that from 0.5 to 1 cc. is administered intravenously or 1 to 3 cc. intramuscularly or subcutaneously. Since the mortality in the 1945-1946 typhoid epidemic in Germany was somewhat higher than usual, Hansen decided to use the vaccine. The extremely unfavorable results obtained in the first 6 adults led to its abandonment. The administration of the vaccine was followed by sudden increase in temperature and by severe chills. Then the temperature decreased to subnormal values. Leukocytosis regularly resulted after the vaccine injection. The most catastrophic effect was the severe hemorrhagic reaction which developed in 4 of the 6 patients. There was prolonged hematemesis, bloody stools and pulmonary, renal and muscular hemorrhages. In 2 of the 4 patients the severe hemorrhagic reaction resulted in death, and the 2 who survived had a prolonged convalescence with severe anemia. In a fifth patient there existed indications of a hemorrhagic pulmonary infarct. Only 1 of the 6 patients was entirely free of signs of hemorrhagic reaction. The author suggests an allergic reaction, which is determined by the fact that the bacillus and its toxins have a damaging effect on the endothelium and the capillaries and that the bacillary antigen subsequently produced sensitization and shock.

Tuberculosis in a City of the Ruhr Coal Mining Region. —Küpper shows that in Gelsenkirchen, a city in which heavy industry and coal mining predominated and which had a population of 320,000 before the war and now has about 250,000, mortality and morbidity of open pulmonary tuberculosis have doubled. Tuberculosis of the lymph nodes and exudative pleurisy have *multiplied several times.*

Nephrotic Hypertonic Syndrome in Diabetes Mellitus and Diabetic Glomerulosclerosis.—Horst lists renal changes that are caused by or accompany diabetes mellitus, giving particular attention to the diabetic glomerulosclerosis described by Kimmelstiel and Wilson in 1936. In the course of six months Horst observed 3 cases in which the diagnosis of diabetic glomerulosclerosis was corroborated by necropsy. In 10 additional cases the diagnosis of glomerulosclerosis was made clinically. Five other diabetic patients, although they had exhibited no clinical signs of glomerulosclerosis, showed a mild form of this disorder at necropsy. The clinical symptoms of the disorder include albuminuria, hypertension, hypertonic retinitis and a nephrotic syndrome in the presence of diabetes mellitus. The course is malignant and advances in exacerbations. Death follows within months or several years. The terminal stage is characterized by renal and cardiac insufficiency or by encephalomalacia. The disease occurs almost exclusively in diabetic patients but is independent of the severity of diabetes, of a tendency of acidosis, of insulin medication and probably also of the duration of diabetes. Histologically the process is characterized by hyaline degeneration, capillary sclerosis, arteriosclerotic processes, degenerative conditions in the tubules and interstitial changes.

Review of Literature on Intestinal Necrosis. — In his study Edelhoff points out that the entity intestinal necrosis which is characterized by endemic occurrence, a definite symptomatology and a characteristic pathologic and microscopic picture has not been described previously in the surgical literature. Under the term "phlegmon of the intestinal wall" and related terms sporadic cases have been described which somewhat resemble this intestinal necrosis in a series of articles in recent issues of the *Deutsche medizinische Wochenschrift.* Crohn in 1932 separated from this group a definite entity which was designated as "regional ileitis" or "terminal ileitis." *The majority of the phlegmons of the intestinal wall are* inflammatory processes, which are the result of septic metastasization or of regionally advancing processes. It is noteworthy that these processes of the intestinal wall occur with greater frequency at times of deficient nutrition.

Supradiaphragmatic Bilateral Vagotomy in Gastric or Duodenal Ulcer. H. Wulff.—p. 1226.
Resection of Pancreas. E. Perman.—p. 1228.

Surgical Treatment of Hyperthyroidism.—Djørup says that preoperative iodine treatment, irrespective of the preparation used, has been the most important factor in bringing down the operative mortality from 10-15 per cent to 2-3 per cent. With the recent medical methods of examination thyrogenous heart disorders have now become an indication for operation and the results are good. Strumectomy for cardiac disturbances of nonthyrogenous origin gives poor and impermanent results. Special attention is directed to avoiding the symptomless paralysis of the recurrent nerve by more careful exposure of the upper pole of the gland and by ligation of the inferior thyroid artery. The recent surgical aids—blood transfusion, examinations of the water balance, intravenous injections and the new wound remedies—have contributed largely to the improvement in the operative results. New and effective means have been acquired for treatment of the formerly intractable lesion of the parathyroid gland.

*Pathogenesis of Pigmentary Retinitis. E. Redslob.—p. 290.

Pigmentary Retinitis.—Redslob reports pigmentary degeneration of the choroid and of the retina in a girl aged 12 years. An arterial spasm causing temporary blindness of six weeks' duration resulted from vaccination against smallpox at the age of 14 months. The choroid is considered to be the seat of proliferation of tissue associated with neoformation of vessels. This proliferation may be caused by an inflammatory process, and pigmentary retinitis may therefore be considered a form of chorioretinitis. The family history was negative for pigmentary retinitis. In cases of degeneration of the retinal pigment, two groups must be differentiated. The first group includes the independent forms, in which not heredity but injuries and infectious diseases may play an important part; the reported case of postvaccinal degeneration is an example. The second group includes cases in which heredity may be considered a pathogenic factor. Retinitis is associated with other morbid conditions dependent on the genes which influence not only the retinitis but also the neurovegetative centers of the mesencephalon, the hypophysis and other parts whose involvement may produce deafness and polydactylism. The autonomous types of pigmentary retinitis belong to the first group; those of the second group represent but one symptom of a larger syndrome. Very likely the two groups differ also in appearance and development.

*Streptomycin in Treatment of Tuberculous Meningitis. H. Wissler and M. Streit.—p. 445.
Delivery in Breech Presentation at Maternity Hospital in Geneva. A. Turrettini.—p. 447.
Characteristics of Arterial Tension in Course of Parathyroid Osteitis (Recklinghausen) and of Paget's Disease. M. Schachter.—p. 449.

Streptomycin Treatment of Tuberculous Meningitis.—Wissler and Streit report the case of a child aged 2½ years, whose mother had a severe case of open tuberculosis. When there developed in the child fever, stiffness of neck and changes in the cerebrospinal fluid, tuberculous meningitis was thought of and the diagnosis was later corroborated by animal experiments. Treatment with streptomycin was begun at once in the form of seven daily intramuscular injections. The total intramuscular daily dose was 525 mg., or 40 mg. per kilogram of body weight. Since only small quantities appeared in the cerebrospinal fluid, two intrathecal injections were also given; half of the 100 or 200 mg. dose was given in the morning into the cisterna, the other half in the evening into the lumbar region. The intrathecal treatment was continued for fifty-four days. The intramuscular injections were continued for twenty-five days. Since the cisternal punctures always resulted in several hours of somnolence and faintness, it was sometimes difficult to say what was caused by streptomycin and what by the meningitic process. The child gradually improved, but there is evidence of labyrinthine disturbances and other defects. The tuberculous meningitis or perhaps the streptomycin may cause permanent damage in the form of blindness, deafness, labyrinthine disturbances and defective intelligence. The authors regard the described patient as not yet definitely cured. The fact that the cell count in the cerebrospinal fluid is still increased makes caution necessary, and a relapse after several months is a possibility.

*Electroencephalographic Study of Sensory Dominance of One Cerebral Hemisphere. L. Cornil and H. Gastaut.—p. 421.
Employment of Bacteriophage in Treatment of Bacillary Dysentery. J. Karpisek.—p. 422.

Sensory Dominance of One Cerebral Hemisphere.—Cornil and Gastaut studied the encephalograms of 120 adults and of 30 children between the ages of 5 and 12 years with regard to the sensitive-sensory dominance of one of the cerebral hemispheres. More than 50 per cent of the normal persons presented an asymmetry in the amplitude of the alpha rhythm, and the less ample rhythm was always located opposite to the half of the body used with preference, i. e. at the side of the dominant hemisphere. Blocking of the alpha rhythm by opening the eyes or by performing mental arithmetic caused a more complete attenuation of the alpha rhythm at the same side. Occipital rhythmic potential waves induced by intermittent rhythmic lighting of the retina were often asymmetrical, and the largest amplitude was always obtained at the side which at rest showed the less pronounced amplitude; the rhythm is in general of a larger amplitude and is more regular and more rhythmic on the dominant hemisphere than on the dominated one. It is suggested that there is a richer conveyance of sensory and particularly of visual messages on the side of the dominant hemisphere in relation to the other. The dominant cerebral hemisphere (the left side in the righthanded persons) "receives" more sensory messages, while it "conveys" more motor signals than the opposite side. The reaction of blocking the alpha rhythm, which in the course of mental effort is more important on the dominant hemisphere, proves that this hemisphere plays a predominant part in the process of application of the mind and probably in other processes of psychic life.

*Treatment of Pelvic Infections of Genital Origin with Local Injections of Penicillin. A. Sicard and J. Arbid.—p. 433.
*Influence of Anatoxin Immunization on Mortality Rate of Diphtheria. A. Besson.—p. 433.
Experimental Treatment of Visual Disturbances Caused by Arsenical Trypanocides with Intravenous Procaine Hydrochloride. H. Lorofi. —p. 435.

Penicillin in Pelvic Infections of Genital Origin.—Twelve women between the ages of 27 and 38, 7 with pelvic peritonitis and 5 with pyosalpinx, were treated by Sicard and Arbid with five to ten local injections of 50,000 to 100,000 units of penicillin. Eight of the 12 were postabortal cases. The injections were made into the pouch of Douglas or into the lateral cul-de-sacs. There was a drop in temperature after the first injection. Patients who had been in bed for months recovered within two weeks. Previous treatment, consisting of Delbet vaccine, sulfonamide and general penicillin administration, was ineffective. Local penicillin therapy is recommended for cases of long continued pelvic peritonitis without suppuration and of pyosalpinx which is cooling slowly.

Anatoxin and Mortality Rate of Diphtheria.—Statistics presented by Besson for the period 1944 to 1946 show that in Paris 539 out of 3,374 patients with diphtheria were immunized with Ramon's anatoxin (diphtheria toxoid). Of the 3,374 patients 1,112 were 6 or less than 6 years old and 102 of these died; 618 were between the ages of 7 and 15 years and 13 of these died, and 1,644 were 16 years old or older and 38 of these died. Only 1 of the 539 immunized persons, a child less than 6 years old, died. The incidence of diphtheria was the lowest in the age groups between 7 and 15 years, although the school age has always been considered the classic period of diphtheria; it is also the period in which immunization is carried out on the largest scale. The conformity of these data with those reported from the health department of the city of New York and from Great Britain and Denmark is emphasized. The incidence of diphtheria was reduced considerably by systematic prophylactic immunization in many countries, and although immunization may not be considered a definite safeguard against diphtheria it is practically one against death from diphtheria provided treatment along classic lines, particularly intensive serum therapy, is instituted.

Book Notices

Surgery of the Hand. By R. M. Handfield-Jones, M.C., M.S., F.R.C.S. Second edition. Cloth. Price, $5.50. Pp. 161 with 101 illustrations. William Wood & Co., Mt. Royal & Guilford Aves., Baltimore 2, 1916.

The author states that this monograph is written primarily for general practitioners, industrial medical officers and house surgeons, and for that reason he has avoided overloading the pages with details of major surgical reconstructions and obscure diseases. He has carried out his task exceedingly well. The text is clear and concise, and except for a few minor details one would agree wholeheartedly with everything he says.

A chapter of introduction and discussion of general principles is followed by brief chapters on the distal phalanx (felon and paronychia), lymphangitis and a more extensive discussion of tendon sheath infections and infections of the palmar spaces. A brief chapter on complications and sequelae of hand infections is followed by a longer discussion of restoration of function. Section two, comprising one third of the volume, is devoted to injuries, congenital and acquired defects and tumors of the hand.

In the treatment of acute lymphangitis (p. 29) the author advises compression of the arm close to the axilla with a blood pressure cuff. "Compression is maintained for eight hours, released for one hour and then resumed for forty-eight hours. . . . A special nurse will be required to keep watch on the pressure reading of the sphygmomanometer." This method, often called Bier's passive hyperemia, seems both unphysiological and illogical. The author says that by this means time is given for the defense mechanism of the body to mobilize its resources instead of being submerged "by a 'knock-out' blow." It would seem much more logical to permit the excretory mechanism and the detoxifying mechanism of the body, which physiologists agree depends largely on the liver, to function as promptly and effectively as possible rather than to attempt to dam back bacterial toxins in tissues which are not functionally adapted to neutralize them. One wonders if the prestige of a distinguished name has not served to perpetuate in textbooks, if not in actual practice, a method of treatment which has little to recommend it.

A second principle which the author stresses is covering the infected hand and the injured hand with a bare minimum of dressings. He would abolish hot fomentations from the whole realm of surgery, and apply only small light dressings to an injured hand. ". . . retention of mass dressings can do much harm. Darkness and warm dampness encourage bacterial growth. . . ." (p. 119). It seems a little strange that a countryman of Gamgee and of the multitude of British surgeons who have emphasized the compression of injured and inflamed tissues to limit the pouring out of serum and exudate should ignore this important principle. One might well believe that if to the hand illustrated in figure 80, page 120, a compression bandage had been added, the obvious tension and swelling of fingers and metacarpus could have been avoided. That warm wet dressings are not always carefully applied and often are used for too long a time are not sound reasons for discarding an effective method of relieving pain and helping to localize infection.

The audience for whom this volume has been prepared can accept it with few reservations. It is filled with sound advice and it should help definitely to secure more effective and thoughtful care for patients with infection and injury of the hand.

Social Insurance Financing in Relation to Consumer Income and Expenditures. By S. J. Mushkin, Anne Scitovszky and Leila N. Small, Division of Finance and Economic Studies. U. S. Federal Security Agency, Social Security Board, Bureau Memorandum No. 63. Paper. Price, 45 cents. Pp. 155. Supt. of Doc., Government Printing Office, Washington 25, D. C., 1946.

This memorandum might be called a social insurance man's work sheet. It contains his assumptions, and his calculations of what would be the effects of social insurance in the United States in future years based on these assumptions. The authors have contributed a summary of economists' criticisms of social security during the thirties. They complain that in the prewar period critics of the social security program failed to distinguish between the actuarial aspects of social security funds and the total spending aspects. All this is included in part I.

Part II is devoted to a calculation of what will happen to social security funds in the hypothetical year 195x, under three different assumptions of degree of full employment, and a discussion of the problem of financing social security, as then amended, till the end of the century. These discussions deal with the relative rates of contributions and of benefit payments but also make carefully detailed calculations of effects on total spending, following the assumptions of Keynes. The author calculates that benefits will outrun contributions somewhere between 1975 and 1990, using several different assumptions.

Part III presents the problem of financing a full dress social security plan, as outlined in the 1943 and 1945 Wagner-Murray-Dingell plans. Methods followed are identical with those of section II. This section is particularly interesting for the inclusion, on pages 74 and 75, of tabular material comparing private expenditures for medical care before and after the institution of the complete social security coverage. In general, the material indicates vastly increased expenditures for groups whose incomes fall below $2,000 a year; no diminution for groups in higher incomes, although to these groups total costs will be higher because of addition of insurance charges to services they would purchase anyway. On page 81 is a table presenting the fiscal impact of this total coverage in the hypothetical year 195x.

Part IV presents alternative methods of approaching paying for social security; modification of pay roll contribution rates, tax bases and contributor shares.

An appendix on methodology completes the impression of the whole being a work sheet, the calculations based on hypothetical assumptions. Suggestions are made, for instance, concerning proper numerical values for the propensity to consume.

Diseases of the Chest with Emphasis on X-Ray Diagnosis. By Eli H. Rubin, M.D., F.A.C.P., F.C.C.P., Attending Physician, Division of Pulmonary Diseases, Montefiore Hospital and County Sanatorium, New York. The Principles of Surgical Treatment. By Morris Rubin, B.A., M.D. Cloth. Price, $12. Pp. 685, with 355 illustrations. W. B. Saunders Co., West Washington Square, Philadelphia 5, 1947.

This book contains a store of information about diseases of the chest. The illustrations, with twenty-four plates in color, were carefully chosen and are well reproduced. The book is composed of six sections. Section I contains four chapters in which fundamental material is presented on anatomy, the uses of the x-rays in examination, physiology, and symptoms and signs of pulmonary disease. The six chapters in section II deal with the pneumonias. All known forms are carefully considered and the latest diagnostic and therapeutic procedures are included. One chapter is devoted to sulfonamides and antibiotics.

The eight chapters in section III pertain to pulmonary tuberculosis. The procedures necessary to arrive at accurate diagnosis are discussed in considerable detail. All forms of treatment are brought to date, including recent advances in chemotherapy. The nine chapters in section IV are devoted to nontuberculous chronic pulmonary diseases of the lungs and bronchi. Cancer, bronchiectasis, bronchial asthma, pulmonary cystic disease and emphysema are well presented from all points of view. The great importance of bronchial obstruction is so recognized by the authors that two entire chapters are given over to this subject. Diseases of the mediastinum, diaphragm, pleura and heart-lung disease are presented in six chapters of section V. Two of these chapters deal with the mediastinum in a splendid manner.

The last four chapters of the book, constituting section VI, are devoted to the principles of surgical treatment of various chest diseases. This includes the surgery of empyema, lung abscess, bronchiectasis, cancer, tuberculosis and benign tumors. The management of chest injuries, including hemothorax, pneumothorax, crushing chest wounds and thoracoabdominal injuries are presented in the last chapter.

The book is designed for use by general practitioners, sanatorium physicians, and medical students and radiologists. From its title one might suspect overemphasis of x-rays in diagnosis. Actually, this is not true. While the x-rays are given their well deserved place, the relative values of other phases of the examination necessary for completing the diagnosis are well presented. This book can be highly recommended to all physicians in the groups for which it was written.

Hypnotism Today. By Leslie M. LeCron, B.A., and Jean Bordeaux, B.A., M.A., Ph.D. Foreword by Milton H. Erickson, M.D., Director of Psychiatric Research, Wayne County Hospital, Eloise, Michigan. Cloth. Price, $4. Pp. 278. Grune & Stratton, 443 Fourth Ave., New York 16, 1947.

Probably few leading psychiatrists today use or recommend the use of hypnosis as a psychotherapeutic technic. It is true, however, that dynamic psychiatry as now practiced owes its major development to the observations of Freud and other associated workers on hypnotized subjects. Posthypnotic suggestion made it possible for Freud to demonstrate the presence of the unconscious without any possibility of doubt. Working with hypnotic subjects, he was able to demonstrate also that it was possible to bring unconscious memories into consciousness. At the present time most psychiatrists believe that the use of sodium penthothal (or a similar drug) is just as efficacious as hypnotism and has the particular advantage of allowing for a transition period between unconsciousness and consciousness which is of great value in bridging this gap and makes it possible to combine during the same period the working through of material which was verbalized during the unconscious state. Grinker and Spiegel in Men Under Stress give a classic example of how valuable this procedure may be. The present volume fulfils its title in bringing to the reader the present status of hypnotism. LeCron and Bordeaux, who have had many years of experience, do an exceptionally good job of presenting the subject. The book has an excellent chapter relative to the history and background of hypnotism. The principles of suggestion, posthypnotic suggestion, autohypnosis and autosuggestion are clearly and concisely delineated. Part II, which is devoted to hypnotherapy, may precipitate considerable difference of opinion. However, every chapter is well worth the reader's time and thought. The book is well written. The references, bibliography and index offer a wealth of sound psychologic reading material for those who are seriously interested in the progress of modern psychiatry.

Food Inspection Notes: A Handbook for Students. By H. Hill, F.R.San.I., F.S.I.A., A.M.I.S.E., "Ollett" Gold Medallist, and E. Dodsworth, M.R.San.I., M.S.I.A., Chief Sanitary Inspector, Borough of Harrogate. Second edition. Fabrikoid. Price, 6s. Pp. 125. H. K. Lewis & Co. Ltd., 136 Gower St., London, W. C. 1, 1947.

The second edition of this little pocket size book follows four years after the first edition and constitutes a digest or summary of present day knowledge of foods and their inspection. About half of the book is devoted to meat inspection and the remainder to poultry, rabbits, game, fish, shellfish, milk, milk products, canned foods, other foods, food poisoning and food sampling. Dogmatic statements are made with reference to controversial issues. For example, acidophilus milk . . . "exerts a beneficial influence on digestive organs." The food poisoning portion of the book needs revision. The authors still accept the theory (for which proof is lacking) that Salmonella produces toxins which are heat stable and may give rise to food poisoning symptoms in man in the absence of living Salmonella organisms. This book contains much valuable information for health workers concerned with food inspection.

A Handbook on Diseases of Children Including Dietetics and the Common Fevers. By Bruce Williamson, M.D., F.R.C.P., Physician, Children's Dept., Royal Northern Hosp., London. Fifth edition. Cloth. Price, $4.50. Pp. 408, with 87 illustrations. Williams & Wilkins Company, Mount Royal and Guilford Aves., Baltimore 2, 1947.

While this little volume succeeds in covering a wide range of pediatric subjects, a single paragraph is allotted to the discussion of many important disorders. It is not sufficiently extensive to be used as a textbook in pediatrics. To the general practitioner who wishes to refresh his memory on the bare essentials of diagnosis and treatment of diseases of children this book will be found helpful.

The Development of Inhalation Anaesthesia with Special Reference to the Years 1846-1900. By Barbara M. Duncan, D.Phil. Cloth. Price, $12. Pp. 640, with 161 illustrations. Publications of the Wellcome Historical Medical Museum New Series, II. Published for the Museum by Oxford University Press, 114 Fifth Ave., New York 11; Amen House, Warwick Sq., London, E. C. 4, 1947.

This book aims to trace the beginnings and to follow the development of concepts and practices which have gone to the making of the science and art of inhalation anesthesia as it is today. The author has attempted to show how current beliefs and happenings which at first sight appear unconnected or only remotely connected with anesthesia affected its evolution during the period under review—chiefly the period between the winter of 1846 and the end of the year 1900. The book is illustrated adequately and is written from a considerably different point of view than most histories of anesthesia. It should be of great interest to persons concerned with medical history, especially that relating to anesthesia.

Psychological Disorders in Flying Personnel of the Royal Air Force Investigated During the War 1939-1945. By Air Vice-Marshal Sir Charles P. Symonds, K.B.E., C.B., M.D., and others. Air Ministry Air Publication 3139. Paper. Price, 7s. 6d. Pp. 344, with illustrations. His Majesty's Stationery Office, York House, Kingsway, London, W. C. 2, 1947.

This volume is a collection of papers published by the physicians who are particularly interested in psychologic problems in the Royal Air Force. Some of the papers are therefore dated as early as January 1942 and a few of them extend to 1944 and 1945. Practically every aspect of psychiatric work among air forces personnel is discussed, and the whole problem of neuroses in that service can be surveyed by reading this book. There may be minor points of disagreement, but the descriptions and conclusions are basically sound and may prove valuable to know for future wars.

Health and Rehabilitation Through Chest Training. By Samuel Delano, A.B., M.D. Cloth. Price, $2.50. Pp. 142, with illustrations. William-Frederick Press, 315 W. 35th St., New York 1, 1947.

Writing at age 86, Dr. Delano describes and illustrates his system of chest training developed over the last twenty-five years. He advocates a series of related exercises as a means of bringing about and maintaining a flexible chest, which, he contends, "is the master key to health." Advantages claimed for a flexible chest "perfectly under control" are an increased chest volume, an improved balance between the pulmonic and systemic circulations and increased respiratory and circulatory reserve. The first part of the book outlines the physiologic principles underlying the movements, while the second portion is devoted to a detailed description of the eighteen exercises. The "stunts" are carefully explained and illustrated with photographs of the author. In the remainder of the text the doctor's experience with pathologic cases is summarized. Dr. Delano is obviously an enthusiast and one who has made chest exercises his hobby. The claims he has made for the values in his prescribed movements both in health and in disease are considerably beyond those generally ascribed to such exercises. The presentation is, however, clear, concise and readable and is well worthy of study by those interested in the possibilities of such methods.

Principles of the Contact Lens. By H. Treissman, M.B., B.S., F.R.C.S. and E. A. Plaice. Cloth. Price 10s. 6d. Pp. 88, with 40 illustrations. Henry Kimpton, 25 Bloomsbury Way, London, W. C. 1, 1946.

Most of the material in this monograph on the theory, optics and fitting of contact glasses deals with the stock lenses, and since in the United States the molded, plastic lenses have almost entirely supplanted those made of glass, the book will probably find a small market. The most informative chapter for the average physician is that on indications for the use of contact lenses. The chapters on fitting and tolerance are of interest chiefly to an ophthalmologist. There are two pages about plastic lenses. The author concludes with brief remarks on alteration of refractive power, safety to the eye and instructions to the patient.

Leitfaden für Zuckerkranke. Von Dr. med. Georg R. Constam. Cloth. Price, 12.50 Swiss francs. Pp. 127, with 15 illustrations. Benno Schwabe & Co., Klosterberg 27, Basel, 1947.

This is a well arranged and clearly written manual for the diabetic patient. Relatively little space is given to theory as such. However, in the sections devoted to foods, food selection and diet, the use of insulin and the complications of diabetes, sufficient incidental background and explanation are included to inform the patient not only what is to be done but why it is done. The author's point of view as to diabetic theory and therapy is apparently very similar to that of the conservative school in this country.

Queries and Minor Notes

The answers here published have been prepared by competent authorities. They do not, however, represent the opinions of any official bodies unless specifically stated in the reply. Anonymous communications and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted on request

CIRRHOSIS OF THE LIVER

To the Editor:—**Please give me the geographic distribution of cirrhosis of the liver in the United States. Is the incidence of eclampsia common among patients with cirrhosis of the liver?**

M.D., Ohio.

Answer.—The mortality tables compiled by the United States Bureau of the Census furnish the most accurate information available on the geographic distribution of cirrhosis in this country. They show as has been recognized for many years that the disease is more commonly encountered in urban areas. Areas with large Italian or Oriental populations often show higher rates. The overall mortality rate for the disease was 8.6 per hundred thousand of population in 1940; the urban rate was 11.5 and the rural rate was 5.9. The urban rate for Ohio was 10.9; for rural Ohio, 7.1.

The 1942 mortality rates by groups of states are given in the following list:

New England states	11.7
Middle Atlantic states	12.5
East North Central states	10.1
West North Central states	7.2
South Atlantic states	5.9
East South Central states	4.5
West South Central states	5.1
Mountain states	7.0
Pacific states	17.8

States with a high mortality rate from the disease per hundred thousand of population include California (17.8), New York (13.3), Massachusetts (13.2) and District of Columbia (12.9). Much lower rates are encountered in the Carolinas (3.5), Alabama (3.7), North Dakota (4.1), Utah (4.2), Mississippi (4.1) and Texas (4.6).

More detailed information can be obtained from vital statistics reports which are published by the Department of Commerce.

As these vital statistics indicate, cirrhosis of the liver is a rare disease among women of child-bearing age. Statistics on the frequency of occurrence of eclampsia in cirrhosis have not been found. However, to judge from the gravity of infectious hepatitis in pregnant women, it would seem likely that a preexisting lesion of the liver would pursue an unfavorable course in the event of a coexisting pregnancy and that symptoms of hepatic insufficiency probably would ensue.

Conversely, it may be said that acute yellow atrophy of the liver may occur in eclampsia, and Eppinger has cited cases in which repeated toxemias with successive pregnancies have terminated in cirrhosis.

ADHESIONS IN PELVIS FOLLOWING IRRADIATION OF CERVIX FOR CANCER

To the Editor:—**Recently a patient who had had one radium treatment for cancer of the cervix died and an autopsy was performed. I was impressed by the large number of adhesions found in the pelvis. Some of these obstructed the ureters and caused a pyelonephritis to develop, which was the immediate cause of death. There was evidence of metastases to the walls of the ureter. Are massive adhesions a usual sequel from radium treatment for cancer of the cervix or a rare occurrence? In about what percentage of the cases does this sequel occur?**

William M. Bush, M.D., New York

Answer.—Adhesions in the pelvis are a rare complication of irradiation of cancer of the cervix. When adhesions are present they are usually due to previous inflammatory disease or to infection complicating the carcinoma and causing a pelvic peritonitis during the time of the treatment. Unusually heavy irradiation may cause injury to the viscera and in this way produce adhesions and permanent bowel injury.

In the case cited it would seem that the adhesions were a result of extension of the disease and that the ureteral obstruction was caused by direct invasion of the ureter by the carcinoma.

Definite statistics as to the occurrence of adhesions following irradiation are not available, but a recent study of 500 carcinomas of the cervix showed an incidence of less than 2 per cent.

RECURRENT ATTACKS OF PANCREATITIS

To the Editor:—**What is known about the treatment of recurring attacks of acute pancreatitis? A patient aged 25 had a cholecystostomy one year ago and since then has had repeated attacks of left upper quadrant abdominal pain. Blood amylase is 250 units during attacks. Cholecystogram shows a nonfunctioning gallbladder.**

Robert Srigley, M.D., Ardmore, Okla.

Answer.—Since disease of the biliary tract, especially that associated with cholelithiasis, is considered a highly significant factor in the production of acute pancreatitis, it would seem proper in a case like this to perform an exploratory operation on the gallbladder and biliary passages and to drain the common duct either by choledochoduodenostomy or by a T tube for such time as the surgical findings may dictate. If the gallbladder is diseased or if stones are present in the common duct, the prospects of achieving a cure are fairly good.

In a series of cases recently reported by Comfort and others, the greatest relief from recurrent painful seizures was obtained when patients had had prolonged (at least six to twelve months) external drainage or permanent internal drainage of the common bile duct. Choledochoduodenostomy, when feasible, gave the best results. Apparently, from 40 to 60 per cent of patients who have pancreatitis may be expected to obtain relief by surgical means.

One group of patients affected with chronic pancreatitis continue to have attacks in spite of any treatment now known. The disease may progress to complete destruction of the pancreas by necrosis and fibrosis; cysts may form and pancreatic lithiasis or calcinosis develop. The progression in such cases depends on factors as yet undiscovered. In the case of severe relapsing pancreatitis in which the pancreas has been damaged irreparably and painful seizures cannot be controlled by conservative means, total pancreatectomy may be considered. Experience with this procedure in nonmalignant pancreatic disease is inadequate to warrant final opinion as to the probable end results.

PAIN AND DISCOMFORT IN PENIS

To the Editor:—**What is to be done with a man aged 52 whose chief complaint is pain and discomfort in the penis so that he can no longer have satisfactory sexual intercourse? He has not responded to anterior pituitary injections or testosterone, and sitz baths have not proved effective. He has been examined by a competent urologist, who does not find evidence of Peyronie's disease but who does believe that there is a fibrosis (slight) of the corpora which gives less vascular space and causes pain. Complete physical examination did not reveal prostatic, blood, or degenerative disease. The general psychic reaction seems fairly good.**

M.D., Missouri.

[This question has been referred to a psychiatrist and a urologist, whose respective replies follow.—Editor.]

Answer.—When careful and reasonably rapid physical evaluation does not reveal a cause for a prolongedly painful disorder, psychologic evaluation by a psychiatrist is a requisite. This is even more patent when pain is located about the genitals, but it holds good regardless of localization or whether the pain is of the constant or intermittent variety.

For too long ignorance about nervous pathways and their physiochemistry has been allowed to get in the way of treatment. In other words patients have been taxed with the physician's inability to reason out the chemistry or the anatomy of their symptom, and treatment of proved efficacy has been withheld. While chemical and anatomic factors merit the closest attention of the investigator, they are not the central core in the field of therapy.

The inevitable result of such confusion has been the search for specific and localized relationships of disease and therefore specific forms of treatment. Accordingly there is neither place nor time for investigation of the social setting under which the disorder developed or of traumatic experiences coincident with the symptom, nor can physicians seem to become properly concerned about what sort of person this was before he became ill. The mounting tide of psychoneurotic disturbances, if by nothing else, forces attention to the patient as well as to his symptom. Patients should not be penalized because of preconceptions or ignorance—ignorance that may not be personal but rather general.

Answer.—From what can be gathered from the description given, this man must have some type of fibrosis of the sheaths of the corpora cavernosa. And whether it is called Peyronie's disease or not makes no difference with the lesion or the symptoms which they present. Unfortunately the condition is chronic and persistent, a condition which rarely if ever responds completely to any type of therapy. But the pain and sometimes some of the fibrosis may be eliminated by local application of radium, and such treatment should be considered.

UNEQUAL RESPONSE TO INSULIN

To the Editor:—A patient aged 47, who has had diabetes for many years in spite of strict diet that I have tried to vary, and various doses of insulin, both regular and protamine zinc, cannot become regulated. The patient at one time will have a reaction following a given dose of insulin and yet, on the same dosage at another time, will have as much as 4 per cent sugar. Is it possible that some people will utilize their insulin more readily at one time and not utilize it at another?

M.D., Nebraska.

Answer.—Except in the presence of an infection, acidosis or other complication, patients utilize insulin with remarkable constancy. Variations in the activity of the anterior pituitary gland, the thyroid and the adrenals as well as menstruation have an influence on the effect of insulin. As far as this patient is concerned, one must remember that one is dealing with three variables—diet, exercise and insulin—and this being true it is remarkable that insulin acts as consistently as it does. Keeping diet and exercise the same, the third variable can be adjusted to the two others by giving enough protamine zinc insulin so that the rising urine or a second specimen, voided half an hour later before breakfast, is sugar free and then, that point having been established, an adjustment can be made for unmodified insulin to care for the utilization of carbohydrate during the working part of the day. This becomes difficult if the dose of unmodified insulin required is so great as to expose the patient to a reaction. Therefore, to protect patients who exercise much and have great responsibility, as truck drivers, one can lower the dose of unmodified insulin before breakfast to a safe level but get the patient later under complete control by a supplementary dose of unmodified insulin before the evening meal.

For example, the prescribed dosage might be 8 units of unmodified and 24 units of protamine zinc insulin before breakfast (by separate injection) and 8, 6 or 4 units of unmodified insulin before the evening meal. Naturally the ratios between unmodified and protamine zinc insulin and the total insulin given vary from patient to patient and also must be consonant with the diet and activity of the individual.

The diet should be divided into three meals and three between-meal lunches. One may occassionally resort to the extreme of prescribing 3 or 4 Gm. of carbohydrate every hour on the hour, with or without a little protein, at 9, 10, 11, 3, 4 and 5 o'clock, doubling or tripling the quantity on extraordinarily active days. Few people metabolize more than 10 Gm. of carbohydrate an hour. Small crackers contain 3 to 6 Gm. of carbohydrate. One ounce of peanuts represents approximately carbohydrate 6 Gm., protein 7 Gm. and fat 11 Gm.

TOXIC EFFECTS OF TRICHLORETHYLENE

To the Editor:—Please discuss trichlorethylene as to its physical nature, toxic effects, antidotes and measures to be taken in the prevention of harmful effects from it. This chemical substance is used in one step of electroplating, I am told, and goes under the trade names of Triad and Blacko-solvent.

Neal R. Moore, M.D., Bay City, Mich.

Answer.—Trichlorethylene belongs to that series of chlorinated hydrocarbons in which chloroform and carbon tetrachloride are better known members. Trichlorethylene in industry is widely used in metal degreasing and in dry cleaning. The American Standards Association has fixed the upper tolerable limit of the substance when inhaled for long periods at 200 parts per million of vapors. Oral intake may lead to intoxication, and there are some reasons to believe that absorption by the skin is considerable. If arbitrarily the toxicity of carbon tetrachloride is rated as 1, trichlorethylene may be rated at 0.5. Two schools of thought have appraised its toxicity. One group would limit its toxic action to minor consequences such as nausea, vomiting and diarrhea, with full recognition that anesthesia is readily induced. As an anesthetic, trichlorethylene is more active than chloroform. Another group attaches greater significance to the toxic properties of the substance and cites damage to the renal and hepatic systems along with other manifestations. As a general anesthetic this substance has been favored in the presence of pulmonary tuberculosis in the belief that the respiratory tract irritation is minimal. There are no precise antidotes warding off the action of trichlorethylene. The drinking of alcoholic beverages is believed to accentuate its action, while drinking milk possibly retards such action. The best prevention is the maintenance of work exposures below the 200 parts per million maximum safe level. In commercial preparations a large number of oxidation inhibitors has been introduced, some of which may be toxic. In addition to the two trade names mentioned a score or more of others may be encountered.

CARBON MONOXIDE POISONING AND CONGENITAL DEFECTS

To the Editor:—A woman three months pregnant sustained moderate carbon monoxide poisoning from which she recovered after three days' hospitalization. She subsequently gave birth to a full term infant with a congenital dislocated hip and cleft palate. Could the carbon monoxide poisoning have any bearing as a causative agent for these congenital anomalies?

Grant P. Raitt, M.D., Webster Groves, Mo.

Answer.—The halves of the palate unite first with each other and then with the nasal septum. Beginning in the ninth week, this fusion progresses rapidly from in front backward. Fusion of the palate is completed at twelve weeks. Diarthrodial joints are characterized both by a prominent joint cavity, between the movable skeletal parts, and by a ligamentous capsule at the periphery. The joint cavity arises in the third month from clefts in the dense mesenchyme, located between the prospective bones; the capsule is derived from the denser external tissue continuous with the periosteum (Arey, L. B.: Developmental Anatomy, ed. 5, Philadelphia, W. B. Saunders Company, 1946).

Medical literature reports a 6 months old fetus delivered normally at eight months but apparently dead for two months. The mother had suffered from carbon monoxide poisoning in the sixth month of pregnancy. The asphyxia was interpreted as having modified the process of maceration (Phillips, Percy: Carbon Monoxide Poisoning During Pregnancy, *Brit. M. J.* 1: 14 [Jan. 5] 1924).

Further investigation indicates that carbon monoxide poisoning is a remote possibility but an unlikely factor in causing congenital malformations in the newborn.

GENITAL UNDERDEVELOPMENT IN BOY

To the Editor:—A patient who has been suffering from hypothyroidism for a number of years but who is now improving has a son 12 years old who also had thyroid trouble. He is large for his age and weighs about 115 or 120 pounds (53 Kg.). *He tells his mother that all the boys laugh at him when he goes in bathing with them. His penis is small*, being scarcely an inch long. A small testis can be felt on the left side but nothing on the right side, except that there might be a small testis high on the right side on pressure downward from above. Over the various clinics of the world I have seen many of these cases, but I never learned what treatment to prescribe.

J. C. Ellis, M.D., McAllen, Texas.

Answer.—Treatment for a patient like this may be outlined as follows:

1. Chorionic gonadotropin in a dose of 500 international units three times a week by intramuscular injection. It is probable that both testes will be found in the scrotum after a few weeks of this treatment, but if one testis fails to descend it may have to be brought down by operation. Treatment with this material should be continued until epiphysial closure takes place.

2. The minimum amount of thyroid necessary to maintain basal metabolism at the normal level.

3. A suitable weight reducing diet.

On this treatment the boy should improve a great deal.

ALCOHOLISM

To the Editor:—I note with great interest the query and minor note on "Moderate Use of Alcohol" in The Journal, July 12, p. 985. I have worked with the practical problem of acute and chronic alcoholism for twenty years and have studied the past and contemporary literature regarding moderate or social drinking. Those of us in practical work on the subject of alcoholism definitely feel that there are no pathologic changes due to moderate drinking. Medically, it is felt that a chronic *alcoholic addict* is one who is handled by alcohol to such an extent that it interferes with one or more of his *important life activities*, the home, community or in business. On the other hand, the social drinker is apparently able to handle alcohol so that it does not take him out of one or more of these important life activities. Social drinkers, plus their ancestry, plus early emotional hurts, plus situations, plus social pressure, may sometimes develop into chronic alcoholic addicts. There is a gamble, no matter how small on some cases. To be sure, alcoholism could not exist without alcohol; but it seems absurd to blame that substance for what the human organism does with it. The task is to teach *humanity how to use it intelligently* and to avoid its abuse. Alcoholic addicts are made, not by alcohol, but by people who use it. Alcoholism today is an outgrowth of what our culture does to some personalities. We tried to ban alcohol by prohibiting its use and made the problem worse. What we need to recognize is that alcoholic addicts are sick people. Then we shall have taken the first great step toward the eradication of alcoholism. For some simple insight for patients I would suggest that the physician refer them to my article in the June 1946 issue of *Hygeia*.

THE FUTURE OF OTOLARYNGOLOGY

Chairman's Address

JOHN MACKENZIE BROWN, M.D.
Los Angeles

It is difficult to create a prophetic analysis on any subject, particularly in the field of medical science. The most accurate predictions have usually been made on the basis of a careful study of history. The past tells one what to expect of the future. Because the history of otolaryngology has been highlighted by so many important discoveries and contributions to the welfare of the human race, it is impossible for me to approach the future of this specialty with other than optimism.

Otolaryngology in the future will become a specialty not only of surgical but also of medical practice, which should attract the ablest men in the profession. There are numerous reasons for this view. The otolaryngologist of the future will find that he is the master of a great field of scientific thought and inquiry as well as of practical medicine and surgery. The very nature of the anatomic region assigned to him is enough excuse for the preceding statement. The changes in the specialty are indeed profound and will become more so as time goes on. Those who are living in this age are fortunate to be able to see this transition—a change which is bound to be only for the best. The otolaryngologist must release himself from the bonds of conservative restraint as far as the manner of scientific thinking is concerned. He must realize that the changes in this specialty are truly blessings.

In the field of otology several years ago the physician was primarily concerned with the surgical search for infection. Otitis media, mastoiditis and its numerous complications were the compelling interests. The otologist knew that the temporal bone housed a most intricate and complicated organ, which served the function of hearing and equilibrium, but in only rare instances did he turn an analytic view toward this field. He was quite pessimistic about the subject of hearing and hearing deficiencies; he was convinced that little could be done for his patients and in view of the other pressures from septic processes was willing to forget temporarily the functional aspect of otology. Consequently, when chemotherapy and biotherapy came on the scene and drastically reduced the necessity for surgical intervention in disease of the temporal bone, many otologists found themselves at a loss temporarily, and some viewed with alarm the changing nature of the specialty. It was considered by many that there were no new horizons to be sought and that the otology of the past was a thing of glorious memory. On the contrary, it was this same blessing of chemotherapy and biotherapy which removed much of the work entailed by the search for infection and which in turn made it possible for the specialist of today and tomorrow to take an entirely new slant on the problem of disease of the temporal bone. Now that the surgical complications of the acute form of otitis media and mastoiditis have become relatively uncommon the otologist may expect to see chronic suppuration less frequently in the future; he can look forward to a period when he can turn his thoughts to the functional aspects of the ear.

That this new approach is well under way may be ascertained by the present day status of fenestration surgery. The renewed interest in vestibular diseases, including Ménière's disease, the vast and pressing clinical problem of the causation of tinnitus and the innumerable problems suddenly posed by the aviation age have resulted in an entirely new and vital interest in the functional aspects of the ear. Deafness due to otosclerosis may now be viewed with far less pessimism than was necessary in the past. Regardless of the controversial nature of fenestration surgery, it is safe to say that the procedure of fenestration of the labyrinth is a surgical approach which is here to stay. No doubt this approach will undergo modifications in the future, but the fact remains that deaf people are hearing today as the result of fenestrations of their labyrinths. It is also a fact that patients who suffered the dizziness, tinnitus and deafness of Ménière's disease have in numerous instances been greatly improved and even cured by the surgical approach to the labyrinth employed by Day and Cawthorne. One cannot overestimate the valuable work in aural rehabilitation which has been contributed by the otologic services of the various military branches of the government following World War II. The utilization of radium in the nasopharynx, with excellent results in conduction deafness and tubal obstruction, was hastened by military usage. The newer approach to the use of hearing aids and the reeducation by acoustic training of deafened adults as well as children certainly come as a distinct credit to the members of the profession. The educational treatment of the deafened child, utilizing modern pedagogic, psychologic and acoustic technics and beginning as early as possible, even at the age of 2 years, will call for the increased cooperation and support of the otologist. He finds himself daily subjected to innumerable questions from the aviation industry. Men are being catapulted into altitudes and subjected to changes in atmospheric pressure for which the human organism was not designed. The otologist must answer these questions and must know how to prevent as well

Read before the Section on Laryngology, Otology and Rhinology at the Ninety-Sixth Annual Session of the American Medical Association, Atlantic City, N. J., June 12, 1947.

as treat the new types of ear diseases produced by the air age. The acoustic trauma of war is at least equalled if not surpassed by the acoustic trauma of industry today. The aero otitis media of the conventional airplane will become an infinitely greater problem in jet-propelled aircraft. The vestibular changes incident to rapid air and subsurface travel certainly will tax the ingenuity and the knowledge of the otologist. One can only be challenged by the field of otology today; as long as there are unanswered questions in any field of scientific thought, that particular field is bound to grow. One can see the analogy in physics. The unanswered questions of the atom proved to be the motivation which finally resulted in the unlocking of atomic power.

It is true that the approach to rhinologic disease has undergone even more radical changes than has otologic practice. Rhinologists of twenty-five years ago were bent on a search for pus and infected mucosa; then eradication was the main emphasis in rhinologic practice. Today, while obstructions and pus are still present, the nose and its adnexa are now studied in the light of physiologic and chemical changes. New interpretations of allergy and bacteriology, as well as of nasal physiology, almost completely reverse the practices of the rhinologists of twenty-five years ago. The rhinologist must now broaden his own horizons to include intensive study and interest in these contributing fields. Allergy has its constant manifestations in the nose and paranasal sinuses. Proper consideration of primary allergy as well as of the frequently associated secondary infections is essential to the rhinologist. It is true that he must become much more of an internist, but at the same time he must not think that surgical rhinology is a thing of the past. Pus and obstructions are still problems. The importance of the nose in the physiologic mechanism of respiration is now more fully understood and has become an integral part of present day rhinologic practice. The rhinologist of tomorrow will find himself in a position in which he must practice reconstructive surgery of the nasal pyramid as well as of the internal nose and sinuses in order to restore normal nasal function to his patients. His surgical field has not contracted; it has greatly expanded.

The sphere of laryngology and bronchoesophagology has become a necessary part of the daily practice of every otolaryngologist. There will always be foreign bodies in the food and air passages. Unfortunately, malignant conditions in these areas are on the increase rather than on the decrease. Improvements and advances in thoracic surgery have necessitated greater cooperation between the thoracic surgeon and the laryngologist. Accordingly this particular branch has become so highly specialized and has such a constantly expanding future that some physicians have been forced to restrict their practice to this field alone.

Not only have the changes in this specialty been generated through the efforts of the otolaryngologist, but innumerable aspects of change have come from contemporaries and colleagues in other fields of endeavor. He cannot forget the brilliant contributions of his pharmacologic colleagues in the development of the sulfonamide drugs, penicillin, streptomycin and the new antihistaminic drugs, "pyribenzamine" and "benadryl." Also homage must be paid to those colleagues in physics, physiology and psychology who have contributed so much to the knowledge of the acoustic end organ. The outstanding work in acoustic physics and acoustic physiology has provided a new insight into the function of the cochlea, of the middle ear and of the vestibular apparatus. One can look forward undoubtedly also to utilization of new radioactive weapons in his practice. Radium and deep roentgen therapy are well known to all. Undoubtedly the technic of applying other radioactive materials will be developed in the near future. The use of nitrogen mustards, the administration of various isotopes and the ultimate use of the cyclotron against disease may become a part of medical practice. We are at the threshold of a new and in many ways different era in otolaryngologic theory and practice. However, at this point it is important to emphasize that in spite of all the preceding statements and in spite of all the knowledge of constant change, it must not be forgotten that certain diseases will probably always exist and, even more important, that certain fundamental considerations in surgical practice as well as in diagnosis will remain the same. Sound otolaryngologic practice will always be based on anatomic, physiologic and pathologic facts. The otolaryngologist of tomorrow, just as he is today, will have to be an outstanding clinical anatomist and pathologist. The present state of efficiency in this specialty is due to the wonderful work and foresight of the American Board, with the active support and cooperation of medical schools and hospitals. The Board cannot receive too much praise for the time and energy spent on this important educational project. I wish to add my personal thanks for the many hours spent by every member of the Board on behalf of this specialty.

In order to educate the otolaryngologist of the future to be one of the most skilled practitioners in medicine it is necessary to plan for a long period of sound basic training as well as of practical experience. Undoubtedly such a man will not only be required to possess good knowledge of medicine and surgery but will have to be adept in the meticulous technics of otologic surgery and bronchoesophagologic procedures. He will have to possess a sound knowledge of acoustic physics in order to treat properly his otologic patients. He will have to be an excellent allergist and immunologist in order to do proper justice to his rhinologic patients. He will have to master certain fundamental technics in plastic reconstructive surgery in order adequately to treat deformities of the nose. And last but far from least he must be a fine practitioner of psychosomatic medicine, so that he may properly evaluate the problems of his patients.

Now that the course of study in otolaryngology has been extended to three years, including one year of basic sciences, the problem arises as to the best method of training residents. There are two chief methods to consider. First, the student may take a nine months' academic course either at the University of Pennsylvania or Washington University or in some similar institution. This should be followed by twenty-four months in an accepted hospital or hospitals. I say hospitals because I can see how a student could take his residency to great advantage both to himself and to the hospitals by spending one year in a children's hospital and one year in a general hospital. Some hospitals are being classified by the American Medical Association as offering limited residencies. These hospitals with limited residency facilities must be adequately staffed and have sufficient beds and outpatients for proper training. The hospitals should have an adequate library and well equipped clinical laboratories. I am sure that in this country there are many such hospitals, which could be organized and set up for worthwhile residencies in otolaryngology on a limited basis. Such a move would do a great deal not only for the hospital, attending staff members and residents but especially for the welfare of the patients; and it would increase the number of otolaryngologists in training now badly needed. The other method of training is by a residency in a hospital that is equipped to give its own basic science courses or is in close proximity to a medical school where the proper facilities and teachers are available. It has been found of great advantage to continue such subjects as anatomy and pathology throughout the training period of the resident. It is too well known that cold anatomy, unaccompanied by clinical practice, is soon forgotten. On the contrary, the anatomy that must be learned preceding each operation and that must be reviewed following each problem is the anatomy that sticks in one's mind. It is my plea, therefore, that a concerted effort be made at the present time to afford each resident in otolaryngology an opportunity for the study of basic science throughout his entire course of training in the hospital. I believe the student is best prepared by constant and continuous application of the basic sciences to the clinical aspect of the specialty. Whatever method is pursued in training, the Board will always see that the student is properly qualified before certification. There is every reason to look forward to a great future in the prevention and treatment of disease in the field of otolaryngology.

1136 West Sixth Street.

NEUROSURGERY (AND THE NEUROSURGEON) IN WORLD WAR II

R. GLEN SPURLING, M.D.
Louisville, Ky.

Most physicians who were actively engaged in the medicomilitary activities of World War II are one in their desire to dismiss the whole episode from their minds and fix their attention on new horizons. The physicians who were not active participants in those activities must be weary with hearing about them, for the progress of military medicine has been widely publicized. I therefore approach my subject, neurosurgery (and the neurosurgeon) in World War II, with some degree of trepidation. On the other hand, I think it will be profitable for all neurosurgeons, whether or not they participated actively in the medicomilitary phases of the war, to consider soberly and carefully the progress of this specialty during the four years of hostilities and in the period of so-called peace which came to pass when fighting ceased, as well as to reflect on the role of the civilian neurosurgeon in the Army in time of war.

Contrary to prewar predictions, injuries to the nervous system constituted nearly 10 per cent of all battle casualties. In numbers, in seriousness of the injuries and in the duration of treatment the neurosurgical load was second only to the orthopedic load. It is impossible now—and perhaps will never be possible—to determine accurately the number of major neurosurgical casualties which occurred in World War II. There were nearly 61,000 admissions to the neurosurgical centers in the Zone of the Interior, and it is likely that the over-all figure for these injuries was close to 100,000.

The management of a neurosurgical load of this size was a colossal task. It was difficult because of its magnitude and because competent neurosurgeons are not numerous. It was made more difficult—and unnecessarily difficult—by certain circumstances on which I shall comment later. But from every standpoint the task was well done.

The success of the neurosurgical therapeutic methods employed in World War II has already been recorded in the literature, and the details need no repetition. My purpose in this paper is twofold: (1) to summarize the procedures and policies in the major categories of neurosurgical endeavor, that is, head injuries, spinal cord injuries and peripheral nerve injuries, particularly as they differed from previous civilian procedures, and (2) to analyze briefly the role of the civilian neurosurgeon in the United States Army during World War II and in the future.

THERAPEUTIC POLICIES AND PROCEDURES

Head Injuries.—The management of acute penetrating wounds of the brain in World War II followed, with no important modifications, the basic concepts formulated by the late Harvey Cushing for the management of those injuries during World War I. Unlike the neurosurgeons of that war, however, the neurosurgeons of World War II had almost perfect control of the infections which seemed inevitable in the earlier war. Thanks chiefly to chemotherapy, to liberal quantities of whole blood and blood plasma and to rapid evacuation by air, it was possible to make adaptations of those principles to military and tactical circumstances which even Cushing, with his imaginative outlook on neurosurgical problems, could not have dreamed possible in 1917 and 1918.

The neurosurgeon of World War II soon learned that unless the patient's condition was deteriorating it was not necessary to hurry him into an emergency operation for a penetrating wound of the brain. The front line surgeon, therefore, was able to concern himself with urgent cases, in which delay could not be tolerated, for he could with a clear conscience send the patients whose need was less urgent to hospitals in the rear for definitive surgical treatment. This policy reduced morbidity and saved lives. Moreover, it was of great usefulness from the tactical point of view, since it kept beds in the forward zone cleared for urgent casualties.

An important technical advance in the surgical treatment of penetrating wounds of the brain was the introduction of tantalum plate. Most casualties who survive this type of wound are left with unsightly scars and deformities from cranial defects, for which reconstructive surgical intervention is necessary. Cranioplasty with tantalum seems completely to have solved this problem. Preliminary work had been done with tantalum in civilian neurosurgery prior to the war, but Army neurosurgeons perfected the technic of the method and expanded its usefulness far beyond anything that had been achieved in civilian practice.

A second important development in respect to penetrating wounds of the brain is still in progress. Epilepsy is a not infrequent sequel of this type of wound, and there is much left to be learned about it. After the war had ended, the Surgeon General accepted the sug-

---

Read before the Section on Nervous and Mental Diseases at the Ninety-Sixth Annual Meeting of the American Medical Association, Atlantic City, N. J., June 12, 1947.

gestion of Army neurosurgeons that epileptic patients be concentrated in a specialized center, where they could be intensively studied. Under the direction of Dr. A. Earl Walker such a center was established at the Cushing General Hospital and was in operation until the fall of 1946, when it was taken over by the Veterans' Administration. During the period of its operation intensive studies were made on some 300 patients with post-traumatic epilepsy. At the present time, under the direction of Dr. Walker, four other post-traumatic epileptic centers are being established in general hospitals operated by the Veterans' Administration, and the work begun at the Cushing General Hospital Epileptic Center will be carried forward in them. The importance of this work, not only for military casualties but for further scientific observations under controlled conditions, needs no emphasis.

Spinal Cord Injuries.—One of the most important and certainly the most dramatic development in military neurosurgery in World War II was the program for the care and rehabilitation of patients with injuries of the spinal cord, though by no means all the credit for it belongs to the neurosurgeons. In the acute phases of their injuries these casualties were primarily neurosurgical problems, and neurosurgeons saw to it that every man with a penetrating wound of the spine associated with paralysis had the benefit of prompt surgical exploration by experienced personnel. Neurosurgeons, furthermore, worked unceasingly to expedite the transportation of these patients from forward hospitals to rear echelon installations properly equipped for their treatment. One can fairly say that the reason that so many of these tragically wounded men are alive and rehabilitated today is because of the unending efforts of all concerned in their care to supply prompt and expert treatment to them in the first phases of their injuries.

As soon as possible after operation paraplegic patients were evacuated to the Zone of the Interior, to specialized centers in general hospitals. Here a rehabilitation program was begun, based on well recognized policies effective in civilian clinics but applied with an efficiency and a zeal and a sympathetic understanding which surpassed any comparable previous effort. Much credit for its success belongs to the urologists, orthopedic surgeons, rehabilitation and dietary experts, physical therapeutists and other specialists who participated in it. The program was and is an example of medical and surgical cooperation and efficiency unique in both Army and civilian practice. The Veterans' Administration has taken it over, and some 1,200 paraplegic patients are now continuing their rehabilitation in five adequately equipped and staffed paraplegic centers.

The ultimate goal of the Army paraplegic program was that every patient should be able to resume his former place as an independent person in civilian life. Reach, quite naturally, exceeded grasp, but the rewards were nonetheless fruitful. Furthermore, the demonstration by the Army and the Veterans' Administration of what can be accomplished for paraplegic patients is gradually awakening the public to the civilian need for a similar program. In the United States today a thousand or more healthy young adults each year are suddenly rendered helpless by injuries to the spinal cord. At the present time it is next to impossible to find hospital space for them after the emergency phases of treatment have been completed. Modern rehabilitation facilities for civilians are practically nonexistent. The Army-Veterans' program is a challenge to civilian communities to provide adequate care for these unfortunate men and women, and to set as their goal the high standards established by the Army and Veterans' Administration in the paraplegic program.

Peripheral Nerve Injuries.—In one respect the most significant contribution made by Army neurosurgeons during World War II had to do with peripheral nerve injuries, for this is a problem which can be solved only in time of war. In peacetime the busiest civilian clinics do not see enough material of this sort to permit authoritative conclusions as to methods of management. In World War I the opportunity was there for the taking, but it was lost in spite of the numbers of peripheral nerve injuries which occurred, because no accurate and comprehensive follow-up studies were made.

One of the earliest efforts of neurosurgeons in World War II was to see to it that the opportunity was not lost a second time. It has not been. Early in 1944 a Peripheral Nerve Registry was established through the efforts of Dr. Barnes Woodhall, and by October 1945, when registrations were discontinued, some 8,000 peripheral nerve sutures had been registered. The registry has been taken over by the Veterans' Administration, and regular assessments of the progress of regeneration will be made by competent and impartial observers in five specially equipped centers. The follow-up study is planned to cover a five year period. When once these statistics are completed and have been analyzed and interpreted, the results of peripheral nerve surgery in World War II will be unequivocally clear, and the pattern will be established for the proper management of similar civilian injuries.

Certain conclusions are possible even at this time. It has been established beyond all reasonable doubt that the optimum time to suture a divided peripheral nerve is within three to six weeks after wounding. It has been clearly established that by careful coordination of personnel and facilities the majority of peripheral nerve injuries can be given definitive treatment within that optimum time, even in an active theater of operations, regardless of whether or not a bone injury is present also. It has been clearly established that the time-honored custom of splinting an extremity because of damage to a major nerve trunk is, in the absence of an associated fracture, not only useless but actually harmful. It has been clearly demonstrated that by early application of competent physical therapy the fixed, ankylosed joint which had previously been the surgeon's bugbear in the management of all paralyzed extremities will almost never develop.

In another field of peripheral nerve surgery it has been established beyond all reasonable doubt that grafting of large nerve defects in the human subjects by either autogenous or homogenous grafts was as unsuccessful in practice as it was fallacious in concept. All methods and technics were tested, and the results were uniformly bad. The question may be asked why a record of failures is emphasized. The reply is that had not the ineffectiveness of nerve grafting been settled conclusively and settled early in the war, many patients would have been treated by this inefficient method and would have lost the chance of nerve regeneration which is possible by better technical methods. As it was, neurosurgeons learned, without delay, how to overcome large gaps in nerves by other means than grafting, including, as a last resort, shortening the bone of a paralyzed extremity.

THE CIVILIAN NEUROSURGEON IN THE ARMY

Shortly after the United States entered World War II, it became my duty, as Consultant in Neurosurgery to the Surgeon General, to mobilize from civilian sources for military purposes all available neurosurgical talent. I knew then, though I did not comprehend the implications of the fact, that as of February 1942 there were in the United States only one hundred and fifty-four certified neurosurgeons. The significance of the number became apparent when I found that to meet the Tables of Organization of Army hospitals would have stripped every civilian clinic of its neurosurgical personnel and still would have left the Army short.

Army needs had to be met, and the most practical solution was to train young general surgeons in the principles of neurosurgery and to train them as quickly as possible. A program of instruction was at once set up consisting of two parts. The first part, didactic lectures and anatomic dissections, lasting a month, was originally at the Columbia University College of Physicians and Surgeons and was later transferred to the University of Pennsylvania School of Medicine. The second part consisted of clinical training in the neurosurgical centers in the United States. The students, at the conclusion of their didactic and laboratory work, were sent in small numbers to each of these centers and there, by lectures, instruction in the operating theater and ward work, they were taught the practical aspects of traumatic neurosurgery. When this training period, which lasted for three months, was completed, they were assigned to evacuation and general hospitals and to auxiliary surgical groups. Approximately two hundred young general surgeons were thus trained, and the exceptionally fine service which they rendered is the background of the unprecedentedly good care which neurosurgical casualties were given in World War II. Without them it could not possibly have been accomplished.

This demonstration of the possibilities of rapid training of specialists is, to my mind, one of the major medical accomplishments of World War II. If this method is applicable to the training of neurosurgeons in wartime, it should be equally applicable to the training of other surgical specialists in an emergency. The possibility is significant from the military point of view, and it has its lessons for civilian neurosurgery. In the prewar years there was a decided tendency in all surgical specialties, including neurosurgery, to underestimate and even belittle the value of a sound background in general surgery. As the result of the war experience it can be definitely said that a background of this sort is highly important in the training of civilian neurosurgeons and that in time of war it is essential.

In spite of the excellent neurosurgical results achieved in World War II, I should be less than honest if I permitted you to believe that I am fully satisfied with them. I am not. I doubt that any military neurosurgeon—certainly any neurosurgeon who was responsible for the development of clinical policies—is fully satisfied with them. It is a comfort to believe that we did as well as we could under the circumstances. But we should have done better. I base that statement on a number of considerations, about which I propose to speak frankly.

First of all, the question arises as to why approximately three hundred neurosurgeons were needed for 11,000,000 troops when several times as many civilians had been getting along very well with less than half as many. The obvious answer is that during wartime casualty rates far exceed the rates usual in peacetime. Analysis of the casualty figures confirms the observation but makes clear that it is not the whole answer. The most reasonable explanation is that under the Army system which existed in World War II efficient use was not made of neurosurgical personnel or, indeed, of the personnel in any other of the critical specialties. Such personnel was in short supply throughout the war. Yet it need not have been. Neurosurgical shortages developed because the Medical Department operated under the Army Service Forces, which is a service of supply, and because, as a result, medical personnel was handled, from an administrative point of view, exactly as rations, guns, clothing, food and other supplies were handled. Let me assure you that that is not the way to distribute medical personnel.

A second reason for shortages in neurosurgical personnel is that the channels of command were too complicated and too cumbersome to permit of efficient operation. I am fully aware that it is necessary in wartime to decentralize authority, especially in theaters of operations, but that awareness does not prevent me from also being aware that medical personnel in short supply cannot be efficiently utilized by nonmedical commands which, with all the will in the world, cannot comprehend or visualize medical needs and medical problems.

I had the responsibility, in the Zone of Interior and later in the European Theater of Operations, of seeing to it that neurosurgical casualties received competent neurosurgical care. The Army system made it an unnecessarily difficult task. My experience—and it was not unique—was to the effect that every time a new command was established, it became one more echelon of resistance to the proper allocation and distribution of medical talent. It was to the effect that every new commander who entered the picture, whether he was a base section surgeon or commanding officer of a hospital or of a hospital center, held on tightly to all the personnel in his command whether it was needed there or whether it was not. As a consequence, many critical specialists terribly needed elsewhere were frozen in commands and were unemployed for weeks or months at a time when they could have been doing vital work in the care of neurosurgical casualties.

To substitute constructive for apparently destructive comment, let me suggest a simple solution for this problem, based on recognition of the fact that critical specialists will always be in short supply and that their services must be utilized on that concept. I would not list a neurosurgeon, or any other critical specialist, on the Tables of Organization of any field, evacuation, general or station hospital, for two good reasons. The first is that all such units are necessarily deactivated, even when fighting is heavy, for longer or shorter periods, and that during these times specialists cannot function and are therefore lost to the Army. The second is that when once a medical officer appears on the Tables of Organization of a given unit it is a major operation to detach him from it.

My suggestion is to make neurosurgeons, and all other critical specialists, members of teams which are completely mobile and so entirely self contained that all of them can be moved at a few hours' notice from one location to another as the need for their services arises. They can be moved by small plane or by command car. Standard operating supplies are always available at all Army installations, and the only impedimenta which the team would need to carry with it would be its own specialized equipment.

It is true that neurosurgeons were attached to auxiliary surgical teams in World War II, but auxiliary teams were just that—auxiliary. By the plan which I propose these teams would cease to be supplemental. They would replace the specialized personnel hitherto attached to various types of installations and, if not entirely wasted in them, at least not used to the fullest possible advantage.

In the volumes on neurosurgery shortly to be published by the Surgeon General's Office as part of the medical history of World War II we have tried to present the operational and clinical material which I have discussed, and other matters of like importance to the medicomilitary future of the country, as fully and fairly as possible. We who provided the neurosurgical care for the casualties of that war owe it to those who will come after us to record, as faithfully and honestly as we can, our errors as well as our achievements, the difficulties under which we labored and whence they arose, the problems which we encountered and the solutions which we found for them during the war or which, in the light of experience and reflection, we would now suggest for them. If the neurosurgical history of World War II is written from this point of view, and if it is made compulsory reading for the neurosurgeons of any future war, then our successors will enter on their tasks equipped for them as we of World War II were not equipped for ours.

ABSTRACT OF DISCUSSION

Dr. Barnes Woodhall, Durham, N. C.: I find it difficult to discuss Dr. Spurling's statement or to amplify it because of the fact that it lies outside of my own personal knowledge. However, on many occasions Dr. Spurling and I have discussed the possible place of neurosurgery and neurology in the event of another conflict. Although many answers cannot be given at this time, it seems to me that at least two things can be discussed, and perhaps some action taken. The first has to do with this annoying problem of specialized personnel, and I think the problem can best be illustrated by reference to the case of a colleague of mine. You will recall that many of the neurosurgeons left early in the university units, and Dr. Spurling had to get the remainder. This colleague was removed from the reserve corps because he was on the dean's essential list, and he was unfortunate enough to encounter Dr. Spurling at a hotel in Chicago. Some hours later, about 3 o'clock in the morning, after sufficient inducements, he found himself back in the Army. That is a hard way to secure neurosurgical personnel. I feel that one thing can be done, and that is that our boards can get in touch with the Pentagon, and perhaps maintain an up-to-date list of neurosurgeons who are available, because of their strong backs, for military duty, and others who might be available for total civilian care. The second point has to do with the relationship between neurosurgeons and neurologists in the military structure. As you know, there were no neurosurgeons when the war began; there were only septic surgeons in their place, and Dr. Spurling traded the classification in the Army organization table, and furthermore the neurologist was on the medical side and the neurosurgeon was on the surgical side. There was only one hospital in this country in which neurologists and neurosurgeons worked together, both being specialists interested in organic diseases of the brain. This coordination was achieved only at the expense of a considerable "rumpus," involving even the Surgeon General. This is the one hospital that achieved great things in the efficient care of patients and in promoting clinical investigation. As many of you know, I am referring to the Cushing Hospital. Certainly the tables of organization should be changed so that the neurosurgeon and the neurologist may work together and may be free of this baneful influence of the general surgeon and the general internist. Dr. Spurling did not mention the driving force behind these accomplishments, but I am happy to name the driving force and to add that Dr. Spurling achieved a place in military neurosurgery in World War II that can only be compared with the place that was achieved by his chief, Dr. Cushing, in World War I.

ULTRAVIOLET IRRADIATION OF HUMAN PLASMA TO CONTROL HOMOLOGOUS SERUM JAUNDICE

Numerous publications [1] have established that human blood, plasma or serum may harbor the agent of infectious hepatitis. This agent, believed to be a virus, has been the cause of hepatitis in recipients of human blood and plasma.[2] Because of the prolonged incubation period—two to six months—the relationship between administration of blood or plasma and the subsequent development of hepatitis is frequently overlooked.

It is easy to exclude blood donors with a history of jaundice or hepatitis and to discard blood specimens showing hyperbilirubinemia. Unfortunately, however, many persons may be unknowingly infected, for many cases of hepatitis occur without the development of typical symptoms and signs and thus pass undiagnosed. Furthermore, the virus may be present in the blood stream of the infected person for weeks before and after the acute episode of hepatitis. It is clear that administration of human blood or plasma carries with it a potential hazard of hepatitis, despite careful selection of donors.

In the absence of a satisfactory method or test for recognizing and excluding such infected blood, it is obviously desirable that all human blood plasma and serum be treated to destroy the virus of infectious hepatitis and protect the recipient of these materials from the hazard of hepatitis. Any proposed method must meet at least three criteria: 1. It must destroy the virus. 2. It must be free of harmful side effects. 3. It must be practical.

A new method of rapidly sterilizing suspensions of bacteria and viruses has been developed by Oppen-

heimer and Levinson.[3] This new method consists essentially of exposing rapidly flowing thin films of liquid for fractions of a second to a new and powerful source of ultraviolet emitting intense radiation of 2,537 angstrom and 1,849 angstrom wavelengths.

Oliphant[4] reported that serum infected with hepatitis virus and treated by this method was rendered free of the agent. Since the Oppenheimer-Levinson equipment is effective in destroying virus and since it is capable of irradiating large quantities of serum and plasma, it appeared that irradiation could be applied to plasma and serum if it had no deleterious effects on the plasma itself. The data herein presented represent a preliminary report of our studies to determine whether irradiated plasma is free of side effects from irradiation and whether it is satisfactory for human use.

The effects of irradiation of rabbit plasma were first tested. Rabbit plasma was pooled and divided into three portions, one of which served as nonirradiated control, one was irradiated for one second, and another for two and one-half seconds. Rabbits were given injections of 10 cc. per kilogram of body weight intravenously, as indicated in table 1. All of the rabbits tolerated the injection well. These results showed no evidence of toxicity from irradiation and seemed to justify experimental work with human plasma.

TABLE 1.—*Effects of 'rradiation on Rabbit Plasma*

	Ultraviolet Exposure									
	None				1 Second				2.5 Seconds	
	Rabbit 1	Rabbit 2	Rabbit 3	Rabbit 4	Rabbit 7	Rabbit 8	Rabbit 9	Rabbit 10	Rabbit 5	Rabbit 6
Temperature before injection	102.0	101.5	102.2	101.5	102.1	102.1	102.3	102.1	101.6	102.6
Temperature 1 hour after injection	102.8	102.8	102.4	102.5	103.2	103.0	103.1	103.0	101.7	103.0
Temperature 2 hours after injection	102.6	102.6	102.4	102.6	103.0	103.0	102.9	103.0	101.9	103.2
Temperature 3 hours after injection	102.1	102.8	102.9	102.4	102.6	102.9	102.6	102.8	102.2	102.8
Temperature rise	0.8	1.3	0.7	1.1	1.1	0.9	0.8	0.9	0.6	0.6
Average rise for group	1.0				0.9				0.6	

A small pool consisting of 2 liters of human plasma prepared from the blood of normal, healthy adults was irradiated, an exposure of one second being used. This exposure time was much longer than necessary to inactivate other viruses in past experiments. Three patients received 250 cc. each and a fourth received 500 cc. After administration, none of the 4 patients showed any reaction which would not fall well within the normal range.[5] These favorable results called for more extensive testing of irradiated plasma.

Plasma lot PT-4652, consisting of approximately 9 liters of human plasma prepared from the blood of normal, healthy adults, was processed in strict accordance with the requirements of the National Institute of Health, except for the additional step of irradiation, introduced just before bottling in final containers. The plasma was irradiated for approximately one-third second (an exposure time adequate to inactivate other virulent virus suspensions). A specimen was saved from this pool to serve as a nonirradiated control. The irradiated plasma on inspection showed no change in color and no change in general appearance. Specimens of the irradiated plasma were inoculated into mice and guinea pigs, which tolerated the injections well. Each of 3 rabbits was given an intravenous injection of 5 cc. of the irradiated plasma, and none showed any reaction or significant rise in temperature in the succeeding three hours. Electrophoretic studies of the irradiated human plasma and the nonirradiated control material were made.[6] The results showed "no consistent variation between irradiated and nonirradiated samples."

TABLE 2.—*Clinical Results with Irradiated Human Plasma (PT-4652)*

No. of Cases	Intravenous Injections, Cc.	Rate of Injection, Cc./Min.	Rise in Temperature	Comment
9	300	5 to 10	None	No evidence of reaction
1	350	6	None	This patient, asthmatic with osteomyelitis of the hip, experienced urticaria of face and chest
6	600	7½ to 10	None	No evidence of reaction
1	900	12	None	No evidence of reaction

Human beings have received injections from this lot of irradiated human plasma, with the results shown in table 2. Twenty-one patients received irradiated plasma in dosage from 250 to 900 cc. One patient experienced urticaria, a reaction encountered when untreated blood or plasma is used. No other reaction was observed.

It may, therefore, be tentatively concluded that controlled ultraviolet irradiation would appear to be a practical, yet harmless and safe, procedure which will free plasma (or serum) from the hazard of transmitting infectious hepatitis.

Aniseikonia.—There are twenty-one aniseikonia clinics in the United States. In our general population as many as two million persons may have complaints correctable by aniseikonic glasses which would otherwise remain unrelieved. This means that about 5 per cent of those wearing glasses would be benefited by aniseikonic correction. It may be years before enough refractionists obtain the instruments and acquire the experience necessary to prescribe successfully for this condition. In the meantime it is important for the refractionist to recognize which of his patients he should refer for aniseikonic study.—Miles, Paul W.: Factors in the Diagnosis of Aniseikonia and P[illegible] Maddox Rod Tests, *Am. J. Ophth.* **30**:885 [July] 19[illegible]

ANTIBIOTICS AND TUBERCULOSIS

A Microbiologic Approach

SELMAN A. WAKSMAN, D.Sc., Ph.D.
New Brunswick, N. J.

The recent interest in the production, isolation and utilization of antibiotic substances for the treatment of infectious diseases, especially the recognition of the fact that certain antibiotics, notably streptomycin, may find an important place in the treatment of tuberculosis, has suggested the advisability of reviewing the accumulated information on the effect of antagonistic micro-organisms and their metabolic products on Mycobacterium tuberculosis, the causative agent of human and animal tuberculosis.

Surprisingly enough, the interest in the possibility of suppressing the growth of the tubercle bacillus and of alleviating the disease caused by it date back to the early days of bacteriology. Numerous reports have been published which tended to emphasize the fact that a large number of micro-organisms, both saprophytic and pathogenic in nature, exert a pronounced effect on this bacillus.

The first attempt to treat clinical tuberculosis by means of nonpathogenic bacteria was made within three years after Robert Koch first isolated the organism responsible for this disease and within one year after this organism, which came to be generally known as Koch's bacillus, was described. The credit for the first application of bacteriotherapy to tuberculosis must go to Cantani.[1] On the basis of previous observations that the virulence of tuberculosis in corpses disappeared under the influence of putrefactive processes, Cantani in 1885 conceived the idea of treating pulmonary tuberculosis by having the patient inhale cultures of nonpathogenic bacteria. A common saprophytic organism known as Bacterium termo was used for this purpose. A woman aged 42, who had a large cavity in the superior lobe of the left lung, who suffered from fever and coughing and whose sputum test was positive, was treated by inhalation of a liquefied gelatin culture of the saprophyte, diluted with meat broth. The pathogenic organisms in the sputum were rapidly reduced in numbers and eventually disappeared completely; the fever diminished, and the patient's condition improved.

It may be of interest to quote from the original paper by Cantani, in which he expressed his ideas on the subject of bacteriotherapy and reported the results obtained in the treatment of this particular patient:

> The well known fact that certain bacteria may destroy the culture of others and also particularly of pathogenic schizomycetes, provided that they may get inside of them, suggested to me the idea of using this experience for therapeutic experiments in various infectious diseases. The first experiment was aimed at tuberculosis. I first selected Bacterium termo to combat the tuberculosis bacillus of Koch. . . . Herewith I made my first experiments on human tuberculosis. On May 4 inhalations of a pure culture of B. termo in liquefied nutrient gelatin which had been diluted with meat broth were started by means of a spray apparatus with a double rubber balloon. The expectoration decreased rapidly, and finally it ceased completely during the last days of the experiment. The number of tubercle bacilli decreased likewise, while B. termo could be demonstrated in the sputum; on June 1 the tubercle bacilli had disappeared completely from the sputum and could no longer be demonstrated while B. termo were observed in increasing numbers. There was a drop in temperature so that during the last days (of the experiment) the evening temperature no longer reached 100.4 F. (38 C.); the body weight was increased again to 39.6 Kg. The patient looked considerably better, the general condition was satisfactory; the subjective feeling of strength was improved considerably. Animals which were inoculated with the sputum (which was free of tubercle bacilli on microscopic examination) did not manifest any symptoms of tuberculous disease.
>
> (Die bekannte Tatsache, dass gewisse Bakterien die Culturen anderer und namentlich auch pathogener Schizomyceten zerstören, wenn sie auf irgend eine Art in dieselben gelangen, brachte mich auf die Idee, diese Erfahrung für die Therapie verschiedener Infectionskrankheiten experimentell zu verwerten. Mein erster diesbezüglicher Versuch war auf die Tuberculose gerichtet, und wählte ich zunächst Bacterium termo, um damit den Bacillus tuberculosis Koch zu bakämpfen. . . . Hiermit führte ich meinen ersten Versuch am kranken Menschen aus. Am 4. Mai begannen die Inhalationen einer Reinkultur von *Bacterium termo in verflüssigter mit Fleischbrühe verdünnter* Nährgelatine mittels eines Zerstäubungsapparats mit doppelter Kautschukblase. Die Expectoration nahm rasch ab, bis zum gänzlichen Aufhören in den letzten Tagen des Experiments; die Tuberkelbacillen nahmen gleichfalls baldigst ab, während B. termo darin nachweisbar wurde; am 1. Juni fehlten die Tuberkelbacillen vollständig im Auswurf, und kamen nicht mehr darin vor, während B. termo in immer grösserer Quantität darin vorhanden war. Das Fieber nahm ab, so dass in den letzten Tagen der Beobachtung die Abendtemperatur nicht mehr 38 C. erreichte, und das Körpergewicht nahm wieder bis auf 39.6 Kg. zu; das Aussehen der Kranken war sehr gebessert, der Allgemeinzustand lobenswert, das subjective Kraftgefühl bedeutend gehoben. Tiere, denen die nun mikroskopisch an Tuberkelbacillen freien Sputa inoculirt wurden gaben kein Zeichen tuberculoser Erkrankung.)

Cantani did not claim that the saprophytic B. termo would destroy the deeply infiltrated tubercle bacilli. He merely extended hope that this first experiment might lead to the isolation of other bacteria which would be used in combating various pathogenic organisms. In commenting on Cantani's experiments Babes[2] suggested in the same year that it would have been advisable before determining the therapeutic effect of one microbe on another in vivo to test such effects by pure plate cultures on gelatinized mediums.

Soon afterward, in 1888, Babes[3] demonstrated that products of various saprophytic organisms, such as the pyocyaneus, tetragenus, staphylococcus and diplobacillus, have the capacity of inhibiting the growth of tubercle bacilli; streptococci, however, appeared to be favorable to the development of the tuberculosis organism. The importance of associative organisms in influencing the course of tuberculosis was thus emphasized.

Somewhat later, in 1893, Nannotti[4] observed that tubercular inflammation of the knee joint tended to subside as a result of the spontaneous occurrence of erysipelas. The use of streptococci or their metabolic products, filtered and sterilized, resulted in a modification of the tuberculous process; abscesses grew smaller and fistulas tended to heal. These studies led Prudden[5] soon afterward to the conclusion that there

was no evidence of a specific antagonism of a certain organism toward the tubercle bacillus; the results obtained by Nannotti may have been due to simple inflammation caused by the accompanying organisms.

Prudden also observed that the presence of streptococci in pulmonary tuberculous infections modified considerably the course of the disease. Highly suggestive results were obtained in culture; namely, the growth of the streptococci prevented the subsequent development of the tubercle organism. Prudden elucidated these results succinctly as follows:

> When the tubercle bacillus and the Streptococcus pyogenes are planted together on glycerinated (5 per cent) beef broth, the streptococcus grows as abundantly as in separate control cultures, while the tubercle bacillus does not grow at all. On the glycerinated broth, in which the streptococci had grown for five days, and which was rendered sterile by filtration through porcelain, the tubercle bacillus failed altogether to grow, either when the sterilized broth was used in its full strength, or when diluted in various degrees down to four times its volume with fresh glycerinated broth.

Although the culture filtrate of the tubercle organism also had an inhibiting effect on the growth of the streptococcus, this effect was of much lesser magnitude.

These early clinical and laboratory studies on the antagonistic effects of various micro-organisms and their metabolic products on the growth of Myco. tuberculosis in culture and on the course of the disease produced by this organism were later followed by more exact studies, both in vitro and in vivo. They finally culminated in the work of Rappin [6] on spore-forming bacteria and of Vaudremer [7] on fungi which tended to establish the sensitiveness of the tubercle bacillus to the products of various organisms. This work done between 1910 and 1913 ended the first period of study of the antagonistic effects of various micro-organisms on tubercle bacilli; it also established definitely that not only living microbes but their products, now known as antibiotics, have the capacity of inhibiting and even destroying the tubercle organism both in the test tube and in the living body. Hope was thus aroused that in time a practical agent would be found for the treatment of this important and widespread disease, which has long been known as the white plague of mankind.

Before proceeding to analyze the results of the more recent investigations, especially the effects of antibiotics on tuberculosis, it may be of interest to examine certain pertinent information concerning the survival of Myco. tuberculosis in the soil and in other substrates and the production of antituberculosis agents or tuberculostatic and tuberculocidal substances by micro-organisms.

SURVIVAL OF MYCOBACTERIUM TUBERCULOSIS OUTSIDE THE HOST

The fate of the organism causing tuberculosis outside the human or animal host has received much consideration. Difficulty has frequently been encountered in demonstrating the presence of the tubercle bacillus in a given natural substrate, such as soil and water, because of lack of suitable methods and the need for animal inoculation in order to establish the true pathogenic nature of the organism. The survival of Myco. tuberculosis outside the host was found to be affected by light and by increased temperature; it was greater in the dark than in diffused light and greater at a lower than at a higher temperature.

When a culture of the bovine strain of Myco. tuberculosis was mixed with cow manure and exposed in a 2 inch (5 cm.) layer in a pasture, it remained virulent for two months in sunlight and longer in the shade. The organism was still alive on the two hundred and thirteenth day and was dead on the two hundred and thirtieth day. In running water the cells survived for more than a year.[8] It was gradually recognized that the presence and activity of nonpathogenic micro-organisms greatly affect the life of the tubercle bacillus outside the host. The pathogen survived, for example, for three hundred and nine days in sputum kept in darkness even when completely desiccated. In decomposing sputum, however, it could be isolated after twenty days but not after twenty-five days. It remained alive and virulent in cow's feces exposed on pasture land for at least five months during the winter, two months during the spring and four months during the autumn; in the summer, however, no living tubercle bacilli could be demonstrated even after two months. Feces protected from earthworms yielded viable cells even after five months.

The addition of manure to soil was believed to favor the survival of the tubercle bacillus, as indicated by the fact that a higher proportion of test animals became tuberculous when the amount of manure added to the soil was increased.[9] The presence of the organism in soil and in manure was established even after one hundred and seventy-eight days but not later. On grass the organism survived for at least forty-nine days. Rhines [10] found that Myco. tuberculosis multiplied in sterile soil as well as in the presence of certain pure cultures of bacteria; however, a certain unidentified fungus was able to check the development of the pathogen, especially in manured soil. In nonsterile soil the pathogen was slowly destroyed, the plate count being reduced in one month to about one sixth of the original. Numbers of an avian strain of the tubercle bacillus were reduced in seventy-three days from 48,000 to 1,400 cells per cubic centimeter in sewage and to 4,200 in stream water.[11]

PRODUCTION OF ANTIBIOTIC SUBSTANCES BY MICRO-ORGANISMS

Every investigator of the organism causing tuberculosis observed at one time or another that when his cultures became contaminated with molds or with bacteria the culture of the pathogen no longer grew. This inhibiting effect was believed to be due to competition for nutrients or for oxygen, or to the formation by the invading saprophyte of growth-inhibiting substances which affected the pathogen.

It was gradually established that the production of antituberculosis or tuberculostatic and tuberculocidal agents is widespread among micro-organisms; that these agents, or antibiotics, are active against various acid-fast bacteria, and that they are produced abundantly by various members of all major groups of micro-organisms, namely, fungi, bacteria and actinomycetes.

Among the fungi, the Aspergillus fumigatus group received particular attention.[12] Although this organism produces four antibiotics, the active substance responsible for the antituberculosis effect appears to be fumigacin. Among the bacteria the Bacillus subtilis group was given special consideration, especially in recent years, with subtilin coming lately to the fore as a possible tuberculostatic agent. The actinomycetes have contributed several antibiotics active against tuberculosis, namely, actinomycin, streptothricin, streptomycin and nocardin. Among these, streptomycin is recognized to be the most promising therapeutic agent for the treatment of tuberculosis, because of its desirable physical and chemical properties, its low toxicity to animals and its pronounced effect on the tuberculosis organism both in vitro and in vivo.

PRODUCTION OF ANTITUBERCULOSIS AGENTS BY FUNGI

Although it was known before the end of the last century that various fungi have the capacity of inhibiting the growth of and even of destroying various bacteria, it was not until 1913 that Vaudremer [13] first reported that certain fungi, comprising members of the Aspergillus (A. niger, A. fumigatus) and Penicillium groups, have a destructive effect on Myco. tuberculosis and that these fungi produce tuberculostatic and tuberculocidal substances. He was led to these studies by the observation that the fungi destroyed tuberculin, a phenomenon which he ascribed to the proteolytic activities of the organisms. Since tuberculin was considered as a toxalbumin, one of the constituents of the protoplasm of Myco. tuberculosis, a study was made of the effect of one of these fungi, A. fumigatus, on the tubercle bacillus. When virulent cells of this organism were suspended for twenty-four days at 39 C. in a filtered extract of A. fumigatus and the culture thus treated was inoculated into experimental animals, infection did not occur. The conclusion was reached that the fungus produced a thermostable substance, which was responsible for the antituberculous effects; this substance caused the lysis or digestion of the tubercle bacilli and rendered them nonpathogenic.

Vaudremer utilized the extracts of the fungus for the treatment of some 200 patients with tuberculosis. Although certain quite unexpected results were obtained, any conclusions based on them were considered as premature; however, the preparations appeared to be nontoxic. These results hardly justified any recommendation at that time that this method of treatment of tuberculosis be further extended. This is expressed emphatically in Vaudremer's paper:

> It is still too early to draw any conclusions with regard to the treatment of tuberculosis in man. Since 1910 we have treated more than 200 patients with extracts of A. fumigatus; the treatment was practiced in several hospitals and sanatoriums in Paris. From the facts observed one may conclude that these injections are innocuous, since they never caused a febrile reaction. Occasionally one even observes an unexpected recovery. In other cases one may observe a temporary improvement; but unfortunately the instances are still numerous in which tuberculosis takes its course.
>
> (Toute conclusion est également prématurée si on envisage le traitement de la tuberculose humaine. Depuis 1910, nous avons traité plus de deux cents malades avec les extraits d' *A. fumigatus*; le traitement a été appliqué dans plusieurs hôpitaux et sanatoriums parisiens. Des faits que nous avons observés, on peut conclure à l'innocuité de ces injections qui ne provoquent jamais de réaction fébrile. Parfois même on voit survenir des guerisons inespérées. Dans d'autres cas, on observe une amélioration passagère; mais malheureusement les faits sont encore nombreux où la tuberculose poursuit son évolution.)

Nearly a quarter of a century elapsed before fungi were again considered as organisms capable of producing substances that possessed antituberculosis properties. A real flow of contributions was started in 1940; Zorzoli [14] observed that various fungi including certain aspergilli and mycotorulae produced a thermostable substance which had a pronounced antibacterial effect on the human and bovine strains of Myco. tuberculosis. These results were confirmed by experiments in guinea pigs: when the tubercle organism was exposed for varying periods of time to the culture filtrates of the aforementioned fungi it lost much of its virulence to animals. The Oxford group [15] which investigated the potentialities of penicillin could not detect any inhibitory action of this antibiotic on the growth of the tubercle organism even in a dilution of 1:1,000.[15]

Soltys [12c] tested various fungi for their action against acid-fast bacteria; here again, A. fumigatus proved to be the most active organism. Unfortunately, he labeled the active filtrate aspergillin, a term previously used to designate the black pigment of A. niger. The antibiotic substance was thermostable, bacteriostatic rather than bactericidal, and active in a dilution of 1:10 to 1:20 against the human, bovine and avian strains of Myco. tuberculosis and in 1:50 to 1:100 dilution against Mycobacterium phlei.

Asheshov and Strelitz [12a] also observed a definite effect of A. fumigatus preparations on the Bacille Calmette Guérin strain but not on the avian strain of Myco. tuberculosis. The bacteriostatic action was greater against the former than against staphylococci, although the bactericidal capacity was lower. According to Jennings,[16] helvolic acid, or fumigacin, one of the antibiotics produced by A. fumigatus, completely inhibited the growth of the tuberculosis organism isolated from sputum in concentrations of 1:10,000. In 1:100,000 dilution the inhibition was only partial.

These results seem to point definitely to the fact that A. fumigatus is the organism of choice for the production of antituberculosis agents but other fungi also have tuberculostatic and tuberculocidal properties.

Aspergillus ustus produces an antibiotic that has the capacity of inhibiting the growth of Myco. tuberculosis and Mycobacterium ranae.[17] The active substance was extracted from the medium with ether as well as with other organic solvents. On evaporation of the solvent, the residue was dissolved in phosphate buffer of p_H 11.0; on acidification, a yellow flocculent precipitate was obtained. The preparation was effective against Myco. ranae in a dilution of 1:150,000 to 1:300,000.

Aspergillic acid, a metabolic product of Aspergillus flavus, gave complete growth inhibition of a fast-growing strain of Myco. tuberculosis in a dilution of

1:80,000 in broth, but it was not active in Long's synthetic medium.[18] The lack of activity in this medium was due to the presence of the ferric ion, which inactivated the antibiotic. It was suggested that iron is essential for the growth of Myco. tuberculosis and that aspergillic acid exerts an inhibiting effect on this organism by interfering either with the utilization of iron or with the functioning of an iron-containing enzyme system.[12b] Other strains of aspergilli were also found [19] capable of forming in synthetic mediums antibiotics active against the tuberculosis organism.

Although, as has been pointed out, penicillin has no tuberculostatic activity, ether extracts of the crude culture medium of Penicillium notatum were reported by Smith and Emmart [20] to exert a pronounced in vitro effect on the tubercle organism. A slightly favorable effect was obtained in the chorioallantoic membrane of the chick embryo and on guinea pigs. The extracts of another fungus, Penicillium cyclopium, were without effect, however, thus indicating that the production of the antituberculosis factor is characteristic of P. notatum.

More recently, however, penicillin itself, when used in concentrations of 20 to 80 Oxford units per cubic centimeter, was observed [21] to exert a bacteriostatic effect on freshly isolated strains of Myco. tuberculosis, but it was without effect on an avirulent laboratory strain; the latter actually had the capacity of destroying penicillin. When used in small amounts, penicillin may actually produce a favorable effect on the growth of the tubercle organism.

The Fusarium group of fungi also contains organisms that possess tuberculostatic properties. Carr [22] observed that a culture filtrate of Fusarium solani tested in vitro against the H 37 strain of human tuberculosis was found to decrease its vitality. An alundum capsule containing 5 cc. of medium was inoculated [23] with a culture of Fusarium and introduced into a 250 cc. Erlenmeyer flask containing 100 cc. of Long's medium, the latter being inoculated with a fresh virulent strain of the tubercle organism. The culture filtrate of the Fusarium was active in a dilution of 1:20, the substance being thermostable. A pigment, designated as javanicin, was isolated [24] from Fusarium javanicum; it was active in vitro against the human strain of Myco. tuberculosis in concentrations of 1:50,000 to 1:100,000; this pigment was relatively nontoxic.

Miller and Rekate [25] reported that culture filtrates and extracts of certain fungi were inhibitive to the tuberculosis organism. Gerber and Gross [26] designated one such extract mycocidin; its effect on the human strain of tuberculosis was both bacteriostatic and bactericidal.

Certain higher, or mushroom, fungi also produced antibiotics which possess antituberculosis properties. It is sufficient to mention clitocybin and nebularine. The first is a product of Clitocybe candida and Clitocybe gigantea; [27] it is soluble in water and in various organic solvents, such as ether, alcohol, acetone and chloroform; it is not particularly toxic, and it exerts both a static and a lytic action on the tubercle organism not only in vitro but also in vivo, in guinea pigs. The second antibiotic is found in the press juice of Clitocybe nebularis; it is a thermostable substance and is active on mycobacteria and Brucella abortus.[28] A pigment designated as lactaroviolin was recently [29] isolated from Lactarius deliciosus; the chemical composition of the substance was given as $C_{15}H_{14}O$; it inhibited the growth of Myco. tuberculosis in a concentration of 0.31 millimol per liter of medium.

Attention may be also called here to a phenomenon described as forced antagonism. By the use of a synthetic medium, with living tubercle bacilli as the only source of nitrogen (2 per cent sucrose and 0.1 mg. of living bacteria in 2 cc. of medium), Schiller [30] trained or forced beer yeasts to develop mechanisms which enabled them to digest the cells of the pathogen. In two days the yeasts developed and the tubercle organisms disappeared. The centrifuged medium contained an antituberculosis factor, since it had the capacity of rapidly digesting living tubercle bacilli, preceded by their agglutination. The tuberculolytic substance was thermolabile; its action was believed to consist in dissolving the wax of the bacterial cells. These results have never been confirmed; in one experiment the yeasts and fungi were actually superseded by the tubercle organism.[31]

This brief survey of the production by fungi of antibiotics active against tuberculosis justifies the conclusion that many are potentially active agents which vary greatly in their origin, chemical nature and activity in the animal body. Although none of these substances has so far achieved practical application for therapeutic purposes, there is hope that, in view of the relatively limited search which has been made to date, some compounds may still be found which can be utilized in one way or another—alone, as a supplement or in a modified chemical state—in the control of this disease.

PRODUCTION OF ANTITUBERCULOSIS AGENTS BY BACTERIA

A brief survey of the production of antituberculosis substances by bacteria will also reveal many highly promising observations, although at some periods this subject seemed to have been completely neglected.

Since Babes first demonstrated experimentally in 1888 that certain bacteria have the capacity of influencing the growth of the tubercle bacillus, considerable evidence has accumulated. This was followed by various observations made by different investigators that the property exerted by saprophytic and pathogenic organisms on Myco. tuberculosis is not limited to certain few forms but is widely distributed among bacteria and other micro-organisms; some of these are capable of producing active antituberculosis agents.

In 1892 Rongali[32] demonstrated, for example, that a reciprocal antibiosis exists between various bacteria and Myco. tuberculosis. Nannotti and Prudden's results in this field have already been mentioned.

Ramond and Ravaut[33] established in 1899 that when various bacteria, such as B. subtilis, Staphylococcus albus, Staphylococcus aureus and Micrococcus tetragenus, are grown simultaneously with Myco. tuberculosis, the latter does not develop. When a drop of a culture of one of the preceding bacteria is added to a culture of the tubercle organism, growth of the latter is stopped. The metabolic products of the saprophytic bacteria had a similar, although weaker, effect on the growth of the parasite. In 1902 Michelazzi[34] reported that M. tetragenus has the capacity of suppressing Myco. tuberculosis not only in vitro but also in vivo. When the micrococcus was inoculated into experimental animals, the growth of the tubercle bacillus was prevented. The favorable effect of the administration of yeast on pulmonary tuberculosis was demonstrated by Huggard and Moreland in 1905.[35] The associative growth of Clostridium perfringens and Myco. tuberculosis was observed[36] to result in a lytic action of the former on the latter in vitro but not in vivo.

In 1912 Rappin[6] observed that culture filtrates of a number of spore-forming bacteria, such as B. subtilis, Bacillus mesentericus and Bacillus megatherium, have a suppressive effect on the development of the tubercle bacillus. When culture filtrates of the bacteria were injected into rabbits infected with the tubercle organism, the development of the disease was prevented and no toxic manifestations occurred. This activity was *said to be due to the formation by the spore-forming* bacteria of antibacterial agents designated as diastases. Thus the test tube experiments on the effect of bacterial products on the tubercle organism were confirmed by studies in experimental animals. Although these results were highly significant, they did not arouse sufficient interest and were not followed up immediately.

It took more than a decade before further studies on the antituberculosis properties of bacteria were reported. Most of the investigations were centered largely on the spore-forming aerobes. In 1926 Van Canneyt[37] demonstrated that B. subtilis exerts a lytic effect on Myco. tuberculosis. Olivier[38] also demonstrated that B. subtilis has the capacity of bringing about the lysis of the tubercle bacillus in eight to twelve days.

More recently, subtilin (obtained[39] from B. subtilis) was found to inhibit the growth of Myco. tuberculosis in Long's medium, in a dilution of 1:50,000; in 1:10,000, it was also bactericidal. This substance was also effective against experimental tuberculosis in [illegible] strain of B. subtilis described as Bac[illegible] produced on a synthetic medium an agent which was active against the tubercle bacillus.[40] Other spore-forming bacteria, both aerobic[41] and anaerobic forms,[42] have now been found to cause the loss of virulence, to inhibit the growth of and even to bring about the lysis of tubercle bacilli. In some cases the culture filtrates of the antagonistic bacteria were as active as the culture itself. Some attempts have actually been made to utilize these culture filtrates in the treatment of human subjects.

Among the preparations obtained from spore-forming bacteria it may also be of interest to mention eumycin[43] and bacillin.[44] The latter was obtained from an organism isolated from soil enriched with tubercle bacilli.

Various non-spore-forming bacteria, including Escherichia coli and Pseudomonas aeruginosa are capable of exerting a pronounced tuberculostatic and tuberculocidal effect. Different strains of Esch. coli show great variations in their antibacterial action.[45] Throughout the most extensive literature on the antagonistic effects of Ps. aeruginosa and its antibiotic, pyocyanase, there are suggestions of their possible action on the tuberculosis organism. However, positive evidence has been submitted only recently. A twenty day culture of Ps. aeruginosa was found[46] to inhibit the growth of Myco. tuberculosis in dilutions of 1:80; a crude chloroform extract was effective in 1:128,000 dilution. Short exposure of the pathogen to the culture of the antagonist caused morphologic changes, followed by loss of acid-fastness and final lysis. An antibiotic substance designated as pyolipic acid was isolated from Ps. aeruginosa; this substance was characterized by decided antituberculosis properties.[47]

Certain streptococci have also been found to possess the capacity of producing antituberculosis substances. An organism described[48] as Micrococcus antibioticus was active against Myco. tuberculosis in vitro. Another coccus isolated by Mattick[49] from milk proved extremely effective against both human and bovine strains of the tubercle bacillus; this coccus yielded an antibiotic agent, nisin, which was active in a dilution of 0.000006.

This brief summary tends to establish the fact that bacteria also offer potential sources of antibiotics that possess tuberculostatic and tuberculocidal properties. Much is still to be done in this direction.

PRODUCTION OF ANTITUBERCULOSIS AGENTS BY ACTINOMYCETES

Like the fungi and the bacteria, the actinomycetes comprise a number of organisms or species which produce antibiotics active against the tubercle bacillus. Some of the active agents that have so far been isolated or concentrated are actinomycin, litmocidin, nocardin, streptothricin and streptomycin. Of these, the last named is the most promising.

There are several significant points about the distribution of antimycobacterial properties among the actinomycetes: 1. A large number of species and strains of these organisms are capable of exerting an antituberculosis effect. 2. The active substances produced by these organisms vary greatly in their chemical properties and their toxicity to animals. 3. The action of these substances on mycobacteria and other micro-organisms vary greatly. Their antibiotic spectrums range from extremely narrow ones which are active only against certain mycobacteria, as in the case of the antismegmatis factor,[50] to exceedingly wide zones when the activity is broadly distributed against gram-positive and gram-negative bacteria and even against fungi, as in the case of streptothricin.[51]

Streptomycin possesses all the desirable properties as a potential chemotherapeutic agent in the treatment of tuberculosis. Two cultures of the organism producing streptomycin were isolated in September 1943; the announcement of the isolation of streptomycin itself was made in January 1944 in a paper by Schatz, Bugie and Waksman.[52] Soon afterward, Schatz and Waksman[53] reported that streptomycin is highly effective against Myco. tuberculosis and other mycobacteria. The human strain H 37 was particularly sensitive to this antibiotic. The tubercle organism, which was inhibited by only 0.2 microgram of the antibiotic, was six or more times more sensitive to streptomycin than was Esch. coli. Streptomycin possessed decided tuberculostatic and tuberculocidal properties; it was far more active than streptothricin, a closely related antibiotic. It was also active against various bacteria both in vitro and in vivo and had limited toxicity to experimental animals.[54] Not long afterward, Feldman and Hinshaw[55] established that streptomycin is effective in the treatment of experimental tuberculosis in guinea pigs. Evidence was thus obtained of the striking antibacterial activity of streptomycin in vivo. It resulted in the resolution, fibrosis or calcification of lesions in all animals and the apparent eradication of the infection in at least 30 per cent of the animals. Positive reactions to tuberculin tests have been reversed to negative reactions, free from the organism Myco. tuberculosis.

Different strains of the tubercle bacillus, freshly isolated from patients, were found by Youmans[56] to vary greatly in their sensitivity to streptomycin. The range in sensitivity was between 0.2 and 12.5 micrograms per cubic centimeter, although in the great majority of cases freshly isolated cultures were sensitive to less than 1 microgram per cubic centimeter. On contact with streptomycin, either in the test tube or in the human or animal body, Myco. tuberculosis gives rise to resistant strains which require far greater concentrations of the drug for their inhibition or destruction. When inoculated into animals, streptomycin-resistant cultures retained their resistance and no longer responded to streptomycin therapy.[57]

Actinomycetes produce other antibiotics which are active against Myco. tuberculosis. It is sufficient to mention nocardin, produced by Nocardia coeliaca.[58] This substance is found both in the culture medium and in the mycelium of the organism. It has an inhibiting effect on the slow-growing strains of Myco. tuberculosis varieties hominis and bovis in concentration of 10 to 50 per cent of the culture filtrate; unfortunately, it has only a slight in vivo effect.

The most important chemotherapeutic agent now known for tuberculosis, namely streptomycin, has been contributed by the actinomycetes. There is no doubt, however, that other agents supplementary or superior to streptomycin will be found, because of the wide occurrence of antimycobacterial substances among members of this group of micro-organisms. The possibility that different forms of streptomycin or even different sources of this antibiotic may vary quantitatively in their antituberculosis effect has also been indicated.[59]

PRODUCTION OF ANTITUBERCULOSIS AGENTS BY HIGHER PLANTS

Finally, in order to make the survey complete, attention must also be directed to the higher, green plants which produce a variety of substances designated as "phytoncides" and which possess tuberculostatic and tuberculocidal properties. Marshak,[60] for example, obtained a crystalline preparation from the lichen Ramalina reticulata. This is a nonnitrogenous, water-insoluble substance; when it was administered subcutaneously in 10 to 20 microgram portions given once a day for a period of three weeks to guinea pigs that weighed from 350 to 400 Gm. there were no toxic effects. When the animals were infected intraperitoneally with human tubercle bacilli, strain H 37 RV, the antibiotic retarded the progress of the disease.

Other preparations derived from plants have been used at various times in the treatment of tuberculosis. It is sufficient to mention the alkaloid cepharanthine, used extensively in Japan, which is said to possess a limited toxicity and to exert a decided effect on experimental as well as clinical tuberculosis.[61]

CHEMOTHERAPY OF TUBERCULOSIS FROM AN ANTIBIOTIC POINT OF VIEW

Although the results previously presented point to the production by micro-organisms of a large variety of substances that are active against the tubercle

bacillus both in vitro and in vivo and thus offer promise as chemotherapeutic agents, streptomycin is the only one that has so far found practical application in the treatment of tuberculosis. Of a number of reports that have been submitted concerning the efficacy of streptomycin therapy in tuberculosis, only a few which have a direct bearing on the subject will be mentioned here.

To Feldman and Hinshaw[62] must go the credit for pioneering in these investigations. After being the first to demonstrate the effectiveness of streptomycin in experimental tuberculosis, they established by clinical investigations the chemotherapeutic potentialities of this drug. The criteria for a successful antituberculosis agent were summarized as follows: (*a*) the agent must be tolerated by the animal without producing irreversible physiologic derangements; (*b*) the progressive development of the disease must be reversed to nonprogressive, accompanied by resolution, fibrosis, and calcification; (*c*) the virulent infection must be eradicated, and (*d*) the effect must be produced in a reasonable time.

Clinically, streptomycin has been proved[63] to have a pronounced suppressive effect in miliary, laryngeal, meningitic, cutaneous, renal and exudative pulmonary tuberculosis. At first a small number of patients were treated, since only limited amounts and rather impure preparations of streptomycin were then available. Although the course of the disease was modified favorably and its progressive development suppressed, the result was believed to be associated with the bacteriostatic effect of the drug, and the lack of a rapid curative effect was ascribed to an insufficient bactericidal action.

As a result of treatment in the first 100 cases, Hinshaw, Feldman and Pfuetze considered themselves justified in coming to rather optimistic conclusions.[64] These can best be summarized in their own words:

> Streptomycin is an antibacterial agent which possesses the unique ability to inhibit the growth of Mycobacterium tuberculosis in vivo, both experimentally and clinically. The manifestations of tuberculosis may be suppressed both in experimental animals and in man, with at least temporary retardation of the pathologic processes as judged by objective criteria. In many instances streptomycin appears to suppress tuberculosis rather than to eradicate it, being apparently bacteriostatic rather than completely bactericidal in the concentrations which can be obtained in the tissues.

Tuberculous meningitis was definitely arrested by the use of streptomycin. Treatment consisted in the daily intrathecal administration, by lumbar or cisternal puncture, of 100 to 200 mg. of streptomycin for two to six weeks. In addition patients received by intramuscular injection 2 to 3 Gm. of the drug a day for six months. None of the patients who died in the first experiments had received intrathecal therapy, which frequently produced temporary clinical improvement that lasted only for several weeks or months.

Ulcerating tuberculous lesions of the respiratory passage, including the larynx, hypopharynx, trachea and large bronchi, have been treated in several instances, with prompt improvement of the patients in most cases; no recurrences occurred. In the prolonged treatment that is usually required for patients suffering from tuberculosis, there is the danger of an increase in resistance to the antibiotic, as was established for some of the patients. Although streptomycin did not exert a rapidly curative effect on clinical tuberculosis, it appeared to modify the course favorably by a suppressive effect on previously progressive tuberculosis.

In a discussion on the effects of streptomycin on pulmonary tuberculosis Bunn[65] has recently made the following observations: (*a*) The trend of the disease was reversed, as illustrated by the lack of spreads and exacerbations. (*b*) A majority of the patients were decidedly improved. (*c*) However, in no instance could the lesion be considered as cured. When a jury of sixteen disinterested specialists was allowed to examine the data submitted for their critical evaluation, a striking degree of agreement was obtained between the impressions of the participating investigators and those reported by the jury.

The other effects of streptomycin on the clinical course of tuberculosis were a lowering of the sedimentation rate, a dramatic reduction of fever in cases of hyperpyrexia, a pronounced gain in weight and subjective improvement. The production of sputum has usually been decidedly lessened and the cough has decreased in frequency and severity. Fourteen of a group of 47 patients gave negative sputum or gastric cultures after treatment with streptomycin.

In a group of 50 patients with miliary and/or meningeal tuberculosis who were treated with streptomycin, 50 per cent of the patients remained alive, although not all in perfect health, "but alive nevertheless, when by all previous standards, death should have taken place." Miliary lesions in the lungs have been observed by roentgen examination to disappear during the course of treatment. Total deafness occurred in 2 cases, and in 1 instance, complete depression of the bone marrow values; the latter was due to streptomycin, since its discontinuation was followed by a return of marrow function despite a progression of the miliary tuberculosis to death.

The conclusion was reached[65] that streptomycin is capable of healing certain tuberculous lesions and of serving as an adjuvant to existing forms of treatment in other types of tuberculosis. It was considered sufficiently toxic that its use must be accompanied by clinical observation and laboratory studies.

In another report on the treatment of tuberculosis with streptomycin[66] McDermott observed three significant phenomena in the majority of the tuberculous patients who received streptomycin: (*a*) a rapid, sometimes abrupt, fall in temperature and accompanying symptomatic improvement, not unlike the crisis observed in pneumococcus pneumonia; (*b*) a regression, and frequently a complete disappearance, of the pulmonary lesions demonstrable roentgenologically, and (*c*) the development of strains of tubercle bacilli which were resistant to the action of streptomycin in vitro. All three of these phenomena were most prominent in the more acutely ill patients of the hematogenous group.

In still another report[67] on the treatment of 4 children from 7 months to 3 years of age who had pulmonary tuberculosis, the daily administration of 1 Gm. of streptomycin for one month resulted in a definite improvement in the general condition of all 4 patients and regression of the appearance of pulmonary lesions.

LOOKING AHEAD

The use of streptomycin in the treatment of tuberculosis presents certain challenging problems to the microbiologist, the chemist and the clinician. Most significant of these is the development by the tubercle organism of resistance to the streptomycin, and the drug's ineffectiveness against certain forms of tuberculosis.[68] In order to overcome these limitations an intensive search must be made for other agents that would be more effective alone or combined with streptomycin. The idea suggested by Smith and McClosky[69] of utilizing the possible synergistic effect of two agents, such as "promin" (sodium p,p'-diaminodiphenylsulfone-N,N'-didextrose sulfonate) and streptomycin, appears to offer certain promising possibilities. The combination of streptomycin with certain sulfones in the treatment of guinea pigs infected with experimental tuberculosis resulted in a greater therapeutic effect than the sum of the effects of the individual components.

A turning point has now been reached in the chemotherapy of tuberculosis. Although streptomycin may not be the final answer in the treatment of this scourge of mankind—and I hope that it is not—it has opened a new path, a path of antibiotic approach to chemotherapy, an approach sought since the discovery of the bacterial nature of the disease; the control of tuberculosis may finally materialize and thus advance man one step further in his battle against disease and epidemics.[70]

The complete literature on the use of streptomycin in experimental and clinical tuberculosis cannot be presented for the simple reason that many of these papers are only now in the process of publication.

CARCINOMA OF THE ESOPHAGUS AND THE CARDIAC END OF THE STOMACH

Immediate and Late Results of Treatment by Resection and Primary Esophagogastric Anastomosis

RICHARD H. SWEET, M.D.
Boston

Until 1938 when Phemister and his associates[1] performed the first successful transthoracic resection for carcinoma of the lower end of the esophagus invading the cardia, the prospect of treatment of this disease was dismal if not hopeless. In the majority of cases in which the tumor involved the midthoracic segment, the application of the Torek procedure[2] resulted in disappointment because of the failure of this operation to provide satisfactory palliation and its inefficacy as a method of controlling the disease.[3]

As a result of several years of experience with resection and primary anastomosis within the thorax, the entire situation has changed, and the immediate and late results of treatment by resection and primary esophagogastric anastomosis may be evaluated. The elimination of the distressing dysphagia provided by this operation has been most gratifying, and the fact that a recurrence of the tumor at the site of anastomosis is exceedingly unusual insures the best palliation available for patients afflicted with this terrible disease. With regard to the possibility of cure, although more time will be required to accumulate a large series of cases in which the operation was performed long enough ago to observe survival periods of three years or longer, it is already apparent that the three to five year survival rate will ultimately approximate that of carcinoma located in other internal viscera.

The first transthoracic resection for carcinoma of the cardia to be performed at the Massachusetts General Hospital was in 1939. From then until Jan. 1, 1947, 213 patients with carcinoma of the esophagus or cardiac end of the stomach have been operated on. Resections were performed in 141 cases. Ninety-one of these consisted in transthoracic partial gastrectomy and esophagectomy followed by primary intrathoracic esophagogastric anastomosis. These cases included 27 epidermoid lesions arising in the lower fourth of the esophagus and 64 adenocarcinomas arising from intraesophageal gastric mucosa or from the stomach itself and invading the cardia. Although an appreciable number of patients with carcinoma in the midthoracic segment of the esophagus had already been treated by resection and high intrathoracic esophagogastric anastomosis just below the aortic arch, the first patient at the Massachusetts General Hospital in whom the esophagus was pulled up from beneath the aortic arch for the performance of a supra-aortic anastomosis was treated in May

---

From the surgical services of the Massachusetts General Hospital.

1944. Since that time 50 patients with carcinoma of the midthoracic segment have been treated by resection and high anastomosis. Twenty-one of these had an anastomosis just below the aortic arch, and in 29 the anastomosis was performed above the arch, frequently just below the dome of the left pleural cavity. These 50 cases were all epidermoid carcinoma histologically. Chart 1 serves to illustrate the numbers and types of cases as they have occurred from year to year.

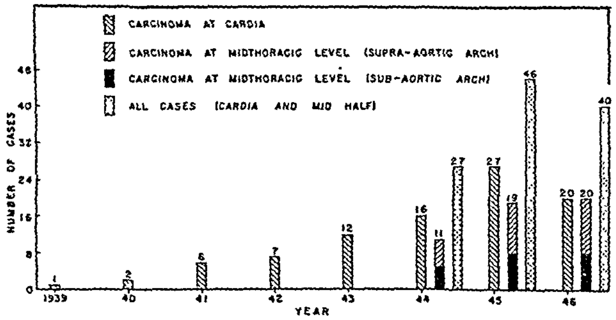

Chart 1.—Numbers and types of cases as they have occurred from year to year.

RESECTION AND PRIMARY ESOPHAGOGASTRIC ANASTOMOSIS

Technic of Operation.—No important changes have been made in the technic of resection and primary esophagogastric anastomosis used in each type of case since previous reports were made.[4] A description of the technical aspects will therefore be omitted.

Preoperative and Postoperative Care.—Little change has been made in the preparation and postoperative care of these patients since previous reports.[4a] The most important development has been the routine use of penicillin and more recently of streptomycin for the prevention of infection. The use of these antibiotics has almost eliminated the element of sepsis, which was formerly the most frequent cause of postoperative complications and the principal cause of death in the immediate postoperative period.

Other changes such as elimination of the continuous use of the inlying Levin tube, earlier ambulation, more frequent application of the operation of ligation of the superficial femoral veins to prevent pulmonary embolism and earlier administration of oral feedings are features of minor importance.

In recent months all patients have been given the benefit of consultation with a cardiologist,[5] who has taken a serious interest in the possibility of reducing the occurrence of cardiac complications. Since the problem of infection is now under better control, such complications have caused the most frequent and the most serious difficulty. The routine use of a low sodium diet to diminish the possibility of the development of acute pulmonary edema and the preoperative and postoperative administration of quinidine sulfate in an effort to prevent the occurrence of cardiac arrhythmias appear to have been highly beneficial, although a larger experience will be necessary before accurate conclusions may be drawn.

SURGICAL EXPERIENCE WITH TWO HUNDRED AND THIRTEEN CASES OF CARCINOMA OF THE THORACIC ESOPHAGUS AND CARDIAC END OF THE STOMACH

Selection of Cases for Surgical Intervention.—No patient was refused the benefit of surgical treatment because of age alone. In general, if the condition of the patient seemed good enough to offer reasonable prospect of his survival, an exploratory operation was performed. Obvious evidences of incurability such as the presence of distant metastases or involvement of the liver were taken as contraindications. In carcinoma of the thoracic segment of the esophagus a persistent fever or an intense boring pain in the back, both indicative of deep ulceration and infection, usually indicate that the condition is inoperable, and an operation was not performed in the majority of such cases. A further contraindication in the case of midthoracic lesions is bronchoscopic evidence of invasion of or fixation to the trachea or bronchi.

Resectability.—Of all the cases of carcinoma of the thoracic segment of the esophagus and cardiac end of the stomach which were observed from 1939 to January 1947, 213 were considered to be suitable for operative intervention. Chart 2 summarizes in graphic form the results of treatment in the entire series. Seventy-two lesions were hopeless from the point of view of removal and a resection was not performed. In 141 cases, however, it was possible to remove the growth and perform an esophagogastric anastomosis. Thus the resectability rate of the entire group of 213 cases was 66.2 per cent. A subdivision of the cases according to the level of occurrence of the tumor reveals that there was no significant difference between the low and the high cases with regard to resectability. Of 72 cases of carcinoma involving the midthoracic segment of the esophagus, 22 were inoperable; but a resection was performed in 50 cases, a resectability rate of 69.4 per cent. Furthermore, of the 141 cases of carcinoma of the cardia and lower part of the esophagus, 50 were not resectable and a resection was performed in 91 cases, a resectability rate of 64.5 per cent (table 1).

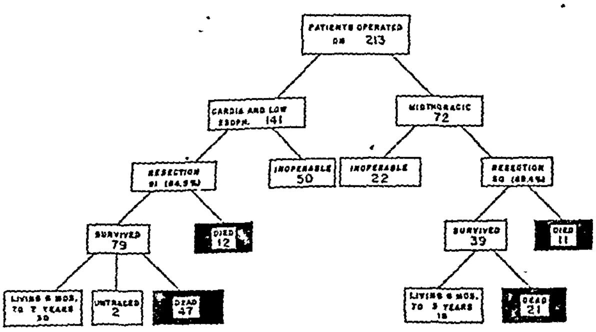

Chart 2.—Summary of results of exploratory operations or resection and primary esophagogastric anastomosis for carcinoma of the esophagus and cardiac end of the stomach. (This does not include 14 cases of carcinoma of the midthoracic esophagus treated by the Torek operation and reported previously.[3b])

Immediate Results of Operation.—Occurrence Rate of Complications and Operative Mortality: Table 2 demonstrates the immediate results of operation and the occurrence rate of complication and operative mortality. Of the 141 patients treated by radical resection and primary anastomosis 93 (66 per cent) made an uncomplicated recovery. Twenty-five other patients (17.7 per cent) in whom complications developed made an ultimate recovery, and 23 (16.3 per cent) died as a result of complications during the early postoperative period.

---

[4] (a) Sweet, R. H.: Transthoracic Gastrectomy and Esophagectomy for Carcinoma of the Stomach and Esophagus, Clinics 3: 1288, 1945; (b) footnote 3b.

[5] Dr. E. B. Bland, physician at the Massachusetts General Hospital, assisted in the management of the cardiac problems in these cases.

Because of the considerably greater magnitude and seriousness of this operative procedure when it is applied to cases in which the growth lies in the midthoracic segment, as compared to that for lesions at the cardia, it is important to differentiate between the two groups, as will be apparent from a further consideration of the data presented in table 2. Thus of the 91 cases of carcinoma at the cardia, which requires a less serious operation than that necessary for the midthoracic group of lesions, 62 (68 per cent) resulted in an uncomplicated recovery. The recovery, though complete, was attended by complications in 17 cases (18.7 per cent) and in 12 cases (13.2 per cent) the complications resulted in death. In contrast to this, of the 50 cases of operation for carcinoma in the midthoracic segment of the esophagus, 31 (62 per cent) resulted in an uneventful recovery. In 8 cases (16 per cent) the convalescence was attended by complications but the patient recovered. In 11 cases (22 per cent), however, the complications were of such severity that the patient died.

Table 1.—*Resectability Rate in All Cases of Carcinoma of the Esophagus and Cardia Chosen for Surgical Intervention*

Location	Total Cases	Exploration Only	Resection	Resectability, %
Carcinoma of the midthoracic esophagus	72	22	50	69.4
Carcinoma of the cardia and lower esophagus	141	50	91	64.5
Total	213	72	141	66.2

Further analysis of the complication and mortality rates occurring in cases of operation for carcinoma located in the midthoracic segment of the esophagus reveals that the incidence of complications and the frequency of postoperative mortality is considerably greater in those cases in which a supra-aortic arch anastomosis is required than in those in which the anastomosis can be performed just below the arch. There were 21 cases of anastomosis just beneath the aortic arch, in 15 (71 per cent) of which the patient made an uncomplicated recovery; in 2 cases (9.5 per cent) complications developed but the patient recovered, and 4 patients (19 per cent) died as a result of postoperative complications. On the other hand, of the 29 cases of supra-aortic arch anastomosis only 16 (55 per cent) resulted in an uncomplicated recovery; in 6 patients (21 per cent) there developed complications, although they recovered, and 7 patients (24 per cent) died of complications. These data are presented in table 3.

ANALYSIS OF THE COMPLICATIONS OCCURRING AFTER RESECTION

Principal Complications.—Table 4 gives a list of the principal complications after resection which were recognized either clinically or as a result of postmortem examination. They are arranged according to the location of the lesion and the type of operation which was performed and include all complications previously reported[6] in addition to those which have occurred in the cases which have been added since those reports were made. It is important to emphasize once again the fact that in some cases two or more complications were observed, so that the sum of all complications is greater than the total number of complicated cases.

Table 2.—*Complications and Mortality Rate in All Patients with Carcinoma of the Esophagus and Cardia Treated by Resection with Esophagogastric Anastomosis*

Type of Operation	No. of Patients	Recovery: Uncomplicated	Recovery: Complicated	Deaths	Mortality, %
Esophagectomy for carcinoma of midthoracic esophagus	50	31	8	11	22.0
Partial gastrectomy and esophagectomy for carcinoma invading the cardia	91	62	17	12	13.2
Total	141	93	25	23	16.3

Manifestations of Infection.—There has been a relative decrease in the number of infections which have occurred since penicillin has become available for routine use, with almost complete disappearance in the low and infra-aortic anastomosis groups. Sepsis is still a factor to be reckoned with, however, in the supra-aortic anastomosis group. In 3 of this group of cases empyema developed. In 2 instances a small pocket of pus developed in the superior aspect of the chest; these were recognized only at autopsy. In 1 case (to be described later) the infection resulted from a leakage at the suture line and was a part of the widespread sepsis which was the cause of the patient's death. In the other the empyema was an insignificant observation in a patient who died of cardiac failure. In the third case there developed bilateral basal empyema accumulations, which were drained successfully by bilateral resection of ribs.

Mediastinitis.—Only 1 case of mediastinitis was observed in addition to those reported previously. This occurred in the patient in whom sepsis developed as a result of leakage at the anastomosis.

Table 3.—*Carcinoma of the Midthoracic Esophagus: Complication and Mortality Rates According to the Type of Operation*

Type of Operation	No. of Patients	Recovery: Uncomplicated	Recovery: Complicated	Deaths	Mortality, %
Esophagectomy with anastomosis below the aortic arch	21	15	2	4	19.0
Esophagectomy with anastomosis above the aortic arch	29	16	6	7	24.1
Total	50	31	8	11	22.0

Cardiac Disorders.—Since the relative decrease in the occurrence of complications which result from infection and as a result of the greater use of the supra-aortic type of anastomosis for high growths in the midthoracic

---

6. (*a*) Sweet, R. H.: Transthoracic Resection of the Esophagus and Stomach for Carcinoma: Analysis of the Postoperative Complications; Causes of Death, and Late Results of Operation, Ann. Surg. **121**: 272, 1945; (*b*) footnote 3b.

segment of the esophagus, cardiac disorders have come to occupy the place of greatest numeric importance in the list of complications after resection. The relatively larger number of cases of myocardial infarction, congestive failure and cardiac arrhythmia which were observed in the patients who had carcinoma of the midthoracic esophagus as compared with those whose growth was at the cardia is obvious from table 4. This is especially true of those in whom it was necessary to dissect the growth out from beneath the aortic arch for the performance of a supra-aortic arch anastomosis. In 91 cases of low intrathoracic anastomosis there were 15 cardiac complications (16 per cent). In the 21 cases of high subaortic arch anastomosis there were 6 such complications (28 per cent), and in the 29 cases of supra-aortic arch anastomosis there were 12 cardiac complications (41 per cent). This difference is not unanticipated in view of the fact that the higher the tumor lies, the more extensive the dissection necessary in the mediastinum; moreover, the duration of the operative procedure is considerably prolonged.

Leakage from anastomosis.	1	0	1	2
Surgical shock..............	0	0	1	1

Pulmonary Complications.—Pulmonary complications have been observed at about the same rate as previously reported. Two additional cases of pulmonary embolism have been observed. This makes 3 cases in 141 operations, an incidence which is rather high but not inconsistent with the advanced age and poor general condition of the majority of these patients.

Vascular Disorders.—Included among vascular disorders are a case of thrombosis of the splenic vein discovered at autopsy and 4 cases of thrombophlebitis of the veins of the leg. The latter were treated by ligation and interruption of the superficial femoral veins.

Miscellaneous Complications.—Miscellaneous complications include 1 case of uremia, 2 of chylous hydrothorax (previously reported[3b]), 2 of acute parotitis, 1 of transitory surgical shock and 2 of leakage from the anastomosis. One case of leakage occurred in an elderly man who had a resection for carcinoma of the cardia with a low intrathoracic anastomosis. It was characterized by the the transitory discharge of gastric contents through the intercostal drainage sinus. Spontaneous closure took place after a few days. In the second case the leakage was the cause of the patient's death. It resulted from technical difficulties in the performance of a supra-aortic arch anastomosis in an elderly woman who had an anomalous right innominate artery which arose from the aortic arch at its junction with the descending aorta. The presence of this large vessel at the place where the proximal segment of the esophagus had to be pulled out from beneath the aortic arch made it practically impossible to perform a satisfactory anastomosis, and leakage occurred.

Note: Thirty patients were operated on three or more years ago. Seven died immediately postoperatively. Of the remaining 23, 9 are living and apparently well at the end of three years, making a three year survival rate of 39 per cent.

CAUSES OF DEATH AFTER OPERATION

Table 5 lists the causes of death which occurred during the early postoperative period, arranged according to the type of operation performed. The most frequent single cause of death was congestive failure of the heart, which accounted for 9 of the 23 fatalities The relative importance of this cause among the cases of high midthoracic carcinoma with supra-aortic anastomosis is manifest. The next most frequent cause of death was sepsis, which occurred in 5 cases. In the remainder of the cases the causes were distributed widely, as follows: pulmonary embolism 1; pneumonia 1; massive pulmonary atelectasis 1; chylous hydrothorax 2; infarction of the liver 1; uremia 1, and myocardial infarction 2.

LATE RESULTS OF RESECTION

Enough time has now elapsed since the performance of the operation in many of the cases that a two year or longer period of observation is possible. Of the 141 patients on whom a resection was performed, 23 died in the hospital. The records of the 118 survivors are available for study. A successful follow-up study has been made in 116 of these cases. Two patients remain untraced and for the purpose of this study are considered as dead as of the last date on which they were known to be living

Table 7.—*Survival After Resection of Carcinoma of the Midthoracic Esophagus*

	1944	1945	1946	Total	% of Those Who Had the Opportunity to Survive a Given Time
Total no. of operations.	12	19	19	50	
Hospital deaths.........	4	3	4	11	
Total analyzed..........	8	16	15	39	
Survivals					
6 months...........	6	11	13	30	77.0
12 months...........	4	8	..	12	50.0
18 months...........	3	2	..	5	31.0
24 months...........	3	..	..	3	37.5

Although the ultimate results will probably be similar, it is desirable at the present time to separate the cases of carcinoma of the midthoracic segment from those at the cardia because there are so few of the former group of cases in which the results of operation have been observed longer than two years and none longer than three years.

SURVIVAL FOLLOWING RESECTION FOR CARCINOMA OF THE LOWER ESOPHAGUS AND CARDIAC END OF THE STOMACH

Table 6 outlines the facts regarding the survival of 91 patients operated on for carcinoma of the lower part of the esophagus and cardia. For each year, beginning with 1939 and ending with 1946, are shown the total number of patients operated on, the number of deaths in the hospital, the total survivors per year and the number of patients alive at given periods of time after operation, starting with six months and ending with the number of years which have elapsed between the year the operations were performed and the last day of 1946.

A study of this table reveals that the majority of fatalities from metastases or recurrence of the disease occur during the first two years after operation. It will be seen also that an appreciable number of patients have survived for more than two years. The three year survival rate in this series is particularly interesting. The table shows that there were 30 patients whose operation was performed three or more years ago. Seven of these patients died as a result of operation, leaving 23 who had an opportunity to survive. Nine of these 23 patients were alive three or more years after operation. This represents a three year survival rate of 39 per cent. A further inspection of the table reveals that of these 9 patients 4 are alive three years, 2 four years, 2 five years and 1 seven years after surgical intervention.

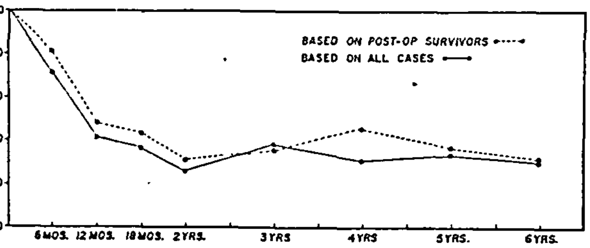

Chart 3.—Graphic representation of yearly survival rate (the per cent of those who had the opportunity to survive a given period) following resection and esophagogastric anastomosis in 91 cases of carcinoma of the cardia. Seventy-nine patients survived the operation.

A graphic representation of the percentage survival each year is shown in chart 3. One line on this chart shows the percentages of survivors following resection excluding the patients who died in the hospital immediately after the operation. For the sake of comparison, another line gives the percentages of survivors based on the entire series of patients undergoing operation, not excluding the postoperative fatalities.

These results give reason for considerable encouragement. They suggest that as with carcinoma in other organs of the body, the majority of deaths from recurrence and metastasis after resection of carcinoma of the esophagus and cardia occur during the first two years after the operation. Furthermore, if the patient survives three years his chances of further survival and possibly of cure are reasonably good (chart 3, table 6). Such a result has not been obtained by any other method of treatment of this disease.

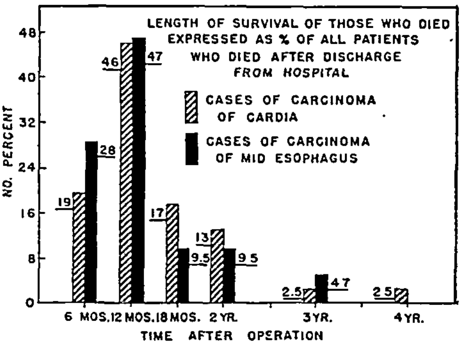

Chart 4.—*Duration of life among those patients who died following discharge from the hospital.*

SURVIVAL FOLLOWING RESECTION OF CARCINOMA OF THE MIDTHORACIC ESOPHAGUS

Holmes and Schulz [7] have shown that no patient with carcinoma of the esophagus treated by supervoltage roentgen radiation survived longer than two years. This is not much different from the survival figures of

---

[7] Holmes, G. W., and Schulz, M. D.: Supervoltage Radiation: A Review of the Cases Treated During an Eight Year Period (1937-1944), Am. J. Roentgenol. **55**: 533, 1946.

Nathanson and Welch,[8] who have indicated that in untreated cases almost all patients are dead less than two years after the onset of the first symptoms.

In the study of the late results of resection in cases of carcinoma of the midthoracic esophagus, it must be remembered that the first patient in this group was treated in 1944. Although not enough time has elapsed, therefore, to make studies of the end result in this group particularly significant, table 7 serves to reveal the same tendencies as are seen in table 6, which deals with carcinoma of the lower segment of the esophagus. The large number of deaths occurring in the first twelve months is apparent, and the percentage survivals at six months, one year, eighteen months and two years after operation are similar to those of the other group. Subsequent reports will be made regarding these cases after sufficient time has elapsed.

VALUE OF THE OPERATION IN THE PALLIATION OF THE DISEASE

In carcinoma of the esophagus the most distressing symptom is dysphagia. The misery attendant on the almost complete obstruction which ultimately afflicts patients who have the disease is pathetic to observe. Any method of treatment which will alleviate this distressing symptom is gratefully received. Bougienage and roentgen radiation are notoriously ineffectual except to afford transitory periods of relief in a few cases. It has been a gratifying observation that even n those who die of recurrent or metastatic disease folowing resection with esophagogastric anastomosis there seldom develops a recurrence at the anastomotic stoma. This fact alone makes the operation worth while if the patient can thus be kept comfortable for a period of at least six months to one year.

The duration of palliation obtained by the use of this surgical procedure in cases of carcinoma of the esophagus and cardia varied from six months to four years. In the group of cases of carcinoma of the cardia, of the 46 patients who died subsequent to the operation 9 lived six months or less, 21 lived six months to one year, 8 lived twelve to eighteen months, 6 lived two years, 1 lived three years and 1 lived four years. In the group of cases of carcinoma of the midthoracic segment of the esophagus, of those who died subsequent to the operation 6 lived six months or less, 10 lived from six months to one year, 2 lived twelve to eighteen months, 2 lived two years and 1 lived three years. Chart 4 illustrates the relative length of survival in each group of cases of those patients who died subsequent to their discharge from the hospital. Because the total numbers are so different in the two groups, the length of survival is shown in each category as a percentage of the total number of deaths in that group.

As a method of palliation alone, therefore, resection and anastomosis has been proved superior to any other form of treatment yet available in the management of carcinoma of the esophagus and cardiac end of the stomach. The significant fact, however, is that many patients survive longer than a year; in some the relief from dysphagia produced by resection and esophagogastric anastomosis has been prolonged for two years or more.

ABSTRACT OF DISCUSSION

Dr. Dallas B. Phemister, Chicago: Dr. Sweet is to be congratulated on the superb operative results and on the excellent studies that he has made on the patients. The encouraging aspect of this field of surgical practice is the rapid decline in operative mortality and the extension of the field of operability to include high lesions in the esophagus and advanced lesions of the stomach, sometimes adherent to surrounding structures which must also be excised.

At first the mortality was extremely high both in Japan, where resection by thoracolaparotomy was first performed, and in this country, where transthoracic resection was first done successfully. The mortality has so declined that in experienced hands it now ranges around 15 per cent. In the last 26 operations that Dr. Adams and I have performed there were but 2 operative deaths. A discouraging aspect is that the incidence of recurrence after operation has not improved to the same extent that the operative mortality has been reduced. The frequency of recurrence varies with the location of the tumor. The most favorable location is in the lower end of the esophagus. Tumors of the esophagus narrow the lumen and produce obstructive symptoms relatively early, from which the diagnosis is sooner or later made. Metastases are commonly present by the time the patient receives operative treatment. The early metastases from carcinoma of the lower esophagus are usually located in the lymph nodes along the upper part of the lesser curvature of the stomach which are removable. This makes for a better prognosis in carcinoma of the lower esophagus. Dr. Sweet referred to the first successful one stage transthoracic resection and anastomosis, done by Dr. Adams and myself. The tumor was in this location and lymph node metastases in the lesser curvature of the stomach were removed. The patient is now well nine and one-half years after operation. Recurrence is more frequent after operation for carcinoma of the upper part of the esophagus because the neoplastic growth invades surrounding structures and metastasizes to regional lymph nodes that are difficult or impossible to remove. Carcinoma of the proximal stomach usually begins at a distance from the esophageal opening and may grow silently for as long as nine to eighteen months before it finally reaches the esophagus, produces obstructive symptoms and gets diagnosed. By that time it has often spread to surrounding structures and metastasized to regional lymph nodes, which makes for a high incidence of recurrence after resection. Early diagnosis and early surgical operation are the keynotes for future improvement.

Dr. Morris T. Friedell, Chicago: What portion of the vagus nerves is resected in Dr. Sweet's operation, and does this result in any disturbance of gastric motility?

Dr. Richard H. Sweet, Boston: The work of Dr. Phemister has always been a great stimulus to me. In this transthoracic operation, extremely long sections of the vagus nerve are resected, and I have come to disregard the vagus nerve so thoroughly in dealing with these carcinomas of the esophagus that I pay little attention to it. The nerve is usually divided just below the aortic arch, often above the pulmonary branches. It is not divided above the origin of the recurrent nerve, however. I would like to comment on something which causes concern to the thoracic surgeon, namely, that I have never been aware of any vago-vagal reflex in man while handling the vagus nerve during these operations. The motility of the stomach is of course interfered with, and yet there is something peculiar about that observation, because the roentgenologists at Massachusetts General Hospital have commented without any prompting whatever that the lack of gastric motility, about which the surgeon used to be so concerned, seems to be less and less obvious as time goes on. Why that should be, I do not know, except that the amount of dissection which I now do toward the antrum and the duodenal end is much greater than it used to be.

STREPTOMYCIN IN OCULAR INFECTIONS

JOHN G. BELLOWS, M.D.
and
CHESTER J. FARMER
Chicago

The adoption of streptomycin for the treatment of various infections caused by organisms either insensitive or resistant to sulfonamide compounds and penicillin has aroused much interest among ophthalmologists. Streptomycin has been shown by in vitro and in vivo experiments to be bacteriostatic against certain gram-positive organisms as well as against a wide variety of hitherto resistant gram-negative forms.

The literature on the use of streptomycin in ocular infections is extremely meager. Owens[1] reported 1 case of a severe corneal infection caused by Escherichia coli, which responded satisfactorily to the local application of streptomycin. Alberstadt and Price[2] treated 9 patients with corneal infections with streptomycin applied locally. In spite of the fact that adequate bacteriologic data were unobtainable, they concluded that the addition of this antibiotic to the usual form of treatment definitely shortened the healing time.

Experiments undertaken by Leopold and Nichols[3] have demonstrated that streptomycin appears in the conjunctiva, sclera, extraocular muscles and aqueous humor of rabbits when it is administered in systemic dosages of 10,000 micrograms per kilogram of body weight. In order that streptomycin might appear in detectable amounts in the cornea, vitreous, chorioretinal tissues and optic nerve, 100,000 micrograms per kilogram of body weight were required. These huge systemic dosages, which were required to obtain a detectable but probably therapeutically inadequate level in these tissues, might under prolonged treatment produce neurotoxic disturbances in man. Fortunately for the ophthalmologist high concentrations of streptomycin in the conjunctival sac may be instantaneously achieved by simple instillation. Furthermore, satisfactory concentrations are readily obtained in the aqueous in the presence of abraded or inflamed corneas and may be obtained even in the presence of an intact cornea if a wetting agent or iontophoresis is employed.[4] Even in the vitreous high concentrations may be safely achieved by the injection of amounts up to 500 micrograms of streptomycin in 0.1 cc. isotonic sodium chloride solution.[4a]

The purpose of this paper is to present results of streptomycin therapy in experimental and clinical ocular infections.

I. THE EFFECTIVENESS OF STREPTOMYCIN THERAPY IN EXPERIMENTAL OCULAR INFECTIONS WITH CERTAIN ORGANISMS

A. Treatment of Experimental Corneal Ulcer Due to Bacillus Pyocyaneus.—Up to recent times the treatment for clinical or experimental ulcer of the cornea due to Bacillus pyocyaneus has been unsatisfactory. Sulfapyridine administered orally to the experimental animal has been ineffective prophylactically, causing only a decrease in the severity of the infection.[5] When sodium sulfacetamide was used locally as a prophylactic agent,[6] the administration of it in one hour prevented 11 of 17 infections; after 5 hours, 5 of 12, and after 12 hours, only 2 of 12. Von Sallmann,[7] employing the same organism and sulfadiazine administered orally and locally by means of iontophoresis, was successful in preventing infection in 90 per cent of the inoculated animals.

Experiments were undertaken to determine the effectiveness of streptomycin in similarly produced corneal ulcers. The strain of B. pyocyaneus used was one which produced uniform infections of the cornea in rabbits. In a series of normal rabbits anesthetized by intravenous injections of pentobarbital sodium, an area of each cornea was delineated by a 4 mm. trephine and the epithelium within this area was abraded by a knife. Fluorescein was employed to determine the completeness of abrasion, after which a cotton applicator moistened in a twenty-four hour broth culture of B. pyocyaneus was forcibly rubbed against the abraded area of both eyes for sixty seconds.

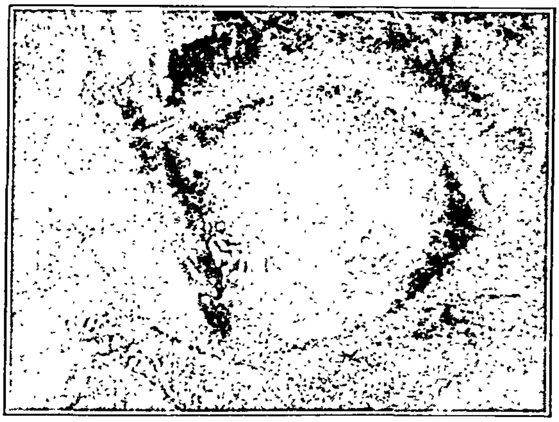

Fig. 1.—Pyocyaneus infection of cornea untreated.

Streptomycin was applied to the right eye at two, four, six, eight and twenty-four hours after inoculation, while the left eye was reserved as an untreated control. Treatment consisted of three instillations of an isotonic sodium chloride solution containing 10,000 micrograms of streptomycin per cubic centimeter at two hour intervals after the periods previously indicated.

Our experiments demonstrated that streptomycin therapy, when applied within six hours, in all cases prevented infection of the cornea. The control eyes uniformly progressed to complete destruction of the cornea. These results indicate the great value of streptomycin against B. pyocyaneus in infections of the cornea. Up to the present time, streptomycin is unexcelled as a therapeutic agent in this type of infection (figs. 1 and 2).

B. Treatment of Experimental Streptococcic Infection of Vitreous.—Attempts to prevent or influence experimental infections of the vitreous had been unsuc-

cessful until von Sallmann and his co-workers[8] and Leopold[9] were able to check the progress of a hemolytic Staphylococcus aureus infection and Klebsiella pneumoniae type III infection by means of the intravitreous injection of penicillin. The present experiment was to determine the effectiveness of streptomycin therapy with experimental beta-hemolytic streptococcic infection of the vitreous. For this purpose the vitreous of each eye of a series of rabbits was inoculated with 0.1 cc. of a twenty-four hour broth culture of Streptococcus pyogenes strain C 203 diluted to 1 : 10,000 in isotonic sodium chloride solution (plate count 1,000 to 2,000 organisms per cubic centimeter). This organism was observed to be sensitive to 10 micrograms of streptomycin in 1 cc. of solution.

These rabbits were treated either systemically or by injection of streptomycin into the vitreous. The systemic administration was in the form of (1) continuous intravenous drip of 100,000 micrograms of streptomycin solution per kilogram of body weight over a period of six hours or (2) intramuscular injection of a similar amount of the agent emulsified in a sterile preparation of cholesterol derivatives in peanut oil with 2 per cent beeswax ("pendil improved"); the drug was given either as a prophylactic or therapeutic measure. The intravitreal injections of streptomycin were administered either simultaneously or two, four, six, eight or twenty-four hours after the inoculation. For intravitreous injection 0.1 cc. of an isotonic solution of sodium chloride containing 250 to 1,000 micrograms of streptomycin per cubic centimeter was used

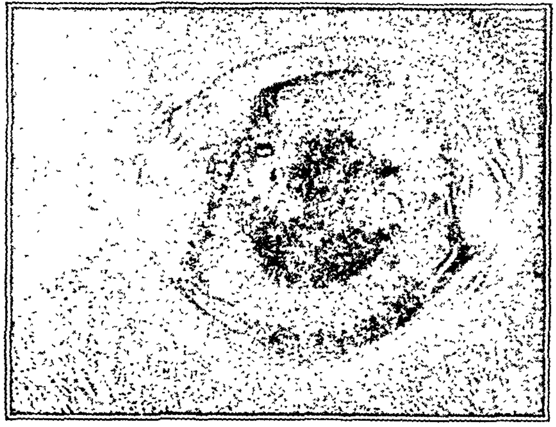

Fig. 2.—Pyocyaneous infection of cornea treated with streptomycin.

In these experiments neither form of systemically administered streptomycin prevented the development of a vitreous abscess. However, the external inflammatory manifestations were far less pronounced in the systemically treated animals than in untreated controls. Animals receiving intravitreous injections of 100 to 200 micrograms of the less purified streptomycin, or as little as 25 micrograms of the streptomycin–calcium chloride complex did not develop a vitreous abscess if treated within six to eight hours after the inoculation. On the other hand, vitreous infection resulting in eventual abscess occurred in the untreated control eye or in those treated with less than the previously specified amounts of streptomycin (fig. 3).

As noted by Leopold and Nichols, streptomycin enters the vitreous with difficulty. Concentrations of but 2 units of the agent per gram of vitreous could be obtained following a single intramuscular injection of 100,000 units of streptomycin per kilogram of body weight. Since the in vitro sensitivity of the organism employed by us was shown to be 10 micrograms per cubic centimeter, it is easy to understand why the systemic administration of the antibiotic was ineffective. The observed higher concentrations reported by Leopold and Nichols as occurring in the conjunctiva, sclera, extraocular muscles and aqueous humor explains the localization of the infection to the vitreous. On the other hand, the direct intravitreal injection of streptomycin in the concentrations and within the time indicated effectively prevents infection. Our experimental results parallel those of Leopold and of von Sallmann, who demonstrated that vitreous infection with staphylococci or pneumococci were arrested if intravitreal injections of penicillin were made within eight hours after inoculation.

II. THE CLINICAL APPLICATION OF STREPTOMYCIN IN OCULAR INFECTIONS

In 23 cases of ocular infections treated with streptomycin, 7 were acute conjunctivitis, 10 were chronic conjunctivitis, 5 were corneal infections and 1 was a postoperative intraocular infection.

A. Acute Conjunctivitis.—The 7 cases of acute conjunctivitis included 1 primary meningococcic conjunctivitis, the organism being identified as Neisseria intracellularis group IIa. There was 1 patient with almost a pure culture of Bacillus subtilis and another with a pure culture of diphtheroids. Hemolytic staphylococcus albus and alpha hemolytic streptococci were found in 1 case; hemolytic Staph. albus alone in 1 case, and hemolytic Staph. albus with diphtheroids in another. In 1 patient cultures and smears were negative. The general procedure for all patients was to give streptomycin drops (10,000 micrograms per cubic centimeter) at one hour intervals during the waking hours (eight to nine applications a day) and to continue the treatment for eight days.

The meningococcic conjunctivitis improved in twenty-four hours, and the eye appeared normal at the end of four days (figs. 4 and 5). The infection due to B. subtilis showed improvement in forty-eight hours, and the redness was entirely gone by the seventh day. The conjunctiva from which the pure culture of diphtheroids was obtained was greatly improved by the third day and entirely well on the seventh day. In the case in which there was a mixed infection due to hemolytic Staph. albus and alpha hemolytic streptococcus, improvement was evident in forty-eight hours. The patient in whom infection was due to hemolytic Staph. albus alone recovered completely by the seventh day, and the patient with acute conjunctivitis in which no organisms were isolated recovered on the fourth day.

B. Chronic Conjunctivitis.—There were 10 cases of chronic conjunctivitis. The duration of the disease prior to streptomycin therapy varied from one month to several years. In 3 of these the smears and cultures were negative, and treatment with streptomycin produced no noticeable change in symptoms. In 1 case there was a chalazion associated with a decided conjunctival inflammation of both the upper and the lower lids. Culture from the conjunctiva revealed two colonies of hemolytic Staph. aureus, three colonies of alpha Strep. fecalis and five colonies of diphtheroids. Streptomycin drops, although causing the conjunctival sac to become sterile, produced no appreciable improvement in the appearance of the eye in eight days. In another patient hemolytic staphylococci and diphtheroids were found. After forty-eight hours of therapy a culture from the conjunctiva was negative. There was pronounced improvement both objectively and subjectively. Treatment was continued for eight days. However, three weeks after the cessation of treatment there was a recurrence of symptoms. In 1 case pneumococci were found. After six days of streptomycin therapy cultures from the conjunctivas became negative. However, the conjunctivas remained red and the discomfort continued even after ten days of therapy, after which treatment was discontinued. In a chronic case of fifteen years' duration, a culture of material from the right eye exhibited the growth of one colony of coagulase-negative Staph. aureus, while that from the left produced eight colonies. After three days of streptomycin therapy cultures exhibited no growth and subjective symptoms were improved. However, the palpebral conjunctivas were still hyperemic even after ten days of treatment. A smear taken from another patient revealed a single gram negative extracellular organism, but the cultures were negative. Streptomycin therapy was stopped after forty-eight hours because the patient stated that the treatment "made the eye feel and look worse."

[9] Leopold, I. H.: Intravitreal Penetration of Penicillin and Penicillin Therapy of Infections of the Vitreous, Arch. Ophth. **33**: 211-216 (March) 1945.

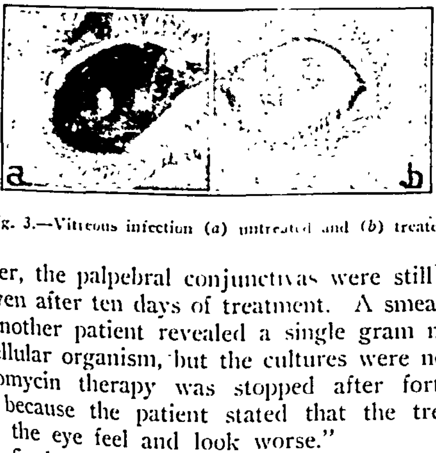

Fig. 3.—Vitreous infection (a) untreated and (b) treated.

The final test of the clinical application of streptomycin was in a patient with myotonic dystrophy with typical cataracts. He had suffered from chronic conjunctivitis for many years. There were scars in the palpebral conjunctivas of the two upper lids and in the vessels in the corneas. Conjunctival scrapings which were dyed with Giemsa's stain failed to reveal any inclusion bodies. Cultures were negative. Local streptomycin therapy caused a decided decrease in the conjunctival congestion and secretion within seven days.

C. Corneal Infections.—There were 5 cases of corneal disease. One patient had corneal infection which, despite treatment for three months with fever therapy, sulfonamide drugs, penicillin and delimiting keratotomy, continued to progress. Before local streptomycin therapy was instituted smears and cultures were taken from the ulcer. These failed to exhibit the growth of any organisms. Within five days the cornea no longer stained with fluorescein, the margins of the lesions became more distinct and there was a pronounced decrease in the generalized congestion.

The second case was that of a white man aged 40, who was in a poor state of general nutrition. There was a slowly progressive corneal infiltration of the left eye accompanied by exudates in the anterior chamber. His previous treatment had consisted in attempts to improve the general nutrition and local treatment in the form of atropine, sulfonamide compounds, penicillin by drops and iontophoresis and delimiting keratotomy. Cultures taken prior to streptomycin therapy revealed ten colonies of diphtheroids and forty colonies of a gram-negative rod. Local streptomycin therapy for ten days did not change the course of the disease.

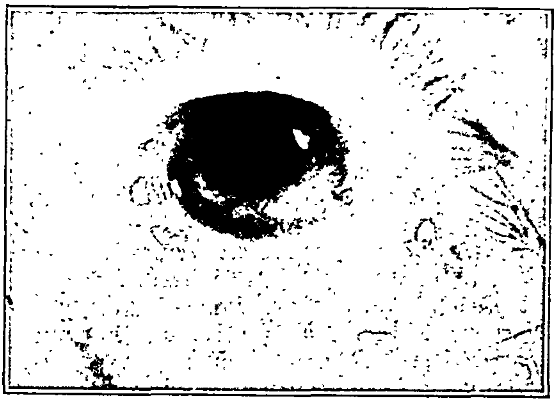

Fig. 4.—Meningococcic conjunctivitis before treatment.

The third corneal infection was a long standing, active, tuberculous keratitis having characteristics of both phlyctenular and interstitial types. Atropine therapy and tuberculin desensitization had been without effect. Streptomycin was administered in the form of drops and iontophoresis without apparent improvement in ten days, at which time treatment was discontinued.

In the fourth case a Negro man had a deep grayish white infiltrate in the cornea. Four days of fever therapy and local instillations of atropine failed to stop the progress of the disease. A culture taken from the cornea at this time revealed twenty colonies of hemolytic Staph. albus and one hundred and thirty colonies of diphtheroids. Streptomycin in the form of drops was administered at two hour intervals. A definite improvement was noticed in forty-eight hours.

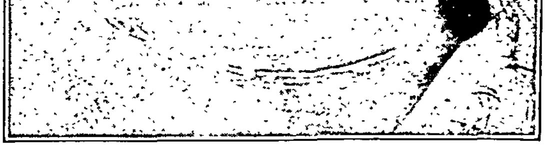

Fig. 5.—Meningococcic conjunctivitis after four days of streptomycin therapy.

The fifth patient was admitted to the hospital on the service of Dr. I. Puntenney. There was a severe rapidly progressive pyocyaneus infection of the cornea, which had been unresponsive to sulfonamide drugs. At the beginning of the third day of the infection 2 or 3 drops of the solution of streptomycin were instilled into the infected eye every thirty minutes during the waking hours and every two hours at night. Any further spread of the corneal lesion was blocked by the use of streptomycin, and a pronounced improvement in the appearance of the eyeball was evident at the end of forty-eight hours. The redness disappeared at the end of the seventh day.

D. Intraocular Infection.—A Japanese patient on Dr. B. Cushman's service was seen on the second postoperative day after an intracapsular extraction. Examination revealed a well defined conjunctival congestion, but the cornea was fairly clear. In the pupillary area a yellowish gray exudate was present. Cultures revealed a hemolytic Staph. aureus. It was recommended that penicillin and streptomycin be administered by means of iontophoresis. On the fourth day 1,000 Oxford units of penicillin and 500 micrograms of streptomycin were injected into the anterior chamber. The course of the infection was not influenced by these antibiotics.

COMMENT

In the evaluation of streptomycin therapy the rapidity of improvement must be considered in both acute and chronic ocular infections. In acute infections if the period of morbidity under streptomycin therapy is constantly less than that observed in treatment by earlier conventional methods, it may be assumed that the drug was responsible for this favorable effect. In chronic infections which have resisted other forms of therapy, if rapid improvement follows the use of streptomycin it is at least suggestive that the improvement is attributable to this agent. Ideally, observations on the therapeutic effectiveness of a new agent should be based on cases of bilateral infection which permit adequate controls, the more severely infected eye receiving the therapeutic agent while the other receives an equal amount of the vehicle. This was attempted in 2 of the cases reported herein without significant results.

The use of streptomycin instead of penicillin in certain infectious due to organisms known to be sensitive to penicillin is justified on the basis of Robinson's[10] *observations and of our determination of the sensitivity* of the organisms. Furthermore, it would be valuable to be able to use another drug in the treatment of those persons who are hypersensitive to penicillin in cases in which the organism has acquired a resistance to penicillin, or in combination with penicillin in some instances of mixed infections.

As anticipated from Robinson's in vitro experiments, which demonstrated the high degree of sensitivity of the meningococcus to streptomycin, the acute meningococcic conjunctivitis responded rapidly to treatment with this antibiotic. The improvement noted in the other 6 cases of acute conjunctivitis produced by a variety of organisms indicates that streptomycin may be useful in the treatment of some forms of this disease. However, the value of this antibiotic cannot be definitely established until many more instances have been observed, particularly in cases of bilateral infection with adequate controls established by the procedure previously suggested.

In all 6 cases of chronic conjunctivitis in which organisms were found in the conjunctivas just prior to streptomycin therapy, the cultures became sterile a few days later. However, the clinical appearance in some instances was unchanged, suggesting that other than bacterial causes were active in continuing the inflammation. Streptomycin exerted a favorable influence in the case of chronic conjunctivitis with the clinical characteristics of trachoma.

In our animal experiments streptomycin was found to be completely effective in the prevention of corneal infections due to B. pyocyaneus if used within six hours. Its value in this disease has been further established by our clinical observations in the case of B. pyocyaneus infection of the cornea of forty-eight hours' duration which responded promptly to streptomycin. The favorable influence of streptomycin in the rapidly advancing infection of the cornea (fourth case) from which hemolytic Staph. albus and diphtheroids were cultured is also noteworthy. In the slowly advancing corneal ulcer which had progressed in spite of all other forms of treatment it is significant that improvement occurred concomitantly with the initiation of streptomycin therapy.

The failure of streptomycin in the corneal ulcer in which diphtheroids and numerous gram-negative rods were found may be partially explained by the general debilitation of the patient.

Finally, the keratitis which had characteristics of both the phlyctenular and interstitial types also failed to improve, even with intensive streptomycin therapy. If the condition was entirely phlyctenular in nature no improvement could be expected, since this type of keratitis is due to a hypersensitization to tuberculin protein.

Von Sallmann in both clinical and animal studies reported the refractory nature of advanced infections of the vitreous to penicillin. This is also true with streptomycin, for as shown in the early part of this paper no arrest of the infection occurred in rabbits if streptomycin therapy was instituted eight hours after inoculation with the infective organism. This explains the failure of the well established postoperative intraocular infection to respond to antibiotics. However, if postoperative intraocular infections can be recognized within the specified time limits in which the antibiotic is effective, the injection of the agent directly into the eye might arrest the infection and thus save the eye.

From our clinical observations it is evident that many organisms are soon eliminated from the conjunctiva and cornea by repeated instillations of streptomycin solution in the recommended concentrations. In many instances recovery from certain types of acute and chronic external ocular infections will follow the disappearance of the organisms. Relapses occur if treatment is stopped too soon. Inflammatory conditions in which organisms are not isolated cannot be expected to respond to streptomycin therapy, *nor do infectious dis-*

cases in which other contributing factors are present, such as chalazion or general debilitating diseases, respond to streptomycin therapy alone.

SUMMARY

The penetrability of the cornea to streptomycin may be increased by abrasion, inflammation, ion transfer and wetting agents.

Streptomycin is safe and nonirritating to the surface of the eyeball in concentrations up to 10,000 micrograms per cubic centimeter. Higher concentrations delay the regeneration of the epithelium and promote scarring and vascularization of the cornea.

Intraocular injections of 500 micrograms of streptomycin in 0.1 cc. of isotonic sodium chloride solution are well tolerated. However, as little as 25 micrograms of streptomycin is effective in the prevention of experimental beta hemolytic streptococcic infections of the vitreous if the drug is injected within six to eight hours after inoculation.

Experimental corneal infections due to Bacillus pyocyaneus are completely prevented if within six to eight hours after inoculation three instillations of streptomycin drops (10,000 micrograms per cubic centimeter) are made at two hour intervals.

Repeated instillations of 10,000 micrograms of streptomycin in 1 cc. of isotonic sodium chloride solution sterilizes the conjunctival sac in most cases of acute and chronic conjunctivitis.

Clinically streptomycin was employed in 23 cases of ocular infection. In 2 cases it was exceptionally effective, namely, a primary meningococcic conjunctivitis and a B. pyocyaneus infection of the cornea.

There is definite evidence that in most cases both of acute and of chronic infections of the conjunctiva and cornea organisms are rapidly eliminated by streptomycin therapy; in the absence of complicating factors healing follows rapidly in many instances.

ABSTRACT OF DISCUSSION

DR. PARKER HEATH, Detroit: The evaluation of the merits of a new antibiotic in the field of ocular therapy is no easy task. There are certain requisites, such as controlled laboratory testing and extended and versatile clinical investigation. Both of these approaches should be made by open, truth-seeking minds. Dr. Bellows and Dr. Farmer are reporting along these avenues. Their laboratory studies support those of Leopold and Nichols, that effective concentrations of streptomycin in ocular tissue could not be had by practical, systemic application and that local use was effective in the antibiotic range of the drug, local use by topical application and supported by wetting agents, corneal scuffing or iontophoresis as advocated by von Sallmann (10,000 micrograms per cubic centimeter at two hour intervals). In the vitreous, the most effective minimal concentration followed direct injection of 100 to 200 micrograms of the sodium and 2.5 micrograms of the calcium chloride complex. All this is consistent with other reported studies by Leopold and von Sallmann on the use of sulfonamide compounds or penicillin. While the clinical series of the authors is too small to be conclusive, good clinical hints are extractable. Streptomycin seems unusually effective in meningococcic conjunctivitis and keratitis due to Pseudomonas aeruginosa—the latter being based on animal experimentation and 1 human case. Hemolytic Staphylococcus albus and alpha hemolytic Streptococcus were in the range of the drug. Owens and Alberstadt and Price have reported success from local use. The failure of response in active ocular tuberculosis in 1 case is consistent with the experiences of others. The first ray of hope in a chemotherapeutic attack on ocular tuberculosis is that recently reported by Woods, using "promin" (sodium p,p′-diaminodiphenylsulfone-N,N′didextrose sulfonate) and "promizole" (4,2′-diaminophenyl-5′-thiazolylsulfone) in experimental ocular tuberculosis in immune allergic rabbits. Bellows and Farmer have reported a single case of postoperative infection which failed to yield to both iontophoresis and streptomycin on the second day and injections into the anterior chamber on the fourth day. This is not conclusive, because of the lateness of the treatment. Ophthalmic surgery has a low incidence of postoperative infection. But the complication is a probability which no one can completely deny. The authors have shown early effective concentration to be necessary. This is in support of my practice of inspecting eyes after intraocular surgical treatment within twenty-four hours. In my experience, the complications from systemic use of streptomycin are real—those from local use are not so significant. Locally there is delayed epithelization of the cornea and some promotion of scar. A confusing probability is that of adaptability of the infectious organism to streptomycin.

DR. IRVING H. LEOPOLD, Chicago: For many years Dr. Bellows and his associates have contributed substantially to our knowledge of the new chemotherapeutic agents. He has studied both experimentally and clinically numerous sulfonamide compounds, penicillin and now streptomycin. He is therefore in an excellent position to evaluate carefully any new anti-infectious agent. The evidence accumulated by Dr. Bellows and Dr. Farmer seems to favor the local methods of applying streptomycin over systemic administration for many types of ocular infections. Conjunctivitis, keratitis and infections of the vitreous are examples. There are many reasons for this. Systematically administered streptomycin is not free of toxic properties. Monkeys receiving injections of 50 to 100 mg. per kilogram of body weight showed a peculiar type of fatty infiltration of the kidneys and of the liver. The same dose caused proteinuria and some reduction of renal function. Dogs given similar doses occasionally had labyrinthine disturbances, a phenomenon that has also been noted in human beings and probably represents streptomycin's most serious untoward effect. Local tissue toxicity, however, is not pronounced. It is true that application of 1,250 units of streptomycin to the cerebral cortex of cats and monkeys has caused convulsive manifestations in 30 per cent of the animals tested, but these effects were less strong than those produced by comparable amounts of penicillin—as judged by clinical and encephalographic observations. Streptomycin has a low toxicity for spleen in tissue culture and is only mildly inhibitory for fibroplasts and epithelial cells. One of the chief disadvantages of streptomycin is the ease with which organisms develop a resistance to this drug. This is less likely to occur if the concentrations of the streptomycin in the infected tissues are high and maintained. It has been shown that higher concentrations can be obtained in most of the ocular tissues by local administration than by the systemic route. This is certainly the case for the conjunctiva, cornea, anterior chamber, vitreous humor and lens. To recommend local therapy for inflammations of ocular tissues does not mean that the systemic route may not also be successful in some types of ocular infections but simply that systemic therapy is not necessary for ocular infections not associated with systemic disease, may be more dangerous and, in addition, is more expensive, as tremendously greater quantities are required.

DR. JOHN G. BELLOWS, Chicago: I wish to thank Dr. Heath for his interesting remarks. He and Dr. Leopold mentioned that the organisms develop resistance to streptomycin readily. An organism that is at first sensitive to streptomycin may become within twenty-four hours resistant to it. Dr. Leopold has called our attention to the dangers inherent in the systemic use of streptomycin. Hypersensitization is relatively uncommon with the external application of streptomycin. This is indicated by the development of sensitization in only 1 of 30 cases in which this antibiotic was used.

THE CONTROL OF EPILEPSY

An Interim Report on 3-Methyl-5, 5-Phenylethylhydantoin and Phenobarbital Therapy

ANTHONY E. LOSCALZO, M.D.
New York

A preliminary report by me in 1945[1] dealt with a two year study of a new anticonvulsant, 3-methyl-5, 5-phenylethylhydantoin[2] and phenobarbital in a group of patients suffering from epilepsy of unknown or organic etiology. This new drug reduced grand mal seizures approximately 60 per cent, as compared to previous medications with diphenylhydantoin sodium and phenobarbital. It is important to note that phenobarbital was used in combination with both diphenylhydantoin sodium and 3-methyl-5, 5-phenylethylhydantoin, thus assuring a valid comparison of the two drugs. The incidence of side effects with the latter as compared with diphenylhydantoin sodium was strikingly low.

It was suggested in the first report that further investigations were indicated and necessary for more complete evaluation. This interim report is a continuation of the preliminary studies and encompasses an additional eighteen months of observation on the same patients and 51 new patients.

Since the first publication additional experimental data has accumulated. Swinyard and Goodman,[3] studying a group of hydantoinates in rats, introduced two new laboratory technics:

> The toxic dose (*T*) was taken as that just causing observable neurological deficit or other untoward effect. The protective dose (*P*) was that just required to abolish tonic extensor components of maximal electroshock seizures produced by current intensities five times threshold.

In this report by Swinyard and Goodman[3] it was noted that the protective index (*T/P*), which is the ratio of the toxic dose to the protective dose, has a value of 12 for 3-methyl-5, 5-phenylethylhydantoin and 2 for diphenylhydantoin sodium. In the same report it was stated that the percentage change in normal electroshock threshold was plus 27 for 3-methyl-5, 5-phenylethylhydantoin and only plus 2 for diphenylhydantoin sodium.

These authors also observed that the dose (milligram per kilogram intraperitoneally) for protection against maximal electroshock seizures was 5 mg. with 3-methyl-5, 5-phenylethylhydantoin and 50 mg. for diphenylhydantoin sodium.

These data suggest in animals pronounced advantages for 3-methyl-5, 5-phenylethylhydantoin and thus aid in substantiating the clinical observations in these studies up to this time.

CHEMICAL NOTES ON 3-METHYL-5, 5-PHENYLETHYLHYDANTOIN

The structural formulas (figs. 1, 2 and 3) show the close chemical similarity and relationship between some of the most commonly used anticonvulsants, including 3-methyl-5, 5-phenylethylhydantoin, on which this clinical study is based.

Diphenylhydantoin sodium and 3-methyl-5, 5-phenylethylhydantoin are both hydantoin derivatives. They may be considered as derivatives of a cyclic condensation product of urea and acetic acid, whereas phenobarbital is a derivative of the cyclic condensation product of urea and malonic acid.

As to the chemical difference between diphenylhydantoin sodium and 3-methyl-5,5-phenylethylhydantoin, it is noted that one phenyl group of the diphenylhydantoin sodium is replaced by an ethyl group in 3-methyl-5, 5-phenylethylhydantoin; in addition, one hydrogen atom, bound to nitrogen, is replaced by a methyl group in the new drug. Furthermore, diphenylhydantoin sodium is offered in the form of the sodium compound, whereas 3-methyl-5, 5-phenylethylhydantoin is sodium-free and has the chemical characteristics of a weak acid.

CLINICAL STUDIES

Of the 67 cooperative patients studied,[4] 35 were females and 32 males; 16 patients were of the original group reported in the preliminary studies of 1945. Electroencephalograms were performed on 54 patients; pneumoencephalograms on 12, roentgen examination of the skull on 28, and exploratory craniotomy on 5. The Wassermann test, complete blood count, urinalysis and blood chemical studies (dextrose, urea nitrogen and creatinine) were done routinely on all patients. Blood calcium, phosphorus studies, dextrose tolerance tests and basal metabolism determinations were ordered when indicated. All patients were subjected to a complete neuropsychiatric check-up. The history and physical examination forms of the American Epilepsy League are standard in this clinic.

Fig. 2.—"Dilantin sodium," Diphenylhydantoin sodium.
Fig. 3.—Phenobarbital, phenylethylbarbituric acid.

Each patient was seen at the clinic once each week for the first few weeks and then every second week or monthly, depending on the severity and frequency of the attacks. Each patient was instructed to bring in a written record of the date, time and severity of each convulsion as well as a description of any untoward symptoms that were experienced. At each visit these facts were transcribed and further histories taken and physical examinations made when indicated. When patients failed to attend a clinic a postal card was mailed asking them to return. Data on the noncooperative patients are excluded from this study.

The age range of the sixty-seven patients is given in table 1, and the duration of epilepsy in table 2. The duration of treatment with 3-methyl-5, 5-phenylethylhydantoin is shown in table 3. According to the Lennox Classification,[5] the cases fall into one of the groups shown in table 4.

The figures represent the predominant type of seizure in each patient, but all patients, except one traumatic jacksonian, suffered from grand mal and many of the patients, in addition, had petit mal.

The probable etiologic basis for the disease is given in table 5. In the group of 51 cases of undetermined cause are included 5 cases with positive neurologic observations suggestive of chronic degenerative disease, 1 case of chronic alcoholism, 1 case of neurosyphilis (latent) and 1 case of mild manic-depression. This also holds true for some cases in which the electroencephalograms showed possible epileptogenous areas. It might be argued that the etiologic basis was evident in some of these cases, but there were so many controversial points that it was decided to place them in the group of undetermined cause. The 3 cases of cortical degeneration were proved by surgical operation.

PREVIOUS MEDICATION

Fifty-five patients had been taking diphenylhydantoin sodium in varying amounts; most of them were taking 3 capsules, 0.3 Gm. (4.5 grains) to 5 capsules, 0.5 Gm. (7.5 grains) per day, the highest being 0.6 Gm. (9 grains) per day. Fifty of the 55 had been taking the diphenylhydantoin sodium in combination with phenobarbital; 8 of them had been receiving 0.03 to 0.06 Gm. (½ to 1 grain) of phenobarbital daily; 11, over 0.06 Gm. (1 grain) to 0.1 Gm. (1½ grains) daily; 23, over 0.1 Gm. (1½ grains) to 0.13 Gm. (2 grains) daily; 8, over 0.13 Gm. (2 grains).

Only 5 patients had taken diphenylhydantoin sodium alone. Ten had been unable to take this drug due to toxic effects. Two had never taken diphenylhydantoin sodium but had received phenobarbital alone. All the patients had taken phenobarbital alone or in conjunction with bromides or other barbiturates prior to diphenylhydantoin sodium therapy.

TABLE 1.—*The Age Range of Sixty-Seven Patients with Epilepsy*

Years	Number of Patients	
0 to 10	9	
11 to 20	13	44 patients (ages 11 to 40) 65% of total
21 to 30	20	
31 to 40	11	
41 to 50	6	
51 to 60	6	
61 to 70	2	

Approximately 50 per cent of the patients reported that diphenylhydantoin sodium had reduced the frequency and severity of their grand mal attacks. The other half did not report any significant results. Of all the patients (42 cases) taking up to 0.13 Gm. (2 grains) of phenobarbital with the diphenylhydantoin sodium daily, none reported sufficient drowsiness to cause any interference with daily activities, although the degree of drowsiness varied in individual cases. Many of them agreed that "slight drowsiness was more noticeable in the beginning when I started to take the little white pills, but I do not feel it now. I guess I am used to it." An appreciable tolerance to phenobarbital in almost all patients is apparently established early.

Depending on the severity and frequency of the attacks, 1 to 6 tablets of 3-methyl-5, 5-phenylethylhydantoin and 0.02 to 0.13 Gm. (⅓ to 2 grains) of phenobarbital were taken by each patient daily; the average dose being 4 tablets, 0.4 Gm. (6 grains) of 3-methyl-5,5phenylethylhydantoin and 0.088 Gm. (1⅓ grains) of phenobarbital daily. Kozol's[6] average dose in his initial studies was 0.6 Gm., or 6 tablets, of 3-methyl-5, 5-phenylethylhydantoin daily, but with longer experience he at present considers that the average adult dose is higher. The favorable action of phenobarbital is suggested when it is noted that, in this series, comparative therapeutic results are obtained with an average dose of 4 tablets (0.4 Gm.) of 3-methyl-5,5-phenylethylhydantoin and 0.088 Gm. (1⅓ grains) of phenobarbital daily.

CLINICAL RESULTS

This study is now in its fourth year, which is a reasonable length of time to fairly evaluate therapeutic results. The average expected incidence figure is derived from the number of grand mal attacks each patient experienced during the previous twelve months on the former therapy prior to beginning the new drug. It is to be assumed that this number of major seizures would continue if the new drug had not been given. Of course, it is important to note that many patients experience spontaneous remissions of varying periods, which always complicate any study of therapeutic results in epilepsy. In the majority of cases improvement followed almost immediately, so that the question of spontaneous remissions can hardly play an important role. In addition many of the patients who no longer had any seizures after a reasonable period of

[6] Kozol, H. L.: Epilepsy: Treatment with New Drug, 3-Methyl 5, 5-Phenyl-Ethyl-Hydantoin (Phenantoin), Am. J. Psychiat. **103**: 154 (Sept.) 1946.

time while taking 3-methyl-5, 5-phenylethylhydantoin had the dosage reduced, and in almost all cases a reappearance of grand mal seizures was again reported. Two of these patients had not had any seizures in three years.

The total average expected incidence of grand mal seizures in the 67 patients was 2,891. The actual number of grand mal attacks experienced by these same patients taking 3-methyl-5, 5-phenylethylhydantoin and phenobarbital was 1,140. This represents a reduction in the number of major seizures of approximately 60 per cent. In some cases petit mal and psychomotor seizures were also reduced, but these data were insufficient to be of any statistical value. However, Kozol[7] states that "this drug appears to be highly effective against psychomotor attacks."

In the single case of jacksonian epilepsy of traumatic origin this new anticonvulsant gave dramatic results. The patient, a man aged 45, had been having right lower extremity seizures for seven years. Three outstanding neurosurgeons after thorough and careful examinations agreed that operative measures would be of no avail. The man was taking 8 capsules of diphenylhydantoin sodium, 0.8 Gm. (12 grains) daily and 0.13 Gm. (2 grains) of phenobarbital in divided doses of 0.03 Gm. (½ grain) four times a day. He tolerated this dosage well, and the jacksonian seizures had been reduced from about ten to fifteen daily to about three to five daily. He had voluntarily attempted to increase the dosage of diphenylhydantoin sodium, but it made him nauseated so he continued on 8 capsules daily. Since the seizure of this patient was classified as severe, he was asked to take 0.8 Gm., or 12 grains (8 tablets), of 3-methyl-5, 5-phenylethylhydantoin and 0.17 Gm., or 2⅔ grains, of phenobarbital daily. The seizures ceased promptly. He has had three light jacksonian attacks in one and one-half years since the new regimen was first instituted. In the last three months he has reduced his dosage of the anticonvulsant to only 6 tablets daily without any increase in convulsive movements. This patient's total number of jacksonian seizures has not been included in the expected incidence figure.

Many cases of the predominant grand mal type have resulted in similar dramatic results. In 22 cases, or about one third of the total, the grand mal seizures ceased completely shortly after a regimen of 3-methyl-5, 5-phenylethylhydantoin and phenobarbital was instituted. All these patients, except 1, were in the younger group of 35 years of age or under. The duration of the epilepsy, which varied from one and a half years to twenty years, appeared to play no part in the results of this group. In 7 cases the seizures continued in the same ratio as before the new drug was prescribed. In 6 cases the number of grand mal seizures increased, in spite of adequate dosage and a reasonable trial period. The increase averaged about 10 per cent above the previous incidence. Administration of the drug was discontinued in the latter 6 patients, who were resistant to other types of therapy. In the remaining 32 cases the frequency of grand mal seizures was reduced from 10 per cent to 90 per cent. Of further importance was the fact that the severity of the seizures was definitely lessened. Moreover, most patients experienced fewer postconvulsive ill effects from mild spells than had ensued after the previous severe attacks.

SIDE EFFECTS

Studies of chronic toxicity in animals have shown the drug to be well tolerated (Spiegel[8]). In this study in 4 cases (6 per cent) there developed gingival hypertrophy; in 3 cases (4.5 per cent) skin rash and in 10 cases (15 per cent) slight drowsiness. Hypertrophy of the gums was minimal in all cases, and the drug was continued. In some cases previous gingival hypertrophy caused by diphenylhydantoin sodium actually receded and disappeared with 3-methyl-5, 5-phenylethylhydantoin therapy. This was especially true in the younger group.

In the 3 cases of skin rash, the rash was generalized and of a morbilliform type. In all cases the rash developed within two weeks. The color varied from pink to deep scarlet, was most pronounced on the extremities, especially the flexor surfaces, and was intensely pruritic. In one case, there was desquamation on the fourth day of the rash. Two of the 3 patients had experienced generalized rash previously, but the cause and description could not be obtained, except that the previous rash had also been pruritic. This suggests that the drug should be given with caution to patients who have had previous generalized rash. Phenobarbital and diphenylhydantoin sodium were ruled out as the possible offenders, since all 3 patients had been taking both drugs for long periods without developing any cutaneous rash. Undoubtedly the new anticonvulsant was the causative factor. The dose in each case was within the average normal of 0.3 to 0.4 Gm. (4.5 grains to 6 grains) daily. Kozol[6] has reported a rash incidence of 10 per cent. This occurred in those patients who were given large initial doses. Recently, however, Kozol[7] has reported that treatment has resulted in virtually no rashes, because he starts with small doses and increases the amount of the drug gradually. Evidently the initial amount of drug taken by dermal sensitive patients determines, in direct proportion, the appearance of the rash with all its clinical manifestations. Some patients require a higher dosage to bring latent sensitivity into activity. In all instances the dosage of the drug was promptly discontinued as soon as the patient reported the cutaneous eruption, and in all 3 patients the rash completely disappeared in approximately ten days. In 1 patient there developed, at the onset of the eruption, an elevation of temperature to 103 F., which was maintained for two days. The other 2 patients reported feeling warm. It is obvious that some elevation in temperature accompanies the rash. Blood counts done at the onset and again at the height of the eruption did not reveal any abnormalities except a moderate leukocytosis. Urinalyses were normal. When the rash had completely disappeared, treatment with the drug was reinstituted and the dosage was slowly increased to the previous therapeutic level. Two of the 3 patients were able to take it again without further toxic effects. The drug was again immediately discontinued in the third patient when pruritus was reëxperienced.

Ten patients (15 per cent) complained of drowsiness. In 7 of the 10 cases this side effect was mild.

[8] Spiegel, E.: Unpublished data.

None of these patients was taking more than 4 tablets (0.4 Gm., 6 grains) of 3-methyl-5,5-phenylethylhydantoin and 0.088 Gm., or 1⅓ grains, of phenobarbital daily, and all had taken at least 0.06 Gm. (1 grain) of phenobarbital with the diphenylhydantoin sodium previously without complaining of drowsiness. Kozol[8] stated that "the principal drawback or side effect of 'mesantoin' is that it tends to produce drowsiness." This may be due to the fact that Kozol's[8] average dose of 3-methyl-5,5-phenylethylhydantoin for youths and adults was 0.6 Gm. daily (6 tablets), "with individual variations in the adult dosage ranging from 0.3 Gm. daily to over 1 Gm. daily"; while in this clinic, the average dose for adults is 0.4 Gm. daily (4 tablets), which may explain the low incidence of drowsiness. In all cases the drowsiness was most pronounced in the late morning or early afternoon hours. A few patients requiring larger doses in order to maintain a better anticonvulsant effect did complain of a deeper drowsiness. Some of these patients, in whom it was believed that this undesirable effect was due to phenobarbital, were given the 3-methyl-5,5-phenylethylhydantoin with less phenobarbital, but as the dose of the drug approached the daily level of 0.6 Gm., drowsiness increased. It can be deduced, therefore, that the new anticonvulsant has a soporific effect which is in direct proportion to the size of the dose. Children appear to be more sensitive to this effect than adults. After a period of about four weeks this effect lessens, possibly because of an increased tolerance.

None of the patients complained of any gastric disturbances, such as nausea or vomiting. Few patients complained of nervousness, which is a common manifestation of the epileptic state. This may be due to the fact that almost all the patients were also given small doses of phenobarbital. Ataxia and diplopia, which have been reported after treatment with diphenylhydantoin sodium, were not encountered in this series. Ten patients who were unable to take diphenylhydantoin sodium because of toxic symptoms took 3-methyl-5,5-phenylethylhydantoin and phenobarbital without any toxicity whatsoever, and the results in these patients were as good as in the entire series. The toxicity of the new drug is extremely low, as demonstrated by the excessive amounts (72 tablets) taken at one time in a nonfatal suicidal attempt (Kozol[8]). No effect was noted in the blood picture of most of the patients. In about 40 per cent of the cases the lymphocytes were moderately increased at the expense of the neutrophilic polymorphonuclear cells. This observation is being studied further. Routine urinalyses remained unchanged. Blood pressure readings remained the same as before the drug was instituted. No disturbance of the menses was encountered which might be attributed to this drug.

COMPLICATING ILLNESSES

It would be expected that other illnesses not related to epilepsy would occur in such a group. In 1 patient there developed infectious jaundice, but the jaundice and the other clinical symptoms of this disease cleared up in about three weeks while the patient was on full therapy of 0.4 Gm. (6 grains) of 3-methyl-5,5-phenylethylhydantoin and 0.088 Gm. (1⅓ grains) of phenobarbital daily. In another patient lobar pneumonia developed; 3-methyl-5;5-phenylethylhydantoin (0.3 Gm. daily) and phenobarbital was continued in addition to full doses of sulfadiazine. There were no toxic symptoms, and the pneumonia resolved on the sulfadiazine therapy. One patient suffered a severe skin burn and another fractured an arm in an accident. In both cases satisfactory and normal healing occurred while on full therapy. Four patients became pregnant, and throughout pregnancy full anticonvulsant dosage was continued. No untoward or toxic symptoms were experienced during pregnancy, and all 4 patients underwent normal labors and delivered normal infants.

ROLE OF PHENOBARBITAL

All physicians interested in the therapy of epilepsy are seeking to find a drug which can be given alone and which will be of benefit in a majority of cases. Up to the present this drug has not been found, and a doubt exists if one drug can satisfy all the varied demands of an epileptic attack, which is in reality a symptom complex. The fact remains that the majority of patients on any type of hydantoin therapy require other drugs, usually of the barbiturate group. Many clinicians prescribe barbiturates in addition to the hydantoin because clinical results are in favor of them. The following investigators, in comparative hydantoin studies, have reported better anticonvulsant results when the drug was given in combination with barbiturates: Doltolo and Bennett,[9] Harris and Ewalt,[10] Weaver, Harrell and Arnold,[11] Robinson and Osgood,[12] Cohen, Showstack and Myerson,[13] Merritt and Brenner[14] and Merritt.[15] Beckman[16] in his 1946 edition of "Treatment in General Practice" states: "As a matter of fact most men find that even in the treatment of adults, 'dilantin' (diphenylhydantoin sodium) is best employed in combination with phenobarbital."

Whether the barbiturate effect is synergistic or otherwise can best be determined from the clinical results. As shown by this and other studies, less hydantoin is required by those patients who also combine with it some barbiturate. Less of the drug would, of course, diminish the possibilities of any toxicity that might result from it in hydantoin-sensitive patients. The amount of barbiturate for this effect is usually small. The proper amount must be determined by careful observation in each case. The addition of a small amount of barbiturate usually decreases further the frequency of the grand mal seizures, lessens the severity of the convulsions, allays the anxiety symptoms of the patient and enables the patient to enjoy a more restful sleep. The latter two points greatly help in improving the patient's general well-being, which is just as important as the decrease in the number of seizures.

COMMENT

This study on the effect of 3-methyl-5,5-phenylethylhydantoin on convulsive seizures was begun in June 1943, and the first clinical report of its effect was published in June 1945.[1] Soon thereafter Clein[17] reported the drug to be more effective in epilepsy than any previous medicament and to be almost free of side effects. One year later, in 1946, Kozol[6] reported that "sixty per cent of the patients in the entire series (104 patients) were either greatly or moderately improved on 'mesantoin' therapy." This included grand mal, psychomotor and focal attacks.

This article represents an interim study of 3-methyl-5,5-phenylethylhydantoin, comprising three years of uninterrupted observation by the same clinician. The results of these studies, as well as those of Clein[17] and Kozol[6] demonstrate definitely that this drug is the most effective in reducing the frequency as well as in lessening the severity of epileptic convulsions. It is also the least toxic of all known hydantoins in use at present. This study has shown that a small amount of phenobarbital increases the anticonvulsant action of this drug. This view is also supported by many other clinicians in respect to diphenylhydantoin sodium.

The drug 3-methyl-5,5-phenylethylhydantoin can apparently be used safely during pregnancy without untoward effects. No other drugs, up to the present writing, have been found incompatible with it. Blood chemistry, renal function and blood pressure appear to be unaffected. The effect on the blood, as already discussed, is being studied further. The drug has been given during certain complicating illnesses with good anticonvulsant effect and no toxic symptoms. Further studies should be done in the jacksonian type seizures. Little influence is exerted on other types of epileptic seizures.

CONCLUSION

In a full three years of study with 3-methyl-5,5-phenylethylhydantoin in 67 cooperative patients, the major portion suffering from epilepsy of undetermined cause and a small number from epilepsy of organic origin, grand mal seizures were reduced approximately 60 per cent and improved emotional status was noted consistently. Other types of epileptic seizures, such as petit mal and psychomotor, were not improved with this medicament. Phenobarbital in small doses increased the anticonvulsant action of this drug and in addition controlled the anxiety and other disturbing symptoms from which many epileptic patients suffer. Less drug was required when combined with small amounts of phenobarbital. The toxicity of 3-methyl-5,5-phenylethylhydantoin is extremely low; only 1 patient was unable to take the drug because of a rash. Other toxic symptoms of hydantoins, such as ataxia, nausea, vomiting, dizziness and diplopia, were not encountered in this series.

This interim study as well as the studies of Clein[17] and Kozol[6] support the preliminary observations of 1945[1] that 3-methyl-5,5-phenylethylhydantoin is superior to other hydantoins in present use in the treatment of grand mal seizures.

MEDICAL CONDITIONS IN ALASKA

A Report by a Group Sent by the American Medical Association

HARRY E. BARNETT, M.D.
JACK FIELDS, M.D.
GEORGE MILLES, M.D.
JOSEPH SILVERSTEIN, M.D.
and
ARTHUR BERNSTEIN, M.D.
Chicago

The advisory committee of the American Medical Association to the Department of the Interior appointed a team to study the over-all medical conditions and problems of the territory of Alaska and to render such special advice and aid as could be given.

Alaska was toured for a period of three weeks. The team arrived in Anchorage July 19 and completed its tour on August 9. The following sites were visited: Anchorage, Seward, Bethel, a native village on the Kuskokwim River, Unalakleet, Nome, Gambell on St. Lawrence Island, Kotzebue, Point Barrow, Tanana, Fairbanks, Juneau, Hoonah, Sitka, Ketchikan and Metlakatla. A total of about 4,500 miles was traveled in Alaska.

The team was capably guided by Dr. C. Earl Albrecht and Dr. Leo Gerhig of the Territorial Department of Health and Dr. Howard Rufus of the Alaska Native Service. Physicians of the Alaska Native Service, as well as private practitioners, were consulted as to their problems. Nurses in the field, at Alaska Native Service hospitals and at private hospitals were interviewed. Local officials such as village mayors and councilmen as well as territorial officials were interviewed. A conference was held with Gov. Ernest Gruening.

School facilities were examined and school teachers were interviewed, as they are an important cog in the health of the small isolated communities in Alaska. Statistics on venereal disease were examined, and the military, health officers and private physicians were interviewed. Patients were examined and treatment or suggestions for management were offered. The team performed several operations and examined several hundred patients. The number of places visited and the distances covered gave the team an excellent insight into the situation regarding the over-all medical picture in Alaska.

Alaska is 586,000 square miles in area, or one fifth the size of the United States. It is twice as large as Texas. Distances are greater than many anticipate; the distance from Ketchikan in southeastern Alaska to Attu, westernmost of the Aleutian Islands, is greater than that from New York to San Francisco. From Ketchikan to Point Barrow the distance approximates that from Seattle to the Mexican border. The size of Alaska is readily appreciated by noting the extent of a map of the territory superimposed on a like-scale map of the United States.

The greater part of the northwestern portion of the territory (north of the Alaska Range) has "permafrost," or permanent frost; this is a condition of permanently frozen soil from within a few inches of the surface down to bed rock, several feet to many hundred feet into the earth. This condition hampers the laying of pipes for water supply and sewage disposal, which is such an important feature for proper sanitation and hygiene. The climatic condition of the territory is characterized by low temperatures in the interior (minus 70 F.) and an extremely short growing season in the summer. The territory has not been widely developed from an agricultural standpoint, and food as well as dairy products are imported with resultant high costs of these products.

The present population of Alaska is estimated to be between 90,000 and 100,000; of these 32,000 are natives. The native population has remained unchanged since the purchase of Alaska in 1867. The natives consist of about 15,000 Indians and 15,000 Eskimos and 1,200 Aleuts. The nonnative population has increased since the onset of the war and has continued to increase with the opening of the Alcan Highway and the influx of workers hired by contractors for War and Navy Department activities progressing at this date. The population of Anchorage has grown from 3,400 to 10,000 during the war years, and this trend has continued; hence, an accurate estimate of the population cannot be made. All other cities in Alaska have increased in population, though to a lesser extent; Juneau, Fairbanks, Sitka and other cities have increased about 50 per cent over their prewar census.

Defense of the continental United States, in fact of the whole North American continent, has become a very pertinent factor with regard to Alaska, which has been called the "left flank of the North American Continent." Its strategic position is being emphasized by the recent world unrest. A healthy populace as well as a stable increase of the population of the territory would aid in the defense of Alaska. The territory is also being used for arctic training of the troops, a site which cannot be equaled under the American flag. Again, a healthy populace would reflect on the health of members of the armed forces, as they would then not be exposed to communicable diseases.

TUBERCULOSIS

Tuberculosis constitutes the most urgent and important health problem in Alaska. The statistical data are unassailable, and these with our personal inspection served to impress the committee with the urgency of the problem. In discussions with many private practitioners, physicians of the Alaska Native Service and the territorial health commissioner the problem was emphasized.

Pulmonary tuberculosis was seen at every activity visited. A half day was devoted to the examination of patients in the outpatient clinic at Bethel. Six new cases of open tuberculosis were observed, but the patients had to be sent home because of the lack of facilities for their care. Dr. Langraam, Alaska Native Service physician at Bethel, stated that regardless of the presenting disease 50 per cent of cases were complicated by tuberculosis.

Extrapulmonary tuberculosis was seen to occur in an unusual proportion of the population. These infections consisted of bone and glandular involvement. Cases of tuberculosis of the spine in both the active and inactive stages were a common sight after a short stay in the territory. Many of the extrapulmonary lesions were accompanied by pulmonary involvement, and this complicated the problem of treatment. The majority of the crippled children in the territory had tuberculosis of the bone, as revealed by a recent survey.

The death rate from tuberculosis of 359.1 per hundred thousand for the year 1945-1946 is probably among the highest in the world. The rate for the United States was about 40.1 per hundred thousand. The Alaskan rate is nine times the rate in the states. The native rate is much higher than the over-all rate indicates—perhaps fourteen times the over-all rate in the United States, while the rate for the white population is twice as high as in the states. In the states the over-all death rate from tuberculosis includes the high incidence among the Negro and Mexican segments of the population. It is also common practice among the white population in Alaska to go "outside" for treatment of tuberculosis when the diagnosis is established. (The term "outside" refers to the United States.) The rate, therefore, is not padded by any unusual circumstances but reflects probably a lower trend than is actually true.

The total number of cases of open pulmonary tuberculosis in Alaska approximates 4,500. This figure is arrived at by the usual practice of multiplying the number of deaths from tuberculosis by nine to arrive at a conservative figure of open cases. Incidence in some villages has been established as 25 per cent of the population of the village by recent mass survey statistics.

About 60 per cent of the cases of tuberculosis reported to the health department in 1945 were first reported on the death certificate. This means that in Alaska during 1945 over half of the cases discovered were unrecognized until death. This figure dramatically points to the need of additional efforts at control.

When deaths from tuberculosis are compared to deaths from all causes, including injury, organic disease and suicide, it is found that tuberculosis causes one of every five deaths, or in other words accounts for 20 per cent of the mortality in the territory. The analysis of deaths due to communicable disease in Alaska for 1945 reveals that 69 per cent of all such deaths were due to tuberculosis.

Dr. Rabeau at the Alaska Native Service Hospital in Kotzebue had compiled some decidedly interesting statistics from his records. Kotzebue is a village of 1,200 persons, all Eskimos. For a period of four and one-half years the death rate in this community was 3,600 per hundred thousand. Of these deaths 54.7 per cent were directly the result of tuberculosis, the diagnosis having been proved by autopsy in over half the cases. Dr. Rabeau reported that in a period of seventeen months he cared for 40 patients with tuberculous meningitis. It was his opinion that 25 per cent of all the natives in the community which he served had open tuberculosis, a figure that has been substantiated in several communities by the mass roentgenologic survey now in progress. He further estimated that an additional 35 per cent of the natives had what he would be willing to classify as arrested tuberculosis.

The school teacher at Barrow stated that of 30 children between the ages of 5 and 6 who had entered school but 6 lived to finish. The majority of deaths were due to tuberculosis.

The *M/S Hygiene,* the Territorial Health Boat, reported on a visit in 1945 to Perryville, a village of 70 persons, that there were 7 patients who had far advanced tuberculosis with positive sputums. As a result of this high incidence of active tuberculosis the infant mortality was extremely high. More than one half of the children born in this village died before they were 6 years of age.

The high rate of tuberculosis among the natives can be ascribed to many factors. The natives may have a lower resistance than those of the white race. However, contact is probably the most important factor. In the native villages housing, in the vast majority of instances, is very poor. As many as eleven persons were found living in a single room about 9 by 12 feet, with little ventilation. It is evident that the presence of an open case of tuberculosis would expose all members of the group to large and frequent doses of tubercle bacilli. Furthermore, the native is rather stoical and only infrequently presents himself for medical care in the absence of urgent symptoms, among which he has come to recognize that spitting of blood is especially ominous.

The committee was surprised to learn that up to the spring of 1945 no sanatorium for the treatment of tuberculosis existed in Alaska. Patients, when the case had been diagnosed as tuberculosis, were either sent back home to be cared for by their family or kept in an Alaska Native Service hospital. The latter amounted to custodial care only. The facilities in Alaska up to 1945 totaled a maximum of seventy beds in Alaska Native Service hospitals, and these were for native beneficiaries only. White or nonnative beneficiaries are not cared for by these facilities except in emergencies.

Since 1945 two separate facilities have become available for the treatment of tuberculosis; the sanatorium on Alice Island, Sitka, and the Seward Sanatorium, a total of two hundred and fifty beds. Both of these are reconverted army hospitals of temporary construction. The first is an Alaska Native Service facility, while the latter is a territorial facility leased to the Methodist Mission for management.

The Seward Sanatorium depends on territorial funds, Veteran Administration funds while veterans are hospitalized and Alaska Native Service funds for hospitalized native beneficiaries. The Seward Sanatorium must maintain a hundred and twenty-five bed capacity to be financially sound. While we were in Alaska the Alaska Native Service was forced to withdraw its financial support from the Seward Sanatorium because a deficiency appropriation to cover the native patients in the Seward Sanatorium did not pass in Congress. This last fact struck the committee as a thunderbolt, as it now appears that the Seward Sanatorium has been virtually scuttled.

The existing sanatorium facilities are hopelessly inadequate to stem the tide of tuberculosis. The problem at present is selection of the few patients for admission from the many whose cases have been uncovered, since the number of beds is so limited. Many cases are far advanced and hopeless as to prognosis. The occupancy of a bed by a patient whose case is hopeless seems unfair when perhaps 10 or 12 less seriously ill patients whose disease is more amenable to treatment are awaiting admission. Of course, the hospitalized patient in the hopeless case is at least removed from his family and the public and so does not serve as a disseminator of the disease.

In each Alaska Native Service hospital a few beds are provided for the care of tuberculosis. These are general hospitals, and where a physician is in residence, as at Kotzebue, Bethel and Juneau, tuberculosis patients were in good proportion to the total number of beds. In hospitals that did not have a resident physician the bed capacity was not utilized and tuberculosis patients were not in adequate proportion to the occupied beds. The latter was true in such places as Barrow and Tanana. In the general hospitals of the Alaska Native Service treatment of tuberculosis amounts to custodial care for the most part, and only at Bethel and Juneau were pneumothoraces performed.

The case finding program of the Territorial Department of Health is progressing very satisfactorily. Three separate equipments are being utilized. First, the *M/S Hygiene,* the Territorial Health Boat, travels Alaska's shoreline calling at isolated villages from Ketchikan and Metlakatla to Nome. This work is continuing and will be a year round project of the Department of Health. Second, a 4 by 5 General Electric 200 milliampere photofluorographic unit is being transported from one large city to another in the territory. This unit was operating in Anchorage when the committee first arrived in Alaska. This unit will continue its circuit throughout the larger cities of the territory, including Palmer, Fairbanks, Nome, Unalakleet and possibly Bethel, Seward, Kodiak, Juneau and Sitka. When this itinerary is completed the residents of all cities of a population greater than 1,500 to 2,000 will have been examined. Third, the Mobile Health Unit, an army small arms repair truck, is equipped with clinic facilities, health education materials and a 30 milliampere portable Picker X-Ray machine. This mobile unit serves the highway system of the territory.

The last method of roentgen examination of territorial residents is through the private physicians and hospitals. The Territorial Department of Health pays $2.50 and furnishes the film for any roentgenogram taken on persons suspected of having tuberculosis. This program resulted in approximately 3,000 roentgenograms during the past year, all of which were interpreted at the Juneau office.

Further plans for case finding include the use of a 30 milliampere portable Picker Field Unit, which can be transported by plane in smaller communities. These communities cannot be reached by road, rail or boat. It is in these smaller villages that the incidence of tuberculosis is high.

The after-care and rehabilitation of tuberculosis patients is almost a nonexistent project in Alaska. Territorial funds were appropriated during the special session of the Territorial Legislature in 1945 for such a program to be operated under the Social Security Agency. A subsequent appropriation for this program at the 1946 legislative session was totally inadequate to carry out the intent of this program. At present the only effort at rehabilitation possible will be made with the aid of the limited funds available from the Alaska Tuberculosis Association. These will consist in a wholly inadequate program of occupational therapy and organized amusement of patients in the sanatoriums.

A central case registry for tuberculosis has been started in the Juneau office of the Territorial Department of Health. It has been indicated that the registry will be divided, in that all cases from the interior of Alaska will be filed in Anchorage. This will facilitate the management of the control problem in the interior.

The committee saw a number of patients with open cases housed in 9 by 12 foot rooms among eight to twelve persons, all members of one family. Can isolation be practiced in such homes? Is it a wonder that the life expectancy of the natives is so short? The Barrow school teacher's statement tells the story; he said: "Of a class of 30 that entered school, 6 have lived to graduate." Is it a wonder that the total native population of Alaska has not increased from what it was when the territory was purchased in 1867?

Tuberculosis is a preventable disease. The white plague can be controlled in Alaska and in a period of five to eight years the death rate and incidence need not be greater than in the best areas in the United States.

For those who decry federal aid the committee wishes to point out that the problem in Alaska has existed for many, many years without even an effort toward a solution until 1945. The territorial funds are insufficient to meet the present needs of Alaska in tuberculosis control. Alaska has been a neglected possession of the United States up to recent years. The war years and its present eminence as the "left flank of the North American Continent" have brought Alaska into the national conscience. The citizens of Alaska, its officials and the health authorities are cognizant of the acute problems. Defense of Alaska would best be accomplished with a healthy populace.

In the face of the serious tuberculosis problem in Alaska, Congress has seen fit to reduce the already meager funds of the Alaska Native Service for the care of the tuberculous. It must be emphasized to those who may be color or race conscious that the tubercle bacillus knows no color line. To those who measure in terms of tax dollars it must be evident that in a course of years inadequate attempts at control of tuberculosis is wasteful. To the industrialist and employer who think in terms of production, it must be pointed out that a labor market grossly infected with tuberculosis is an economic liability. To the military who are prone to think in terms of effective fire power the ever present danger of tuberculosis is both a direct impediment to the efficiency of their forces and a demoralizing factor. Finally, to the parents, relatives and friends of those going to Alaska, both as civilians and in armed forces, the rate of tuberculosis in the territory constitutes an ever present danger.

EYE HEALTH SURVEY

The Eye Survey was carried on at all localities visited. About 50 to 60 natives were examined in each village. The total number examined was well over 600. The persons were taken at random, and the majority were children. The greater part of the study was among the Eskimos.

Early in the course of the tour it became evident that corneal opacities among the Eskimo natives were extremely prevalent. These lesions were a result of acute processes in the early years of their life, and later the resultant scars caused poor vision. The universal distribution of corneal lesions among the villages of arctic Alaska was striking.

The ocular pathologic processes noted in order of frequency were phlyctenular keratitis (inactive), phlyctenular pannus (active), phlyctenular keratitis (active), phlyctenular conjunctivitis (active), chronic conjunctivitis (cause undetermined), angular conjunctivitis (cause undetermined), squamous blepharitis and phthisis bulbi. Many cases of convergent strabismus were seen. In the older age group senile cataracts in the various stages of progression were noted, some of them in need of extraction.

The observations revealed that from 22 to 50 per cent of the children examined in any village exhibited corneal opacities. Some villages had a higher incidence than others. These opacities varied from pinhead-sized infiltrates, nebulous in character and not interfering with vision, to large dense leukomatous opacities causing a decided reduction in vision. All parts of the cornea seemed to be involved. The consequences of these corneal lesions are reflected in the following observation: of the 600 persons examined, 40 had corrected visual acuity of 20/100 or less. This figure is referred to as "industrial blindness."

Coincident with this committee's tour, an ophthalmologist employed by the Territorial Department of Health under the auspices of the Vision Conservation Program was just completing a six weeks' study. In comparing the statistics of the various ocular diseases it was found that the observations were similar. Independently the opinions agreed as to the probable causes and management of these conditions.

It is considered that there is no association between the corneal lesions and trauma, malnutrition, tuberculosis, exposure or actinic rays. The causes of the corneal opacities were not determined in this survey. The opportunities for etiologic studies could not be used to advantage in a short visit. The contributing factors of these corneal involvements can be listed as follows: (1) poor personal hygiene, which permits the growth of the staphylococcus or other organisms; (2) totally inadequate medical facilities for diagnosis and treatment in children between birth and 5 years of age, when these corneal lesions occur, and (3) the lack of knowledge on the part of the physicians, nurses, school teachers and parents as to the connection between the "sore eyes" of infancy and the corneal opacities of later childhood and adult life. An interesting observation was made at Gambell, St. Lawrence Island. Here 50 children were examined and only 2 instances of corneal opacities were noted. It proved that these 2 children had been adopted from Nome and had come to Gambell recently. It is in Gambell that the school includes showers every Friday as part of the school curriculum.

Alaska does not have a qualified ophthalmologist. Numerous cases require surgery. Many patients with corneal opacities would be benefited by corneal transplants. Refractions for the presbyopic persons to aid them in carrying on their occupations are not available in small communities.

The ophthalmologist of this team performed the following surgical procedures: strabismus cases, 2; enucleation, 1, and cataract extraction, 1.

VENEREAL DISEASE

Venereal disease is one of the serious medical problems of the Territory of Alaska. The problem is especially serious in the larger cities, where recent increments of population have occurred due to defense work. The areas are usually in close proximity to military posts, and the incidence of venereal disease among the military personnel is unusually high. This latter is true in such places as Fairbanks and Anchorage.

The biennial report of the Office of the Commissioner of Health for the period July 1, 1944 to June 30, 1946 revealed a decrease in the incidence of syphilis but an increase in the incidence of gonorrhea during the fiscal year 1945-1946 as contrasted with the year 1944-1945. This report included venereal diseases occurring in military personnel. Since many troops left the territory during the latter part of the reported period, it is evident that the increase of gonorrhea is definitely significant.

Many factors contribute to the present incidence of venereal disease. Among these may be included alcoholism, the "line," the preponderance of male over female inhabitants and the rapid expansion of population due to defense activities.

Alcoholism plays an important role in spreading venereal disease. General Everest, the commanding officer of Ladd Field, informed this group that most of the soldiers infected stated that they had been intoxicated at the time of exposure.

In Fairbanks the community condones open prostitution. "The line" extends along Fourth Street, in the very heart of town. Twenty-three inmates of this street openly solicit and are unmolested. Control of venereal disease cannot be accomplished under these circumstances. Community indifference and outmoded ideas of "family protection" are the most important reasons for the existence of the professional prostitutes. Financial gains to the property owners may be another reason.

The Territorial Department of Health has been making a concerted effort to combat venereal disease. It has distributed literature to the physicians explaining in detail the accepted modern modes of treatment of venereal disease, and it has furnished without charge *diagnostic and therapeutic measures for control* of venereal diseases.

Several physicians in private practice who were interviewed said that they were prevented from completing a course of antivenereal treatment in indigent patients because of lack of medicaments. The commissioner of health, Dr. C. Earl Albrecht, explained that there were no funds available for further purchases of drugs.

The Territorial Department of Health received $24,200 of venereal disease funds for the fiscal year of 1948. A considerable amount of this must be applied to the support of four laboratories: Ketchikan, Juneau, Anchorage and the *M/S Hygiene*. A relatively small amount goes toward administrative and nursing budgets and the remainder to direct venereal disease control measures. It is wholly inadequate to curb the spread of gonorrhea and syphilis. Fortunately, however, a grant of $7,000 from the U. S. Public Health Service for the rapid treatment of syphilis was received recently. This will help, but additional funds or their equivalent in personnel or drugs for other venereal control measures is needed.

The reason Alaska gets only $24,200 is the injustice of the allotment system. Ninety thousand persons are spread out and are overburdened with literally tens of thousands of troops and construction workers for rehabilitation, defense and civilian construction. Alaska has the need for intensive venereal disease control assistance by the U. S. Public Health Service. The tragedy is the spread of venereal disease to isolated native groups who were clean in the past and now have been infected and have taken it back to their homes and communities. It is simply getting out of control.

At present the venereal disease program is administered by the territorial commissioner of health under the Division of Communicable and Preventable Disease Control. This is a weak link in the chain of control. The commissioner of health has so many duties, the most important being administration and organization of his department, that the Division of Communicable and Preventable Disease Control suffers as a result. A separate person should be in charge of the Division of Communicable and Preventable Disease Control. The function of this division is an exceedingly important one, not only as regards venereal disease control. The U. S. Public Health Service should supply the director as well as sufficient financial aid to assist Alaska in its fight against venereal and other communicable diseases. The problems exist because of recent increases in the population, mostly transients, and as a result of defense activities in the territory. The problem of venereal diseases among the military makes it one for federal subsidy.

COMMUNICABLE DISEASES

Communicable diseases, other than tuberculosis, are an ever present threat in Alaska. The danger is aggravated by the recent increase in population due to defense work, Alaskan Railroad rehabilitation program, dependents of the armed forces and transients. The general substandard sanitation and housing facilities that exist throughout the territory make the problem an urgent and potentially dangerous one. It is surprising that serious outbreaks of diseases have not occurred.

The committee was informed of a current outbreak of typhoid in two separate areas of the territory during our visit, July 1947. Four proved cases occurred in the village of Nenana and 3 cases at Anchorage. Nenana has no hospital facilities, while at Anchorage the hospital facilities are inadequate for the community and there are no isolation beds.

The committee was impressed with the fact that none of the existing hospital facilities provide beds for the isolation of communicable diseases. During an epidemic of diphtheria in Anchorage in August 1946, 35 patients were isolated in a quonset hut.

Alaska has many ports through which diseases may be carried into the territory. The rat population of many of these ports is in such proportion as to make plague a real threat.

All the exanthems as well as influenza and enteric diseases have been reported in the territory each year. Measles, diphtheria and influenza have occurred in epidemic proportions. Tularemia and trichinosis have occurred, though not in serious numbers. An epizootic of rabies has occurred along the Yukon and Kuskokwim River areas, and its greatest severity was manifest along the upper region of this drainage. No human cases of rabies were reported, but several persons were given the Pasteur treatment as a precautionary measure when they reported that they had been attacked by animals displaying symptoms of "madness."

International travel through Alaska is expanding rapidly. Regulations, appropriations and personnel should be provided for this.

SANITATION

Sanitation and engineering is a division of the Territorial Department of Health. The sanitation and engineering program is comprised of education, inspection, consultation and enforcement services to the public and to persons on the subject of sanitation in the following fields:

1. Water supply
2. Sewage disposal
3. Food handling
4. Milk supply
5. Salmon, clam, crab and shrimp processing
6. Practice of cosmetology and barbering
7. Operation of hotels and rooming houses
8. Garbage collection and disposal
9. Housing
10. Swimming pool and bathing beach construction and operation
11. Interstate carrier watering points
12. Bottled waters and beverages
13. Water pollution
14. Plumbing
15. Heating, lighting and ventilation of dormitories, schools and public buildings
16. Rodent control
17. Industrial hygiene
18. Property and public health nuisances; requests for advice from private individuals, and requests for advice from local health officials.

The application of principles of basic sanitation was among the first organized public health endeavor in Alaska and started about eleven years ago. In spite of progress, much still remains to be done if the environmental sanitation of Alaskan communities is to meet reasonable standards.

Personnel problems in the Division of Sanitation and Engineering have been very trying in the past few years. Unsettled war and postwar conditions, combined with the high cost of living in Alaska and housing problems, were doubtlessly the cause for a great turnover. During the greater part of the biennium of July 1, 1944 to June 30, 1946 there were two or three professional employees and two clerical employees. This situation has not improved since these dates. Seven different professional employees and seven different clerical employees were on duty with the division during the biennium July 1, 1944 to June 30, 1946. The services of four of the seven professional employees who were on duty with the division were loaned to the Department of Health by the U. S. Public Health Service during the above reported biennium. The division staff has been limited to two or three professional employees during practically all of its existence, and few of the personnel have remained over a year or two.

The facts regarding personnel emphasize the inadequacy of the solution of the sanitation problems, especially in view of the extensive list of duties of the Division of Sanitation and Engineering, as previously mentioned.

The difficulties that confront work in sanitation and engineering in Alaska are those of geography and climate. The great distances between inhabited points and the difficulty in reaching these places become self evident when the map is consulted. Climate, especially in the arctic, is an ever present hazard and problem. Permafrost exists in the entire arctic region; in winter the earth is solidly frozen up to the surface with concomitant external temperatures of minus 70 F. One can easily visualize the difficulties in laying water and sewer pipes.

The committee saw at first hand the problem that exists in Nome. Water is piped into the homes and business places during the summer, for a period of three months. At all other times it is purchased in gallon quantities from carts and water wagons. The sewage condition is much worse. No flush toilets exist in Nome except on the street facing the ocean beach. The toilet facilities consist of simply a bucket, and a crew of pick-up men making the rounds at intervals. The latter is referred to as "the honey wagon." The situation would be humorous, with the stories of frozen buckets in winter, if it were not so serious. The city of Nome, either because of finances or inertia of its citizens, has not been able to solve its sanitation problem.

Public sewerage and sewage disposal methods were inspected in most of the principal towns and in many small villages and outlying areas. These inspections disclosed the continued improper discharge of community sewage on tidal flats, in small streams and on beaches in most of the coastal towns.

In the biennial report for the period July 1, 1944 to June 30, 1946 a careful study of known conditions of three significant features of sanitation—public water supply, public sewage and garbage disposal—are reviewed. Existing conditions were compared, community by community, on a percentage-of-adequacy basis, with recognized standards of good United States practice. While it was evident that much improvement in basic sanitation is needed, many communities, such as the villages of arctic Alaska, cannot economically provide all the protection and conveniences of year around, citywide water and sewer systems.

Average Per Cent Adequacy of Sanitation Facilities

Judicial Division	Water Supply, %	Sewerage, %	Garbage Disposal, %
I Southeastern	59.0	38.0	29.0
II Arctic and Bering Coastal	2.5	0.5	3.0
III Southern Pacific Coastal	22.0	18.0	17.0
IV Interior	7.5	11.0	10.0
Entire territory	30.0	20.0	17.0

The data in the accompanying table show clearly the great need for major improvements in public water supply and sewerage systems.

The committee was impressed with the vast duties of the Division of Sanitation and Engineering, and discussions with the health authorities emphasized this. As an example it may be cited that there are four hundred canneries in Alaska. It is difficult to conceive that all of these are properly inspected during the short season in which they operate.

PERSONNEL

The problem of attracting well trained persons into the territory to fill the needs of all specialized fields is an extremely important one at this time. The Territorial Department of Health and other agencies dealing with health, such as the Alaska Native Service, have difficulty in filling positions. The efficiency of government throughout the territory is being seriously impaired by the lack of personnel. The annual turnover among federal agencies in the Anchorage area varies from a low of 35 per cent in the Civil Aeronautics Administration to 120 per cent in the War Assets Administration. The average term of employment in the Territorial Department of Health is nine months. The weather bureau, the Alaska Railroad, the school system and most other agencies face the same problem.

Personnel problems in the Division of Sanitation and Engineering have been very trying in the past few years, as has previously been stated. The Territorial Department of Health, as well as the Alaska Native Service, has unfilled positions for physicians. The resultant lack of medical care reflects on the over-all health condition of the territory. The reasons for the personnel problems can be attributed to the following factors: high cost of living in the territory; isolation of the individual in remote communities away from professional contacts, and, finally, the housing shortage.

The high cost of living is attributed to the fact that most of the food and all other commodities are imported from the states. Freight and shipping rates added to the cost of a moderately priced item of food, clothing, utensil or furniture results in a sizable increase over the price in the states.

The wage differential for employees of the territory is not remarkable. Salaries for employees of the Territorial Department of Health are similar to those in the states for comparable positions. Salaries of employees of the U. S. Public Health Service assigned for duty with the Department of Health have a 10 per cent differential for "overseas" pay. Civil service employees of the Department of the Interior, of which the Alaska Native Service is a division, have a 25 per cent differential in salary for service in Alaska.

Unskilled workers as well as those skilled in trades in Alaska receive unusually high salaries on the open labor market. The territory is at a decided disadvantage in competing with this market. The committee was informed that two employees of the Division of Sanitation and Engineering had resigned recently to accept positions as policemen in Fairbanks.

Isolation, especially of a physician, in remote villages in Alaska for an indefinite period is a deterrent in attracting capable men. Professional contacts do not exist. Facilities for postgraduate training have not been provided. In order to obtain postgraduate training a physician would have to return to the states and extend his leave of absence at his own expense.

Housing shortages without any doubt are the chief deterrent to the encouragement of permanent residence in the territory at the present time. Families have come to the territory with a good job and adequate finances but after weeks or months in a hotel room have given up in despair and returned to the states. Efforts of such governmental agencies as the Alaska Railroad, War Department and Civil Aeronautics Authority to provide housing for their employees are commendable. However, the health agencies have not been as active in providing abodes for their employees. Alaska Native Service hospital facilities at Tanana and Kotzebue are without housing for a physician and his family.

HOSPITALS

The following hospitals were inspected by the Committee:

Anchorage

The Provident Hospital is a modern fifty-five bed fire-resistant building with extremely modern equipment. It is well staffed and well furnished. It is by far the best hospital physical plant visited. It is run by a Catholic order of Sisters.

Seward

The Seward General Hospital is a small one and one-half story wooden structure, a single room being used on the second floor. It is old and appears to be in a rather poor state of repair and is overcrowded. It is distinctly a fire hazard. The Methodist Board operates this hospital.

The Seward Sanitarium is an army hospital taken over by the Territorial Health Department and leased to the Methodist Board. It is a temporary army hospital of unit type, one story, wood construction and with adequate fire breaks and fire protection. It appears to be well equipped and in a good state of repair. This type of construction is expensive to maintain.

Bethel

This Alaskan Native Service hospital is a two story, thirty-six bed wooden structure in excellent physical repair. There is considerable overcrowding as indicated by the fact that a few pediatric patients were in wheelchairs. The equipment is good.

Nome

The Maynard Columbus Hospital, operated by the Methodist Board, is a two story wooden structure. The building is old, in a poor state of repair, and has a decided list due to the settling of the foundation. The main stairway to the second floor is narrow. The building is a fire trap. It should be replaced before a serious catastrophe occurs.

Kotzebue

This Alaska Native Service hospital is an old, two story, thirty-one bed wooden structure in a good state of repair. It was overcrowded.

Barrow

This Alaska Native Service hospital is a two story, eighteen bed wooden structure, comparatively new, well equipped and designed.

Tanana

This Alaska Native Service hospital is a two story, thirty-three bed wooden structure, comparatively new, well equipped and designed. No facilities for living quarters for a physician are provided.

Fairbanks

The St. Joseph Hospital is a three story, asbestos-shingled, wooden-framed building, comparatively modern and relatively well equipped. It is conducted by a Catholic order of Sisters. It appears to be rather crowded.

Juneau

The Alaska Native Service operates a two story frame hospital. It is a general hospital with a few beds for tuberculosis. Because of lack of funds it is being reduced to fifteen beds.

The general hospital is frame and concrete. It appears to be in a good state of repair. It was not given a detailed inspection.

Sitka

There is no public hospital in Sitka. The local population depends on the beds in the Pioneers' Home. This facility is made available with some reluctance on the part of the authorities, and while this building is of excellent and fireproof construction and the hospital section is well equipped, it does not appear to meet the needs of a community of this size. Obstetric cases are delivered in the Salvation Army Home.

Alice Island—Sitka

The tuberculosis sanatorium is a temporary army hospital of single story units, wooden construction, and adequately protected from the hazard of fire. It appears to be rather well equipped.

The Orthopaedic Hospital and Mt. Edgecombe Infirmary: These two units are housed in a permanent, semifireproof, two story building constructed by the Navy. The physical plant and equipment are superior.

Ketchikan

The general hospital is operated by a Catholic order of Sisters. It is a three story frame and concrete building in a good state of repair. It is something of a fire hazard.

The general hospitals of the territory are grossly inadequate to meet the medical needs of Alaska. In all but one of the sites visited (i. e., Ketchikan) the hospitals were inadequate from the point of view of bed-capacity and in most places the physical plant was also inadequate. The insufficient hospital facilities can be attributed to the rapid growth of the population in the larger cities of Alaska as well as the fact that civilian hospital construction has lagged during the past several years. The causes for the latter are the same as for the shortage of housing in general, namely, scarcity of materials and high building costs.

Most of the hospitals surveyed were wooden, and the committee was impressed with the fire hazard that these buildings presented. Indeed, it was reported that two hospitals had burned in the past year. These hospitals were at Palmer and Valdez, and the communities are now without any hospital facilities. The hospital at Nome (Maynard Columbus) gave the impression of "a tragedy waiting to happen."

The general cost of hospital construction in Alaska is appreciably greater than in the states and is probably more than 50 per cent higher per bed. The per bed cost of construction decreases up to a certain point with hospitals of increasing bed capacity. A fifty bed hospital is more expensive to construct per bed than a two hundred bed institution. This is because certain of the utilities, such as heating plant and laundry, are inherently the same for a small as for a large hospital.

The Hospital Survey and Construction Act has provided funds to states or territories in which a comprehensive study has resulted in the formulation of an acceptable and coordinated hospital plan. Alaska has complied with this requirement. The Hospital Survey and Planning Unit of the Territorial Department of Health is under the administrative direction of the Board of Health.

The allotment to Alaska from the federal government's $3,000,000 fund for survey and planning is $10,000. This is to be matched by territorial funds in the ratio of $2 of territorial funds for each $1 of federal funds. The payment of the $10,000 allotment to Alaska has been made, and the survey is in progress.

The federal fund for hospital construction is $75,000,000, of which $41,400 is available to Alaska. The matching ratio of territorial and federal funds remains 2:1. The federal allotment is based on population and other factors. It penalizes the more thinly populated states and territories, because their need is relatively greater than their ability to match funds.

MENTAL HOSPITAL

No hospital for the care and study of mental diseases exists in Alaska. Indeed, there is no facility of any type available for mental patients. All persons committed to an institution for reason of mental disease are sent to Morningside, Ore.

The procedure of committing a person to a mental hospital is archaic and bears reporting. Any person may swear out a warrant attesting to the mental ills or incapacity of another. The "suspect" is then placed in confinement in a federal jail for ten days. During this time two physicians must examine the "suspect" and make statements as to their findings in the case. A jury then weighs the facts and signs the commitment papers if the patient is adjudged insane. The marshal then transports the patient to Morningside, Ore.

It should be observed that any citizen may make another a "suspect" only by swearing out a warrant; that the patient is confined in jail; that psychiatric studies are not mandatory and indeed are not possible, as only one physician in the territory practices psychiatry, and that only the marshal has custody of and transports the patient a considerable distance to Morningside, Ore. The marshal usually waits until he has an appreciable number of patients before he makes the trip "outside." Three hundred and ninety patients from the territory are at present confined in the sanatorium in Oregon. The Department of the Interior bears the expense of these confinements on a per diem per patient basis.

ALCOHOLISM

Alcoholism has assumed the proportions of an important problem in Alaska. In discussing the general and over-all health problems of the territory with physicians, teachers, military authorities and the "man on the street," the subject of alcoholism was always spontaneously referred to by them.

Alcoholism can rightly be classified as a disease. It accounts for a great deal of human suffering to both the victim and his dependents. Indigency, venereal diseases, poor housing, poor nutrition and general poor health can be attributed directly or indirectly to alcohol.

Alaska has been cited to the committee as having a larger per capita rate of alcohol consumption than any state.

The native does not appear to tolerate alcohol as well as the white man. In villages where alcohol was not permitted it was observed that housing and the general conditions were very good. The natives of these villages were well clothed and were better nourished. In villages where alcohol was sold the situation was quite reversed. It became easy, after a while, to determine from casual observation of the village whether alcohol was or was not a problem.

HOUSING

The acute housing shortage in Alaska enters into every phase of a discussion about the territory. Personnel problems in every governmental department as well as in private industry are related to the lack of adequate housing. The whole economy and defense of Alaska hinges on a stable permanent populace, and this is hindered by the housing problem.

Housing has not kept pace with the increase in population. During the war there was a complete restriction on the transportation of building materials for private use. Since the end of the war such factors as freight rates and scarcity of materials and skilled workers have combined to prevent the fulfilment of the need for more housing.

Not only is the quantity of housing appallingly insufficient, but the quality throughout the territory is extremely bad. It can be stated conservatively that 50 per cent of the housing in Alaska is substandard. Hundreds of houses in the coastal towns are built on piling over tidewater, and many have large and ancient accumulations of garbage and sewage beneath them. Hundreds of families, particularly in the vicinities of Anchorage and Fairbanks and along the highway, are living in huts, cabins, hovels, tarpaper shacks, tents and trailers. These dwellings are not situated where standardized and supervised facilities for water supply, sewage and garbage disposal exist.

It should be particularly emphasized that the entire situation not only is deleterious to the health of Alaska at present but is fraught with potential dangers for the future.

SUMMARY

The observations of this committee were essentially in agreement with the opinions previously expressed by the health authorities and other interested persons in the Territory of Alaska. The committee's tour of three weeks was a fairly comprehensive one, as the territory was traversed for a distance of 4,500 miles and all important parts, with the exception of the Aleutian chain, were visited. All facilities were made available to the committee, and these, with personal inspections, examination of patients and interviews, rounded out the perspective.

It must be evident immediately that the medical problems of a community the size of the Territory of Alaska are numerous and diverse. The climatic conditions and the lack of adequate transportation facilities serve to accentuate these problems.

Tuberculosis.—This is the most serious and urgent problem which faces the territory at present. The death rate is nine times greater than that of the United States. Facilities for the isolation, medical treatment and rehabilitation of tubercular patients are grossly inadequate. The recent removal of government financial support from one of the two available sanatoriums has seriously hampered the existing hospital situation. Alaska is an important cog in the defense of the United States only if its inhabitants are healthy. This is a problem which concerns the federal government and, as such, sufficient federal funds must be made available for its solution.

Eye Health.—Ulcers of the cornea and the resulting opacities with poor vision are widespread among the natives. The causes have not been determined and bear investigation. No ophthalmologist resides in the territory.

Venereal Disease Control.—The problem of venereal disease is becoming increasingly serious. Organized prostitution and alcoholism together with the rapid increase of population, both military and civilian, have been contributing factors. There are insufficient funds available for adequate treatment, especially among the indigent, and for an urgently needed venereal disease educational program.

Communicable Diseases.—The situation with regard to communicable diseases here is potentially very dangerous. Poor sanitation, inadequate housing and a rapidly expanding population are factors which breed epidemics of an explosive nature. No facilities exist for the isolation of patients with communicable diseases.

Sanitation.—Sanitation is very poor throughout Alaska, but especially so in the arctic regions where permafrost creates additional problems. Local communities have been unable adequately to establish a satisfactory water supply or sewage disposal system. The Territorial Division of Sanitation and Engineering is handicapped by serious personnel problems.

Orthopedics.—The principal cause of deformity and disability of the musculoskeletal system in persons in Alaska is tuberculosis of the bones and joints. The acquisition of Dr. Phillip H. Moore to head the orthopedic hospital at Sitka has been a great step forward in the care of these cases. A second orthopedic center at Anchorage to provide for 75 patients would probably be able to care for all additional orthopedic cases requiring hospital treatment.

Personnel.—Three main factors have deterred persons from accepting and holding positions in the territory. These are the high cost of living, the housing shortage and the isolation in remote communities.

Hospitals.—General hospitals are grossly inadequate to meet the current medical needs of Alaska, and if a sudden emergency were to arise the situation would be catastrophic. Again this is the result of a rapidly increasing population and a wartime lag in construction. Two hospitals have been recently destroyed by fire and many of the others are potential fire traps. There are no mental hospitals anywhere in Alaska.

Alcoholism.—The disease of alcoholism is of sufficient importance in Alaska to be mentioned as a factor contributing to many of the unsatisfactory conditions mentioned in this report.

Housing.—There is an acute shortage of satisfactory living quarters throughout the territory. This shortage seriously affects the health and the general economy of Alaska. The solution of the problem should be aided by active federal participation.

RECOMMENDATIONS

1. *Hospitals.*—There is danger of fire ever present in the presence of wooden hospital buildings. Furthermore, maintenance of wooden buildings is expensive. In spite of their high initial cost, it is urgent that new hospital construction be of a simple, fire-resistant type.

A. Beds for Tuberculous Patients: A minimum of one thousand beds should be provided at once for patients suffering from tuberculosis. This number includes sanatorium beds for the active treatment of tuberculosis as well as isolation units added to present scattered facilities. The isolation units will provide custodial care locally for patients with terminal disease and serve as diagnostic stations. The suggested localities and recommended number of beds are as follows:

Southeastern Alaska: Two hundred and twenty sanatorium beds by expansion of the present facilities at Alice Island.

Anchorage area: Four hundred sanatorium beds. This site is the center of population of Alaska as well as the most easily accessible one by virtue of the Alaska Railroad and highway.

Arctic area: One hundred bed sanatorium in Fairbanks.

Isolation units: Twenty-five beds each in Bethel, Kotzebue, Unalakleet, Fort Yukon and Nome. Government surplus quonset huts or other buildings may be obtained, and the units can be operated as an addition to the present Alaska Native Service or other hospitals.

B. General Hospital Beds:

Replace the hospital facilities at Palmer and Valdez, which have been destroyed by fire.

Build a hospital at Sitka, where the present facilities are makeshift and inadequate.

Replace the hospitals at Nome and Seward before a major catastrophe occurs.

Increase facilities at Fairbanks, Anchorage, Ketchikan and Juneau.

The foregoing recommendations for general hospital beds are made in keeping with the present needs as well as the growing population. The committee is cognizant of the fact that a hospital survey is under way by the Territorial Department of Health as provided by the Federal Hospital Survey and Construction Act. Specific facts and recommendations will result from this survey.

C. Communicable Disease Isolation Facilities: There are no beds for communicable disease. It is recommended that such facilities be incorporated in all general hospitals on the basis of population needs.

D. Orthopedic Beds: Fifty to seventy-five orthopedic beds are needed in the Anchorage area.

E. Mental Hospital: There should be a centrally located mental hospital. One such hospital can provide for the needs of the territory.

F. Anchorage Area: It is recommended that federal agencies and the local community in Anchorage jointly plan their hospital needs in order to eliminate duplication. The committee was informed that there are some forty federal agency offices in Anchorage.[1] The Alaska Railroad has estimated that it requires one hundred hospital beds. Other agencies have a need for and are planning for hospital facilities.

In planning for chronic diseases such as tuberculosis, orthopedics, mental diseases and other chronic conditions, the needs of other than federal beneficiaries must be kept in mind.

A hospital of seven hundred beds, broken down into four hundred for tuberculosis, seventy-five for orthopedics, one hundred for Alaska Native Service general, one hundred for Alaska Railroad general and twenty-five for communicable diseases, is recommended.

2. *Medical Needs for Alaska Native Service.*—A. Hospitals: Present bed capacity of the Alaska Native Service hospitals in the isolated areas is adequate if chronic diseases such as tuberculosis and orthopedics are removed to centers for special care, though each should have facilities for the isolation of communicable diseases including tuberculosis.

All Alaska Native Service hospitals need adequate equipment and maintenance. Critical equipment such as x-ray machines, oxygen units, sterilizers and motor vehicles (ambulances preferred) are needed at all hospitals. The hospital at Kotzebue especially requires a sterilizer and x-ray equipment.

If personnel is to be attracted, living quarters for a physician and his family must be provided at Kotzebue, Tanana and other installations which lack them.

The hospital at Kotzebue should be replaced after more urgent needs have been met.

B. Personnel: There are no physicians at present at Barrow, Tanana and Kanakanak, though appropriations for these positions have been made.

Positions for nurses, dentists and physicians are unfilled, with resultant serious effects on the over-all health problems.

Cognizance should be taken of the extreme isolation of many of the Alaska Native Service facilities. In order to attract desirable medical personnel an attractive employment contract should be set up. It should contain provisions for returning the physician to medical centers, at the expense of the Service, for postgraduate training at intervals of not more than three years.

Recognition of the fact that there is such extreme isolation should result in careful selection of physicians as regards individual adaptability.

Nursing personnel should have a choice of rotation in the different facilities as well as postgraduate training. Their work in isolated hospitals entails more x-ray and laboratory duties than are ordinarily expected of nurses. They should be trained in roentgenologic technic, in the performance of simple laboratory procedures and in anesthesia.

Nonprofessional personnel: Nonprofessional personnel must, of necessity, be drawn from the native population and must be trained in local medical installations. Physicians and nurses should be indoctrinated in this point of view.

3. *Tuberculosis.*—The disease of tuberculosis is prevalent in the native population. It is important to federal interests that the federal government provide a large share of the funds for its control.

A. Case Finding:

The approved methods and present efforts of the Territorial Department of Health toward mass roentgenologic case finding should be enhanced by more federal funds for reasons of the immensity of the problem, transportation costs, defense activities, migrant population from the states, war department workers and dependents of military personnel.

B. Hospitals: Hospital facilities for the treatment of tuberculosis must be greatly expanded. A total of at least one thousand beds is essential. One hundred and twenty-five beds divided into units of approximately twenty-five beds each should be set up in conjunction with the present isolated Alaska Native Service facilities or other hospitals. Suggested sites are Bethel, Kotzebue, Unalakleet, Port Yukon and Nome. The unit would be used specifically for isolation and custodial care of patients with open cases of tuberculosis. These cases can be divided into (*a*) those awaiting transportation to sanatoriums, (*b*) suspect cases under observation for diagnosis and (*c*) those cases that are too advanced to be amenable to active treatment. In addition to present facilities six hundred and twenty-five beds adequately staffed and equipped to permit modern treatment of tuberculosis are required. These should be distributed as follows: One hundred additional beds in southeastern Alaska; four hundred beds in Anchorage, and one hundred beds in the arctic (Fairbanks is the suggested site). Two hundred and fifty beds are in existence at Sitka and Seward.

C. Immunization: It is recommended that an extended immunization program with BCG or a similar method be undertaken among the native population of Alaska.

4. *Eye Diseases.*—The incidence of corneal ulcers is so excessively high that steps should be taken to determine its exact cause in order that prevention and treatment may be intelligently undertaken.

The lack of a qualified ophthalmologist in the territory should be remedied.

5. *Venereal Disease Control.*—Incorporated communities must bring their police codes up to date, and proper enforcement of these codes must be insisted on to aid in the control of venereal diseases.

The federal government should assist the territory in the control of venereal disease. The sudden increase of the population due to defense work, railroad rehabilitation, armed forces in the territory and rapid influx of transient workers has made the problem too large for the territory to handle by itself.

The U. S. Public Health Service should supply the director of the Division of Communicable Diseases, under whose direction the control program for venereal disease as well as other communicable diseases, except tuberculosis, would be adequately supervised.

6. *Sanitation.*—The deplorable conditions of the essential sanitation facilities of all Alaskan communities must be corrected. Local governments have not been able

---

[1] The following are a few of the federal agency offices in Anchorage: Civil Aeronautics Authority; Veterans Administration; Weather Bureau; Alaska Railroad; Federal Bureau of Investigation; Fish and Wild Life; Land Management; Housing Authority; Rural Electrification; Department of Commerce; Post Office; Marine Division; U. S. Public Health Service, and War Assets Administration.

to cope with the problem, which has become acute because of the sudden increase of the population due to defense work, railroad rehabilitation, armed forces' dependents and migrations to the territory. The federal government has a responsibility in the establishment of improved water supplies, sewage disposal units and other sanitation facilities.

The sanitation problems in the arctic have not been entirely solved. The solutions are expensive and require outside assistance.

7. *Communicable Disease Control.*—The control of communicable disease is an increasing responsibility and difficult because of the increasing population. More federal responsibility in funds and personnel must be provided. There is the ever present threat of an epidemic which, if it were to occur, would endanger defense activities as well as the armed forces.

8. *Orthopedics.*—Federal aid to clean up the backlog of orthopedic cases, especially among the children, is urgently needed. The majority of the cases are among federal beneficiaries. Additional hospital facilities, as recommended herein, and professional personnel must be provided.

9. *Public Health Activities.*—The public health activities should be coordinated in that public health should be administered by the official agency (Territorial Department of Health) and hospitalization of federal beneficiaries should be administered by the Alaska Native Service. This may be accomplished over a five year period.

Such public health activities as the work of the *M/S Hygiene* and the mobile units (immunization, education, mass roentgenologic surveys and so forth) have included all elements of the population, but most of the work has been done for the natives. However, any activity of the Alaska Native Service precludes care to white persons or nonnatives.

The Territorial Department of Health is the recipient of federal funds such as tuberculosis control, crippled children and maternal and child health. The efficient administration of these benefits for the whole territory and for all of the population is best accomplished by the coordination of public health activities.

Public health nurses should be a cooperative activity between the Territorial Department of Health and the Alaska Native Service to the benefit of all. Contracts between the two agencies have been executed for such localities as Cordova, Sitka, Wrangell and Petersburg. More of this cooperation is recommended.

10. *Housing.*—In view of the deplorable status of housing and the very evident deleterious effects on health, immediate steps should be taken to remedy this situation. Because of the excessive costs of construction it is essential that the federal government take cognizance of and direct action to supply adequate funds for the solution of the problem.

11. *Arctic Institute.*—An Arctic Institute for the study of the Arctic and its bearing on health, sanitation, nutrition, engineering construction, food, clothing and footwear is recommended. This should be set up at the University of Alaska with federal funds, and it should coordinate the efforts of the armed forces and the various federal agencies. The resultant effects on the civilian economy of efficient means of heating, construction, sewage and water supply would be a boon to Alaskan development and defense.

Clinical Notes, Suggestions and New Instruments

LEUKOPENIA FOLLOWING THE USE OF PROPYLTHIOURACIL

WILLIAM J. EISENMENGER, M.D.
and
J. MURRAY STEELE, M.D.
New York

Propylthiouracil is generally conceded to be the least toxic antithyrotoxic agent at the moment. Serious reactions to this drug are almost lacking in the literature. Reports of two febrile and urticarial reactions in 129 cases[1] and of 1 case of leukopenia and sore throat in a series of 110 cases[2] have appeared. Astwood and VanderLaan have now treated over 100 patients without the development of any significant side effect.[3] In 260 patients treated with the drug at the Lahey Clinic depression of the white blood cell count has been noticed in 5 instances.[4] The development of pronounced leukopenia in a patient under treatment with this drug was therefore considered of sufficient importance to report.

A second point of interest in the case is the increasing degree of thyrotoxicosis that developed while propylthiouracil was being administered in what was thought to be an adequate maintenance dose.

REPORT OF CASE

A woman aged 65, a housewife, was admitted to this hospital on Feb. 3, 1946 with a chief complaint of weakness of four years' duration, which had become so extreme in the six weeks prior to admission that she was not able to walk or stand unsupported. She had also progressively lost 56 pounds (25 Kg.) in weight (170 to 114 pounds) during the previous year. For a period of six months she had noted excessive diaphoresis and a thinning of the texture of her hair. She had not been nervous or irritable, nor had she suffered palpitation or gastrointestinal symptoms.

Physical examination revealed a short, elderly woman with evidence of considerable recent loss of weight. Tremor and diaphoresis were absent. The common eye signs of thyrotoxicosis were lacking. There was a fulness in the suprasternal notch and a shift of the larynx and trachea to the left. A large mass of thyroid gland at the base of the neck on the right side extended downward into the superior mediastinum. A hard nodule 2 cm. in diameter was felt in the midst of this mass. The heart was moderately enlarged, the apical impulse being in the sixth left intercostal space, just outside the midclavicular line. The blood pressure was 170 systolic and 60 diastolic in mm. of mercury, and the pulse rate was 80. Normal sinus rhythm was present. Roentgen examination confirmed the impression of substernal extension of an enlarged thyroid gland. The basal metabolic rate was plus 54 per cent. The blood serum cholesterol determination was 173 mg. per hundred cubic centimeters. The hemoglobin level and the red blood cell count were normal, and the leukocytes ranged around 7,000 per cubic millimeter, with 65 per cent polymorphonuclear cells.

Because surgical removal of the thyroid appeared difficult, a trial of chemotherapy was decided on. Thiouracil, 0.1 Gm. four times a day, was administered, and the dose was reduced after one month to 0.1 Gm. twice a day, because the basal rate of the patient had fallen to nearly normal levels. In the

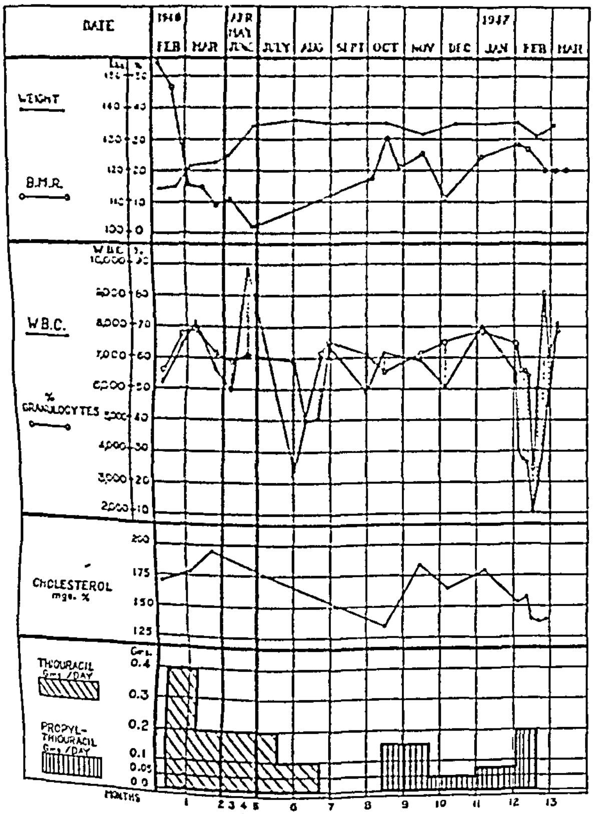
outpatient department this dosage was continued for four months and then further reduced to 0.1 Gm. a day for one month. At this point, because the white blood cell count was low (3,400) and a differential count showed only 40 per cent polymorphonuclear cells, the administration of thiouracil was discontinued. There was a prompt return of the blood count to normal levels, as shown in the accompanying chart.

During this six month period of thiouracil therapy the patient had been doing well, as shown by her gain in weight and the return to normal of basal metabolic rates. However, within two months of the cessation of thiouracil therapy (October 1946) her basal metabolic rate rose to plus 30 per cent, the serum cholesterol level fell to 126 mg. per hundred cubic centimeters and, most important, she experienced her first episode of auricular fibrillation. Slight dyspnea occurred with this attack, but signs of congestive cardiac failure did not develop. The leukocyte and differential counts were normal at this time.



Laboratory Data

Because of the development of leukopenia on thiouracil she was put on a regimen of propylthiouracil, 50 mg. three times a day. During the next month another episode of auricular fibrillation occurred. As her serum cholesterol reading rose from 126 to 186 mg. per hundred cubic centimeters and her basal metabolic rate decreased, the dosage was reduced from 150 to 50 mg. a day. She remained on this regimen for six weeks until, in January 1947, a rising metabolic rate prompted an increase in the dosage to 75 mg. a day. After one month on this dosage she began to complain of exertional dyspnea and frequent episodes of irregular rhythm of the heart. Electrocardiograms showed that auricular fibrillation was present. The patient was hospitalized again, and normal sinus rhythm returned. The serum cholesterol determination had dropped to 150 mg. per hundred cubic centimeters, and the basal metabolic rate had risen to plus 29 per cent. Leukocyte counts remained at normal levels (6,000) with a normal differential count (65 per cent polymorphonuclear leukocytes).

The patient apparently exhibited signs of progressive thyrotoxicosis while receiving moderate doses of propylthiouracil for over three months. The dosage was increased to 50 mg. four times a day on Feb. 2, 1947, but symptomatic improvement did not occur. In fact, the serum cholesterol reading dropped further (to 135 mg. per hundred cubic centimeters), and the patient continued to lose weight. The white blood count fell steadily to 2,100 cells per cubic millimeter, associated with a sharp drop in polymorphonuclear cells to 22 per cent of the total count.

In view of the failure of the propylthiouracil to maintain the patient in adequate control on the usual dose, but more especially because of the danger of a continued fall in the number of granulocytes, administration of the drug was discontinued and surgical removal of the gland was recommended. On discontinuance of propylthiouracil the leukocytes rose quickly to a level of 8,000, the main rise taking place in the number of granulocytes, which rose rapidly from 22 to 82 per cent of the total leukocyte count.

The patient was prepared for surgical intervention by being given strong solution of iodine U. S. P. 10 drops three times a day for two weeks, without significant change in her basal metabolic rate and serum cholesterol level Quinidine sulfate, 0.2 Gm. three times a day, was also given in an effort to prevent auricular fibrillation. A massive right lobe of the thyroid gland was then removed, and the relatively small left lobe was left. The operative procedure and the immediate postoperative course were uneventful except for several short bouts of auricular fibrillation.

SUMMARY AND CONCLUSION

A case of thyrotoxicosis due to a large nodular goiter treated with thiouracil for six months and propylthiouracil for four months is reported because of reactions which appeared on use of these drugs.

1. Mild leukopenia developed after six months on thiouracil therapy.
2. Severe leukopenia developed after four months of treatment with propylthiouracil. Seventy-five milligrams of the drug a day proved insufficient to control the basal metabolic rate. During a short period of administration of 200 mg. of the drug a day in an unsuccessful effort to control the disease, leukopenia developed.

Council on Foods and Nutrition

ACCEPTED JUICES

In order to encourage the production of fruit juices containing high natural levels of vitamin C, the Council on Foods and Nutrition accepts orange juice in which at least 40 mg. of ascorbic acid per hundred cubic centimeters of juice is conserved.

Attention is called to the fact that the products listed in this issue are not heat treated and should be consumed promptly after removal from refrigeration.

The following products meet the standards and rules established by the Council for fruit juices.

James R. Wilson, M.D., *Secretary.*

The Vacuum Foods Corporation, Plymouth, Fla.

Minute Maid Brand Quick-Frozen Concentrated Orange Juice (27 fluidounces, 799 cc.).

Snow Crop Brand Quick-Frozen Concentrated Orange Juice (5⅜ fluidounces, 159 cc.).

These products, identical in composition, are distributed in containers of two sizes, namely, 27 fluidounces for institutions and 5⅜ fluidounces for individual use.

Analysis (submitted by manufacturer).—The analysis of the concentrate and of the product as reconstituted by the addition of three parts of water is as follows:

	Concentrate	1 + 3 Dilution
Total solids, %	38.52	10.810
Moisture (by difference), %	61.48	89.190
Protein (N × 6.25), %	1.75	0.490
Fat (ether extract), %	0.09	0.030
Crude fiber, %	0.07	0.020
Carbohydrates, %	35.05	9.830
Ash, %	1.56	0.440
Calories, per gram	1.52	0.426
Ascorbic acid, mg. per 100 Gm.	159.30	44.700

SATURDAY, OCTOBER 25, 1947

THE EFFECTS OF MINERAL OIL

The use of mineral oil in foods such as imitation mayonnaise or salad dressing increased during the war because of the shortage of biologic fats and oils.[1] Such food substitutes are used extensively also in weight-reducing diets. Previous reports concerning the interference of mineral oil with the absorption of fat-soluble vitamins, particularly vitamin A and its precursor, carotene, were based mostly on animal experiments in which large quantities of mineral oil were used, compared with what would ordinarily be taken by man. Curtis[2] and his associates showed that the ingestion of mineral oil by human beings will prevent a rise in blood carotene consequent to simultaneous intake of foods rich in carotene; the subjects in this experiment were observed for only fifteen days. Recently Alexander[1] and his associates made similar observations on human beings for three to eight weeks. Group 1 did not take mineral oil. Group 2 took 1 tablespoonful of a product containing 83 per cent mineral oil and 2 per cent fat with the noon and evening meal daily. Group 3 took 1½ teaspoonfuls of the same product with noon and evening meals daily. Group 4 took 1 tablespoonful of mineral oil with noon and evening meals. Group 5 comprised 9 patients with psoriasis vulgaris, of whom 6 took 1 tablespoonful of mineral oil with noon and evening meals and 3 took 1 tablespoonful with each of the three meals. The diets of all subjects were unrestricted. The plasma carotene and vitamin A concentrations were determined by Kimble's method at frequent intervals. The results indicated that concomitant with the prolonged daily ingestion of mineral oil, either as such or in the form of mayonnaise dressing at meal time, the plasma carotene concentration decreased about 50 per cent. The decline was about the same for those using 2 tablespoonfuls as for those using 3 teaspoonfuls, and differences were not observed between those using regular mineral oil and those using the product previously mentioned. The decrease in plasma carotene was noted within one to two weeks; it progressed further in many cases as the intake of mineral oil continued. Neither significant changes in the plasma vitamin A nor untoward clinical manifestations occurred. Since it is well known that the concentration of vitamin A in the blood remains relatively constant for as long as six months in normal persons subjected to restricted intake of vitamin A and carotene, a conclusion could not be drawn on these subjects with regard to the effect of mineral oil on the supply of vitamin A as such to the body. The conclusion, however, was that in man the simultaneous ingestion of mineral oil with food prevents substantial amounts of food carotene, a precursor of vitamin A, from entering the body.

While many physicians believe that mineral oil is not absorbable and therefore can do no harm, some of it prescribed for constipation does pass through the intestinal wall and on into the liver. Alvarez[3] reviewed the work of Frazer, Stewart and Schulman, who found that if mineral oil was ingested without previous emulsification only a small percentage of it was absorbed but that when given in the form of a fine emulsion, as many persons take it, about one half of it went through the wall of the bowel. These workers found also that the fine emulsification necessary for this process could be effected by a combination of bile salts, oleic acid and glyceryl monostearate which can be found in the bowel. When taken in the form of the clear oil much of it is emulsified in the stomach or bowel. Frazer and associates demonstrated such absorption through the intestinal mucosa of rats histologically, biochemically and by actually counting the tiny oil droplets found in the blood, which could be easily seen in the cells of the intestinal wall. With a special chemical technic they found that from 35 to 60 per cent of the amount of emulsified oil was absorbed, an amount comparing favorably with the percentage of olive oil absorbed in control experiments. Stryker found in various experimental animals that the extent to which lesions appeared in the liver and lymph nodes was related to the time the animals had been given mineral oil. Rabbits fed mineral oil more than seven months showed numerous tiny white nodules in their intestinal wall, and vacuolization appeared in the mesenteric lymph nodes and liver. Similar changes were found in the tissues of men and women who were known to have used paraffin oil; in fact in 15 of 25 consecutive necropsies the lymph nodes revealed the presence of such droplets of oil.

---

[3] Alvarez, W. C.: The Absorption of Hydrocarbon Oil in the Small Intestine, Gastroenterology **9**: 315-317 (Sept.) 1947.

These observations raise the grave question, Alvarez says, whether mineral oil can be used safely, year in and year out, as some persons use it; they also raise the question whether purveyors of food should ever be allowed to substitute mineral oil for the edible fats. The Council on Foods and Nutrition of the American Medical Association concluded in a report[4] published in 1943 that the indiscriminate use of mineral oil in foods and cooking is not in the interest of good nutrition and that any such use should be under careful supervision of a physician.

THE PROBLEM OF CEREBRAL PALSY

The Joint Legislative Committee appointed by the legislature of the state of New York[1] to study cerebral palsy has made a preliminary report indicating that less assistance has been given to those with cerebral palsy than to the blind, the deaf and the crippled. At least 10,000 persons have this disability in New York.

Older writers considered birth trauma including cerebral hemorrhage, asphyxia or circulatory interference the most important causative factor of cerebral palsy. Recent investigations, however, support the original statement of Little that "the condition may present itself as a congenital affliction or as a result of diseases during infancy. Cerebral palsy is probably in most cases the result of variations in the structure of the brain." The abnormality may vary from the slightest physical handicap to subnormal mentality and severe physical disability with inability to meet the simplest personal needs. The misconception that the mental development of the patient with cerebral palsy is necessarily retarded needs correction. As a matter of fact, mentality is normal in most instances; whatever mental retardation is present is due to a lesion of the area of the brain concerned with the development of intelligence. This occurs in a limited percentage of patients.

Diagnoses of mental deficiency are made frequently because of the patient's appearance and poor score on psychometric testing, although accuracy in such tests depends on proper coordination, normal speech and good vision and hearing. The report points out that the evaluation of the extent of physical and mental retardation is difficult even when the diagnosis of the condition is almost self evident. Evaluation requires determination of the type of qualitative motor defect, the degree of handicap, the parts of the body involved, the amount of involvement, the developmental progress that has been made, the presence of associated or independent defects and the social situation of the patient and the patient's family.

Proper diagnosis of cerebral palsy depends on the training of more medical specialists supplemented by psychologic examiners and specially devised testing and diagnostic procedures which are capable of reaching the real person through the mask of physical handicaps which stand between him and the examiner.

Treatment cannot eradicate the original lesion. Specific treatment can be given for some of the defects, but the patient must be trained rather than treated. Whatever latent resources he possesses can be activated to the fullest extent. Training consists primarily of physical and occupational therapy to help the patient achieve better coordination of movements, to control hyperactive movements and to overcome involuntary movements through relaxation and similar functions.

Specialists estimate that 65 to 70 per cent of patients with cerebral palsy have normal mentality. Improvement in such patients extends from simply acquiring the capacity to dress and feed themselves to complete vocational rehabilitation.

Children and adults with cerebral palsy are entitled to the same educational services under the laws of the state of New York as are provided for other physically handicapped persons. The State Department of Education is authorized to provide vocational education and training, maintenance, textbooks and supplies and orthopedic appliances to the physically handicapped in order to prepare them for useful employment. However, the report stresses that the total of specialized treatment now available is small in proportion to the need. For most of those with cerebral palsy thorough and specialized diagnosis is not available. A survey by the Children's Bureau, then of the United States Department of Labor, published July 15, 1946, revealed that little progress has been made in the various states in meeting the needs of children with cerebral palsy. Medical, surgical and therapeutic services for such children are either absent or inadequate, both as to the number of children reached and the scope of services.

The report of the Legislative Committee emphasizes that the situation is rapidly improving. The programs in several states includes special institutions, appropriations for specialized centers in connection with state university medical schools and state subsidization of services from private institutions. States have met the problem in different ways. The report suggests the general objectives to be sought in attempting to develop a program for New York. Private interest in this problem is needed to supplement the work of the state in the care of so many other groups of the unfortunate.

World Medical Association

Note: Following is a report by Dr. Charles Hill, secretary of the British Medical Association, of the first meeting of the World Medical Association in Paris, September 18. Dr. Hill is honorary secretary of the World Medical Association pending the establishment of a permanent office and the appointment of a full time secretary. Dr. J. A. Bustamante of Havana, Cuba, secretary of the Pan-American Medical Confederation, was appointed as honorary assistant secretary for matters pertaining to the Latin American countries.—Ed.

CONSTITUTION

During the first part of the meeting, which took the form of a conference of representatives of national medical associations, various amendments were made in the draft articles and by-laws, which will now be revised in accordance with the decisions of the conference and issued with the minutes. When the constitution, thus amended, was adopted by the conference, it was formally declared that:

> In the city of Paris at 3:40 p.m., on September 18, 1947, the World Medical Association came into being.

The meeting then became the first annual meeting of the general assembly, and Professor Eugène Marquis (France) was installed as the first president of the association.

Dr. Charles Hill (Great Britain) was appointed acting honorary secretary of the meeting.

HEADQUARTERS

It was decided that the offices of the Association should be situated in North America, the exact location being left for decision by the council. One of the main factors influencing this decision was the desirability of close and constant contact with the United Nations and World Health organizations (U. N. O. and W. H. O.) which have their headquarters in New York.

OFFER OF FUNDS FROM THE UNITED STATES

The delegates from the United States reported that certain industrial "friends of the American Medical Association," being convinced of the potential value of the World Medical Association to medicine and to the promotion of world peace and being desirous of helping to establish it on a sound financial basis, had offered to guarantee an income of $50,000 for the first year and, if necessary, to continue a similar contribution for a further four years. The money was intended to be used for the provision of a permanent office, the remuneration of a full time secretary and staff and the running costs of the secretariat. An American committee of physicians and laymen had been set up to administer the funds. The American delegates emphasized that there was no intention of determining or interfering with the policy of the World Medical Association, the committee's only duty being to approve the general purpose of the projects for which the Association desired to use the donors' money. After a prolonged discussion the association decided by a majority vote to accept the generous offer of its American friends and adopted the following resolutions:

Resolved, That the general assembly accept with gratitude the offer of the friends of the American Medical Association and place on record its deep appreciation of their generosity in making available funds sufficient for the establishment of the World Medical Association on a satisfactory basis.

That the funds thus made available be utilized to defray expenditure under the following headings: (*a*) the remuneration and expenses of the secretary, other officials and clerical staff; (*b*) the rent, rates and other disbursements in connection with the official headquarters; (*c*) the general office expenses of the headquarters office staff; (*d*) the cost of the publication of the association's official bulletin or journal, and (*e*) the traveling costs of the council.

That the cost of the developments previously listed be estimated at not more than $50,000 for the first year.

That the Council be authorized to act on the assembly's behalf in appointing the secretary of the World Medical Association and to make all other staffing arrangements, regional and other.

That the Council be instructed to explore the possibility of making arrangements for gift funds to the World Medical Association to be made tax-free.

That member associations be recommended to consider the formation of World Medical Association supporting committees in their several countries.

That the council be authorized to prepare plans of development, to enter into any necessary consultations and to submit its proposals to the general assembly.

That nothing in these resolutions shall diminish the authority of the general assembly for the full control of the policy and affairs of the Association as provided in article 8.

SUBSCRIPTION

The acceptance of the American offer does not, of course, relieve the association of the necessity of collecting its own subscription income. After consideration of the report of the honorary treasurer and of the possible methods of assessing subscriptions, the general assembly adopted the following resolutions:

Resolved, That the subscription of each member association be calculated at a flat rate per member with a minimum total and a maximum total, and that the flat rate per member be 20 Swiss centimes, with a minimum of 1,000 Swiss francs and a maximum of 10,000 Swiss francs.

MEMBERSHIP ROLL

In accordance with article 5 (I) those national medical associations which were represented at the London conference in September 1946 were accepted as founder members. During 1946-1947 the Organizing Committee, which was instructed by the conference to proceed with the organization of the association, invited all national medical associations to apply for membership, and those applicants which appeared to fulfil the conditions of article 5 (II) were accepted as members.

As soon as the constitution was adopted at the Paris meeting, the procedure laid down in by-law 1 came into operation. Italy (La Federazione Nazionale degli Ordini dei Medici Italiani) made a written application for membership to the general assembly and was accepted. Certain difficulties then arose in connection with the associations in Latin America, and the general assembly eventually decided to request the council to submit for examination by next year's general assembly the applications of all member associations.

SECRETARIAT

As has already been stated, the general assembly left to the council the problem of the general organization of the secretariat. However, it considered the desire expressed by the Latin American associations for the specific recognition of the Spanish culture in the association's organization. They proposed the adoption of Spanish as a third official language and the appointment of a Spanish assistant secretary, whom they offered to finance without cost to the association. The assembly adopted the first proposal. With regard to the second, it recognized that with the development of the association's work it might become desirable to appoint perhaps several assistant secretaries in different parts of the world. It therefore instructed the council to include this matter in its consideration of the general organization of the secretariat and recommended for acceptance the kind offer of the Latin American associations.

PROXY VOTING IN ASSEMBLY

The general assembly referred to the council for consideration a suggestion by Australia that provision should be made in the by-laws for voting by proxy in the general assembly in order that far distant member associations which might be unable to send delegates to a meeting of the general assembly would not thereby lose their voting power.

WAR CRIMES

After a discussion of the motions on the agenda by Denmark and Great Britain and the British memorandum relating to the attitude of the members of the medical profession toward war crimes, and after hearing statements by members of the assembly and by a French medical victim of war crimes, the assembly appointed a small committee to formulate a recommendation. The following report of the committee was subsequently adopted by the assembly:

Resolved, That a report on crimes committed since 1933 by physicians and medical organizations in Germany and other countries and on this violation of the medical ethic be prepared and made available to physicians throughout the world.

That the World Medical Association solemnly condemns the crimes against human beings committed by certain members of the medical profession such as are described in the British memorandum.

That every doctor, at the time of receiving his medical degree or diploma, be required to subscribe to the following oath

> "My first duty, above all other duties, written or unwritten, shall be to care to the best of my ability for any person who is entrusted or entrusts himself to me, to respect his moral liberty, to resist any ill treatment that may be inflicted on him and, in this connection, to refuse my consent to any authority that requires me to ill treat him.
>
> Whether my patient be my friend or my enemy, even in time of war or in internal disturbances, and whatever may be his opinions, his race, his party, his social class, his country or his religion, my treatment and my respect for his human dignity will be unaffected by such factors."

That the World Medical Association endorse judicial action by which members of the medical profession who shared in war crimes are punished.

That the World Medical Association request the German medical syndicates to make the following public declaration

> A. We, members of the German medical syndicate, are aware of the very large number of acts of cruelty committed, both by individuals and collectively, since 1933 in mental hospitals and in concentration camps and of the violation of the medical ethic. These acts have resulted in the death of some millions of persons. A large number of our members have been implicated in these acts, either as instigators or as technical agents or as actual perpetrators.
>
> B. We regret that the organized medical profession in Germany has not made any protest and has been content to ignore these acts, of which it could not have been unaware.
>
> C. We undertake solemnly to condemn these crimes, to expel from our organization the criminals who have committed them and to remind all our members of the respect due not only to life but to human personality, dignity and liberty.

The assembly instructed the council to prepare a report incorporating these resolutions and also to take into consideration the following motion by the Netherlands: "That the council be instructed to prepare a report on the collaboration of medical practitioners in the preparation of means of warfare."

MATTERS REFERRED TO COUNCIL

During the course of the meeting the general assembly also referred the following matters to the council for appropriate action or investigation and report:

1. The general arrangements for the organization and publication of a bulletin or journal.

2. The preparation of a report on the inquiry into the present position of the medical profession in relation to the state.

3. The motions of Luxembourg, supported by Australia, recommending the preparation (*a*) of a comparative statement on standards of training for the medical profession and conditions of registration and (*b*) of a comparative statement on the qualifications of specialists.

4. The following motions by India: (*a*) "That the council be requested to study and report on the question of the advertisement of cures and medicines in the lay press" and (*b*) "That the council be requested to study and report on the question of unqualified and unauthorized medical practice."

5. The preparation of standing orders to govern the procedure of meetings of the general assembly.

6. The appointment of auditors.

SECOND ANNUAL MEETING OF GENERAL ASSEMBLY 1948

The general assembly decided to hold its 1948 meeting in Prague, Czechoslovakia, the exact date being left to the council to decide.

PRESIDENT-ELECT, 1947-1948

The general assembly elected Dr. J. Stucklich (Czechoslovakia) to preside over its annual meeting in 1948. He therefore becomes president-elect for the year 1947-1948.

TREASURER, 1947-1950

The general assembly elected Dr. O. Leuch (Switzerland) as treasurer of the Association for the period of 1947-1950.

COUNCIL, 1947-1948

The general assembly elected the first council. Dr. Zahor (Czechoslovakia) and Dr. Glorieux (Belgium) having resigned after election, the council for 1947-1948 is composed as follows: president ex officio, Professor E. Marquis, France; president-elect, Dr. J. Stucklich, Czechoslovakia; treasurer, Dr. O. Leuch, Switzerland; chairman, Dr. T. C. Routley, Canada, and vice chairman, Dr. D. Knutson, Sweden. Other members of the council are Drs. L. H. Bauer, United States; J. A. Bustamante, Cuba; P. Cibrie, France; A. Hartwich, Austria; P. Z. King, China; J. A. Pridham, Great Britain; S. C. Sen, India, and L. G. Tornel, Spain.

At the conclusion of the general assembly's proceedings the council held its first meeting.

Pending the establishment of a permanent office and the appointment of a full time secretary, the council appointed Dr. Charles Hill (Great Britain) as honorary secretary of the association with temporary headquarters at B. M. A. House, London.

Washington Letter

(From a Special Correspondent)

Oct. 23, 1947.

Funds for New Army Medical Library

Brig. Gen. George E. Armstrong, acting surgeon general of the Army, told the fourth annual meeting of the honorary consultants to the Army Medical Library that the War Department would again request funds from Congress next year for a new building. Cost is estimated around $16,000,000, four times the amount sought nine years ago. Congress will have to amend existing enabling legislation before an appropriation can be requested. Col. Joseph H. McNinch, library director, reported that the present building at Seventh Street and Independence Avenue, S.W., is inadequate. He said that one of the library's greatest needs is a permanent director. At present, Army officers are appointed to the post every four years. General Armstrong explained that the War Department already is planning to acquire a career director. Among other speakers were: Gen. Paul R. Hawley, medical director of the Veterans Administration; Walton B. McDaniel, librarian, Philadelphia College of Physicians, and Chauncey D. Leake, dean of the University of Texas School of Medicine. New officers elected were: president, Dr. Leake; vice president, Wilburt C. Davison, Raleigh, N. C., dean of Duke University School of Medicine, and secretary-treasurer, reelected, Col. Harold W. Jones, M. C., U. S. Army, retired. Dr. Reginald Fitz, Boston, medical history lecturer, Harvard University, was appointed to the executive committee.

Health Service Announces Cancer Research Grants of $363,749

The U. S. Public Health Service has announced that grants totaling $363,749 have been made to nearly a score of colleges and other institutions for cancer research and control. They are part of the $14,000,000 campaign against cancer authorized by Congress for the fiscal year ending next June 30. The projects were recommended by Dr. A. V. Deibert of the National Cancer Institute and approved by the National Advisory Cancer Council. The grants include research for improved cancer instruction technics, a national survey of cancer clinics, evaluation of different cancer control and detection methods and fundamental studies of the growth, development and treatment of cell malignancies. A joint Public Health Service and District of Columbia survey revealed that Washington has the highest cancer incidence of twelve cities surveyed.

Dr. Paul B. Magnuson Takes Number Two Spot in Veterans Administration

Dr. Paul B. Magnuson, Chicago surgeon who helped set up the Dean's Committee program which links Veterans Administration hospitals with the nation's best medical centers, has been appointed chief of professional services for the Veterans Administration Medical Department. This is the number two position. In the event that Dr. Hawley succeeds Gen. Omar Bradley as head of the agency when the latter is appointed Army Chief of Staff, Dr. Magnuson will be in line for the medical directorship. Dr. Magnuson succeeds the late Brig. Gen. Elliott C. Cutler, who died last August in Boston.

mittee that is carrying on the recruitment program hopes to be able to get 50,000 or 60,000 student nurses this year. The general impression around the country is that there will be more student nurses than there were last year.

In connection with the problem of the nurse shortage, there has been a great deal of discussion as to the desirability of producing more practical nurses. The professional nurses have raised their educational standards and perhaps are getting themselves out of bedside nursing. In Michigan the State Board of Education, in cooperation with the nursing organizations, has outlined a program by which six practical nurse training centers will be established in the larger cities patterned after a similar project that has been going on in Detroit for a number of years. These practical nurses will be recruited from the senior students in high schools. The teachers will be registered nurses on the high school faculties. We expect to start this program when the schools open in the fall. This is a part of the vocational education system. Under this program standards for practical nursing service will be established. It is considered that this type of nurse will be able to do from 80 to 90 per cent of the ordinary bedside nursing in hospitals.

A development which should receive consideration is the matter of the universities beginning to take over the education of registered nurses.

REPORT OF SUBCOMMITTEE ON SPECIALTY BOARD FOR GENERAL PRACTITIONERS—CONTINUED

Drs. Bierring and Sensenich, members of the Subcommittee, and Miss Switzer, whose consultation they had requested, returned to the meeting and submitted the following report, which was adopted unanimously:

> The Joint Committee for the Coordination of Medical Activities desires to record its recognition of the distinct contribution of specialty boards to the elevation of medical standards and the quality of medical practice in this country. However, the growing tendency to exclude the general practitioner from hospital staff privileges is having the effect of making it impossible for the general practitioner to secure the advantages of modern hospital facilities for the treatment of his patients. This is true in spite of the fact that by far the largest group of patients in the country relies on the general practitioner for medical services.
>
> The Committee feels that there is need for a better understanding of the role of the general practitioner in medical service and, therefore, recommends a long range program on the part of all professional bodies concerned to this end.
>
> The Committee does not believe the setting up of a specialty board for general practice meets the need at this time. However, there is immediate need for the integration of general practitioners into the hospital staffs throughout this country, and to accomplish this the Committee recommends that the Council on Medical Education and Hospitals of the American Medical Association develop as soon as possible several alternate plans.
>
> The Committee further recommends that the American Medical Association and other professional organizations, as well as the national hospital associations, in their regional and annual meetings and in their publications give prominent place to a discussion of how this hospital staff integration can best be accomplished in order to make available for each eligible physician and his patients all the facilities provided for medical care in the community.

Mr. Davis discussed the subject as follows: With respect to the responsibility of the hospitals, I think it would be the general policy of the American Hospital Association to say that every reputable physician should have a hospital staff appointment. It seems to me that the whole problem at the present time stems from the fact that there is a maldistribution of physicians and also a shortage of hospital beds, particularly in the big cities. The physicians coming back from military service are crowding into the large cities, and that is where the problem exists. It does not exist outside the metropolitan areas. Hundreds of hospitals in this country have no specialists on their staffs. There is a hospital in Michigan where there are only two specialists, and the general practitioners are keeping out the specialists. A person who gets into a hospital ordinarily needs a specialist. The hospitals are confronted with the problem of providing to the public the highest possible quality of service.

REPORT FROM LIAISON REPRESENTATIVE OF OFFICE OF THE SURGEON GENERAL

Colonel Armstrong brought to the attention of the Committee correspondence with young physicians, graduates of the Army Specialized Training Program, who are now in service. He said the letters follow a familiar pattern complaining about foreign duty, about lack of rotation between tactical units and hospitals and about the deferment of presently interning A. S. T. P. men when the writers are being held in service twenty-four months. Basically, he said, they reflect the fact that anything which has to do with military service at the moment is not popular.

Colonel Armstrong continued: These men cannot understand that they can learn something from sick call duty; those who are the least unhappy are those who are in a teaching hospital *with a "Board" man as chief; some of the letters are from* Korea, and many of the complaints from that theater are justifiable; General MacArthur has promised to investigate; the trouble is recognized and steps are being taken to correct it. The Office of the Surgeon General is "surplusing" every day; a check is kept on all theaters to see that the surplus is sent back.

The Chairman thanked Colonel Armstrong for his presentation.

AMERICAN RED CROSS BLOOD BANK PROGRAM

Dr. Draper presented information concerning the Red Cross Blood Bank Program.

TIME AND PLACE OF NEXT MEETING

It was voted to hold the next meeting at American Medical Association Headquarters in Chicago on Saturday morning, Aug. 16, 1947.

Coming Medical Meetings

Conference of State Medical Society Secretaries and Editors, Chicago, A.M.A. Headquarters, Nov. 7-8. Dr. George F. Lull, 535 N. Dearborn St., Chicago 10, Secretary.

American Academy of Allergy, St. Louis, Hotel Jefferson, Dec. 15-17. Dr. Theodore L. Squier, 425 E. Wisconsin Ave., Milwaukee 2, Secretary.

American Academy of Dermatology and Syphilology, Chicago, Palmer House, Dec. 7-11. Dr. Earl D. Osborne, 471 Delaware Ave., Buffalo, N. Y., Secretary.

American Academy of Pediatrics, Dallas, Texas, Dec. 8-11. Dr. Clifford G. Grulee, 636 Church St., Evanston, Ill., Secretary.

American Association of Railway Surgeons, Chicago, Nov. 23-25. Dr. Raymond B. Kepner, 547 West Jackson Boulevard, Chicago 6, Secretary.

American Otorhinologic Society for the Advancement of Plastic and Reconstructive Surgery, New York, Nov. 13. Dr. Norman N. Smith, 291 Whitney Ave., New Haven 11, Conn., Secretary.

American Society for the Study of Arteriosclerosis, Chicago, Hotel Knickerbocker, Nov. 2-3. Dr. O. J. Pollak, Wilmington General Hospital, Wilmington 14, Delaware, Secretary.

American Society of Anesthesiologists, New York, Hotel New Yorker, Dec. 4-5. Dr. Curtiss B. Hickcox, 745 Fifth Ave., Room 1503, New York 22, Secretary.

American Society of Clinical Pathologists, Chicago, Drake Hotel, Oct. 28-30. Dr. A. S. Giordano, 531 N. Main St., South Bend, Ind., Secretary.

American Society of Tropical Medicine, Atlanta, Ga., Dec. 2-4. Dr. Norman H. Topping, National Institute of Health, Bethesda 14, Md., Secretary.

Association of American Medical Colleges, Sun Valley, Idaho, Oct. 27-29. Dr. Fred C. Zapffe, 5 S. Wabash Ave., Chicago, Secretary.

Association of Military Surgeons of the United States, Boston, Hotel Statler, Nov. 13-15. Col. James M. Phalen, Army Medical Museum, Washington 25, D. C., Secretary.

Central Society for Clinical Research, Chicago, Drake Hotel, Oct. 30-Nov. 1. Dr. Ford K. Hick, 25 E. Washington St., Chicago 2, Secretary.

Indiana State Medical Association, French Lick, Oct. 28-30. Mr. Ray E. Smith, 23 E. Ohio St., Indianapolis 4, Executive Secretary.

New England Postgraduate Assembly, Boston, Copley-Plaza Hotel, Oct. 29-31. Dr. Leroy E. Parkins, 8 Fenway, Boston 15, Chairman.

New York State Association of Public Health Laboratories, Albany, Nov. 7. Miss M. B. Kirkbride, New Scotland Ave., Albany 1, Secretary.

Oklahoma City Clinical Society, Oklahoma City, Biltmore Hotel, Oct. 27-30. Dr. Elmer R. Musick, 512 Medical Arts Bldg., Oklahoma City, Director of Clinics.

Omaha Mid-West Clinical Society, Omaha, Oct. 27-31. Dr. John M. Thomas, 1031 Medical Arts Bldg., Omaha 2, Secretary and Director of Clinics.

Post Graduate Medical Assembly of South Texas, Houston, Texas, Coliseum, Dec. 1-3. Dr. E. Trowbridge Wolf, 229 Medical Arts Bldg., Houston, Texas, Secretary.

Puerto Rico, Medical Association of, San Juan, Dec. 10-14. Dr. Jeramfel Cordero, Box 3866, Santurce, Secretary.

Radiological Society of North America, Boston, Nov. 30-Dec. 5. Dr. Donald S. Childs, 607 Medical Arts Bldg., Syracuse 2, N. Y., Secretary.

Seaboard Medical Association of Virginia and North Carolina, Virginia Beach, Va., Dec. 2-5. Dr. Clarence Porter Jones, 3117 West Ave., Newport News, Va., Secretary.

Southern Medical Association, Baltimore, Nov. 24-27. Mr. C. P. Loranz, Empire Bldg., Birmingham 3, Ala., Secretary.

Southwestern Medical Association, Phoenix, Ariz., Hotel Westward Ho, Nov. 6-8. Dr. Louis W. Breck, 116 Mills St., El Paso, Texas, Secretary.

Southern Surgical Association, Hollywood, Fla., Dec. 9-11. Dr. Alfred Blalock, Johns Hopkins Hospital, Baltimore 5, Secretary.

Western Surgical Association, Colorado Springs, Broadmoor Hotel, Dec. 4-6. Dr. Warren H. Cole, 1853 West Polk St., Chicago 12, Secretary.

GOVERNMENT SERVICES

VETERANS ADMINISTRATION

INTENSIVE RESEARCH ON HEART DISEASE

The Veterans Administration announces that intensive research in heart disease will be centered at the Mount Alto Hospital in Washington, D. C. The new research center, a part of which is already in operation, will conduct investigations on cardiovascular physiology and pathology for the primary purpose of improving the treatment of veterans. It will serve also as a training center for physicians by providing graduate study and resident training for certification by the American Board of Internal Medicine. The new center will provide consultation service in cardiovascular disease. The center will have the following eight major functions: treatment, clinical research, cardiovascular roentgenography, cardiac catheterization and hemodynamics, electrocardiography, pathology, statistical research and postgraduate teaching; later departments for research in biochemistry and biophysics will be added. The research center was developed under the supervision of Dr. George P. Robb, assistant medical director of the Metropolitan Life Insurance Company, who will continue as consultant to the cardiovascular research unit. Dr Robb, a graduate of Indiana University School of Medicine, has conducted research projects at Harvard Medical School and New York University College of Medicine and during World War II was chief of the cardiovascular and electrocardiographic departments of Walter Reed General Hospital, Washington, D. C.

DR. MAGNUSON APPOINTED CHIEF OF PROFESSIONAL SERVICES

The Veterans Administration announces the appointment of Dr. Paul B. Magnuson, Chicago, as acting chief of its Professional Services to succeed the late Brig. Gen. Elliott C. Cutler, who died August 16. Dr. Magnuson, formerly chairman, Department of Bone and Joint Surgery, Northwestern University Medical School, Chicago, came to the Veterans Administration in November 1945 on leave from Northwestern to assist the medical director in the reorganization of medical care for veterans. He has been with the Veterans Administration since then as acting chief of the Research and Education Service and will be succeeded in that position by Dr. Edward H. Cushing, former associate clinical professor of medicine, Western Reserve University, Cleveland, who has been associated with Dr. Magnuson as chief in that work.

PUBLIC HEALTH SERVICE

CANCER RESEARCH AND STUDY PROJECTS

The U. S. Public Health Service announced October 8 the award of more than $375,000 in grants for special research and study on improving technics for professional cancer instruction, a nationwide survey of cancer clinics and evaluation of cancer control measures. These awards, a part of the $14,000,000 cancer research and control program authorized by the last session of Congress, were reviewed and approved by the National Advisory Cancer Council, a nongovernmental committee of cancer specialists. Among the projects approved and the sums granted are the following:

Yale University School of Medicine, $25,000.00. Improvement of cancer teaching.

Washington University at St. Louis, $10,800 00. Experiment in medical education and oncology.

Medical College of the State of South Carolina, $21,800.00. Establishment of cancer control clinic, teaching and research

Ohio State University College of Medicine, $24,800.00. Coordination of cancer teaching.

University of Chicago, $24,840.00. Development of research and teaching of cancer biology in a unit of oncology.

University of Tennessee, $24,035.40. Improvement and coordination of cancer teaching.

Tufts College, $24,820.00. Cancer control teaching.

Georgetown University, $24,500.00. Cancer teaching.

University of North Carolina, $3,400.00. Visual aids program for teaching pathology of neoplasms to medical students.

American *College of Surgeons, $30,340.00. Survey of cancer clinics* throughout the United States.

Tennessee Department of Public Health, $5,440.00. Epidemiologic and statistical research.

American Cancer Society, $36,600.00. Cooperative project for the production of diagnostic motion pictures.

Cornell University, $37,800.00. Establishment of a center for the study and instruction in the cytologic method for cancer diagnosis.

Maryland State Department of Health, $11,695.00. Evaluation of the cy*tologic test for cancer.*

University of Minnesota, $21,250.12. Establishment of a model cancer detection center.

Georgetown University, $9,000.00. Follow-up studies of benign and malignant tumors.

University of Louisville, $7,000.00. Follow-up and analysis of cancer cases treated at Louisville General Hospital over the last twenty years.

Michigan Department of Health, $1,800.00. Training of pathologists in the technic of the cytologic test for cancer.

State Department of Health of Kentucky. Cytologic test training project, $2,250.00. Operation of a mobile diagnostic and treatment clinic, $11,700.00.

University of Tennessee, $4,878.48. Survey of the cytologic test for cancer in the city hospital.

MISCELLANEOUS

SALE OF SURPLUS GOVERNMENT PROPERTY

The War Assets Administration is conducting sales of surplus government property announced by the following regional offices. Physicians who are veterans have certain priorities in the purchase of surplus government property.

Chicago.—Sale of drugs, medicine and cosmetics. Beginning October 24 priority-registered hospitals may buy throughout October 30; wholesale and retail drug outlets and certified physicians may buy starting November 3. The property for sale is located in building 3212 B, Great Lakes, Ill.

Seattle.—Sale of drugs, bandages, splints and heating pads. Bids open November 7 for commercial buyers. No priority rights, as this property was previously offered to priority claimants. Bids must be received at the War Assets Administration Customer Service Center, 1409 Second Avenue, Seattle, before 11 a. m. November 7.

St. Louis.—Sale of drugs, medical supplies and equipment to priority claimants and commercial buyers to December 17. Bids may be sent to any WAA Customer Service Center (of which there is at least one in every state and in some states many). A deposit of 10 per cent of the total offering price must accompany each offer, and on any order exceeding $100,000 the customer must add 2 per cent of the amount of excess to the 10 per cent deposit required on smaller sums.

Louisville.—Sale of drugs, chemicals, surgical instruments, sterilizers, autoclaves, laboratory lamps, hospital equipment and supplies, and culture mediums and solutions. Sale opens to priority claimants only starting October 27. This sale is said to include $10,000,000 worth of government property with 1,800 different items from which to select. The Customer Service Center in Louisville is at 410 West Jefferson Street, but information can be obtained from any other Customer Service Center in the country.

Medical News

(Physicians will confer a favor by sending for this department items of news of general interest: such as relate to society activities, new hospitals, education and public health. Programs should be received at least two weeks before the date of meeting.)

CALIFORNIA

Trichinosis and a Hamburger.—The first case of trichinosis in Los Angeles County in two years was recently reported by the Los Angeles County Health Department. County food and drug inspectors found that the infected person had eaten raw hamburger ground in the same machine used for grinding pork and sausage.

Symposium on Heart Disease.—The Heart Division of the San Francisco Tuberculosis Association will present a symposium on heart diseases October 29 to November 1 at the St. Francis Hotel at 2 p.m. The first afternoon's program, sponsored by the American Academy of Pediatrics, Northern California, will be devoted to heart disease in children. Speakers from this state and guests from other parts of the country will take part in the program.

Hospitals Merge to Form Medical Center.—The merger of Mount Sinai Hospital, Los Angeles, and the Los Angeles Sanatorium at Duarte has been completed to form the Mount Sinai-Duarte National Medical Center. Directors of the hospitals will serve as associate directors in the same capacities they held previously. The Los Angeles Sanatorium has provided free care for the tuberculous poor since 1913, while Mount Sinai Hospital has been active since 1920 in caring for those suffering from chronic ailments. The Mount Sinai Clinic has offered additional services to the Los Angeles needy. The center is dedicated to providing medical care for those suffering from chest diseases, cancer, heart disease and other major illnesses. The Medical Center will create facilities for postgraduate medical education, a nurses' training school, medical research and eventually a medical school under Jewish auspices. New buildings under construction at Duarte will accommodate more than 700 patients.

COLORADO

Annual Meeting of the State Society.—At the seventy-seventh annual session of the Colorado State Medical Society, September 17-20, the house of delegates adopted recommendations of its various committees, some of which follow:

1. The establishment of a statewide service for rehabilitation of civilians suffering physical handicaps, to provide for the nonmilitary victims care and rehabilitation equal to that now provided war veterans.
2. Revision and improvement of the whole field of neuropsychiatric care in the state.
3. Setting up a *non-tax-supported, community operated and controlled* child guidance center in Denver.
4. Approval of a six point program for the improvement of industrial health laws and services in the state with special consideration of the smaller, more widely dispersed industrial plants.
5. Approval of a seven point program for the improvement of rural health in the state with emphasis on expansion of the coverage of rural residents under Colorado Medical Service, Inc., the society-sponsored prepayment medical care plan.
6. Assumption of leadership toward establishment of scientifically planned health education in all levels of the state's educational system.
9. Expansion of Colorado Medical Service, Inc., from its present limited *surgical care plan operations to include nonsurgical conditions.*

The house of delegates created a Board of Supervisors, which will serve both in the general capacity of a "grand jury" and as a continuing study group to issue periodic advice to the members of the medical profession on matters of ethics and public conduct. It is empowered to receive complaints from physician and layman alike and, when justified, to prosecute charges against any erring physician before a local board of censors, the state Board of Councilors, the official Colorado State Board of Medical Examiners or any court. A temporary board of supervisors of twelve members, no two from the same component society, was nominated and elected to serve until a permanent board can take over under a constitutional amendment which will require one year to become effective. It was provided that no member of the board may participate in proceedings which affect a member of his own component society. The society voted also to join with the Colorado State Dental Association in cosponsorship of the proposal for establishing an approved school of dentistry in Colorado. There is no dental school in the Rocky Mountain region. The house of delegates directed that a new special committee be charged with the development of standards with which governmental and private agencies dealing with health and medical care problems must comply in order to obtain or maintain support of the medical profession. At this annual session the society awarded two special certificates, one to Dr. Florence R. Sabin, Denver, "for her life-long devotion to medical research and public health"; the other to Dr. Ella A. Mead, Greeley, in recognition of her more than twenty years of service as a member, and many times chairman, of the society's Board of Councilors. The following officers of the Colorado State Medical Society were installed: Drs. John S. Bouslog, Denver, president; Casper F. Hegner, Denver, president-elect, and George C. Shivers, Colorado Springs, treasurer.

CONNECTICUT

Yale Reorganizes Psychiatry Department.—Complete reorganization of the department of psychiatry at Yale University School of Medicine, New Haven, with emphasis on the newest methods of treating mental illness, expanded instruction of medical students and residency training in cooperation with the Veterans Administration was announced October 2. Personnel changes include the appointment of Drs. Frederick C. Fedlich, New Haven, executive officer of the department; Burness E. Moore, New Haven, physician-in-charge of the psychiatric inpatient clinic, and Richard J. Newman, Maryland, N. Y., physician-in-charge of the outpatient clinic. Dr. Lawrence S. Kubie, New York, has been appointed clinical professor of psychiatry; *Dr. Robert P. Knight, Stockbridge, Mass., clinical* professor, and Dr. Paul I. Yakovlev, Middletown, as associate clinical professor. The psychiatric inpatient clinic in the Yale Institute of Human Relations Building is in process of being completely renovated. Increasing emphasis will be placed in the clinic on the psychoneuroses and on psychosomatic disorders. Patients will be cared for jointly by the psychiatric staff and internists of the staff of the Yale School of Medicine and the New Haven Hospital. An individualized treatment program has been set up with major emphasis on psychotherapy, in which resident physicians will be carefully supervised. Two occupational therapeutists will be added to the staff. Yale Divinity School students will serve as male attendants in the wards as a part of their teaching program. Increasing emphasis will be placed on instruction of medical students in psychiatry. A new approach at Yale is the plan to help students to deal more adequately with psychiatric problems in general practice or in the specialties other than psychiatry. A new residency training program in neuropsychiatry, which will be under the Dean's Committee of the Veterans Administration, was started at Yale on October 1. A Veterans Administration contract clinic is presently operating in the psychiatric outpatient clinic. A Connecticut postgraduate seminar in neuropsychiatry has been organized and will be sponsored by the Joint State Hospital Committee and Yale. The psychiatry department will cooperate closely with the Yale Divinity School, Law School, Institute of Human Relations, the department of psychology, department of public health and the division of psychiatry of the Yale Department of University Health under Dr. Clements C. Fry.

FLORIDA

Four District Meetings.—The Florida Medical Association has arranged four district meetings for its membership with programs beginning at 2:30 p.m. and ending with dinner.

Northwest Medical District, October 27, St. Andrews Bay Yacht Club, Panama City.
Southwest Medical District, October 29, Yacht and Country Club, Lakeland.
Southeast Medical District, October 30, *New Fort Pierce Hotel, Fort* Pierce.
Northeast Medical District, November 1, St. Augustine Country Club, St. Augustine.

Scientific assemblies and general sessions are included in the programs.

Cancer Seminar at Jacksonville.—A three day seminar on cancer will be held in Jacksonville November 12-14. There will be no registration fee. Funds for the project have been provided by the Florida Division of the American Cancer Society and the Florida State Board of Health. The Tumor Clinic of the Duval County Hospital initiated the project, and the physicians of Duval County will be the hosts. Invitations have been issued to all members of medical societies of the Southeastern states. Speakers will be:

Emil Novak, Baltimore, Tumors of the Female Genital Tract.
Samuel F. Marshall, Boston, Tumors of the Gastrointestinal Tract.
Archie L. Dean, New York, Tumors of the Genitourinary Tract.
Everett D. Sugarbaker, Jefferson City, Mo., Tumors of the Breast.
George T. Pack, New York, Mixed Tumors.
James E. Scarborough, Atlanta, Ga., Tumors of the Head and Neck.
Herbert D. Adams, Boston, *Tumors of the* Chest.
Roscoe R. Spencer, Bethesda, Md., Cancer Research.
Everett L. Bishop, Atlanta, Ga., Tumor Pathology.

ILLINOIS

Graduate Conference at Rockford.—The Illinois State Medical Society has arranged a postgraduate conference for the First Councilor District at the Hotel Faust, Rockford, November 5, beginning at 1:30 p.m. and extending into the evening. Seven Chicago physicians will speak on coronary disease, hypertension, congenital heart deformity, kidney diseases, fracture problems and peptic ulcer.

Annual Conference on Exceptional Children.—The State Commission for Handicapped Children will sponsor the fourth annual Governor's Conference on Exceptional Children, to be held in Springfield, October 24, at the Leland Hotel. The conference will give an opportunity for first hand observation of methods in educational rehabilitation of handicapped children. Any one interested is invited to attend Speakers on the program include: Dr. Roland R. Cross, director, Illinois Department of Public Health, Springfield; Morton A. Seidenfeld, Ph.D., director of psychologic services, National Foundation for Infantile Paralysis, New York; Dr. Francis N. Brill, orthopedic surgeon of Springfield, and Howard F M. Miller, executive director, Illinois Commission for Handicapped Children, Chicago.

Chicago

Narcotic Violation.—Dr. Chester A. Price, 6345 University Avenue, Chicago, pleaded nolo contendere to an indictment charging violation of the Federal Narcotic Law and on September 4 was sentenced to a term of one year and one day.

Course in Electrocardiographic Interpretation.—A course in electrocardiographic interpretation for graduate physicians will be given at the Michael Reese Hospital Postgraduate School by Dr. Louis N. Katz, director of cardiovascular research. The class will meet each Wednesday from 7 to 9 p.m. for twelve weeks, beginning Feb. 17, 1948. Information may be obtained from the Office of the Dean, Michael Reese Hospital Postgraduate School.

University Course in Allergy.—A twelve month graduate course for clinical training and research in allergy is being offered by the University of Illinois allergy unit, a joint organization of the colleges of medicine and pharmacy, during the 1947-1948 school year. The course, open to six physicians, is designed to train specialists in allergy to help alleviate the shortage of allergists in the country. Though primarily clinical in scope, the course will include instruction in basic subjects related to allergy. The training and research program will be correlated with the university's allergy clinic. Registration was conducted October 1.

INDIANA

Honor Peru's Fifty-Year Physicians.—The Eleventh District Medical Association at a banquet September 17 in Peru honored Drs. Frank M. Lynn, David C. Ridenour and John E. Yarling, all of Peru, who have been in practice more than fifty years. Dr. Edgar F. Kiser, Indianapolis, was the principal speaker.

Testimonial Dinner to Dr. Sensenich.—A testimonial dinner in honor of Dr. Roscoe L. Sensenich, President-Elect of the American Medical Association, was held October 8 at the Indiana Club, South Bend, under the auspices of the St. Joseph County Medical Society, of which he is a member. Dr. Harold D. Pyle, president, presided. The after dinner address was given by Dr. Morris Fishbein, Chicago, Editor of THE JOURNAL, on medical statesmanship. Dr. Robert B. Sanderson, South Bend, presented a scroll to Dr. Sensenich. Other speakers were Dr. Floyd H. Romberger, president, Indiana State Medical Association, and Drs. Ernest R. Irons, Chicago, Secretary, and Elmer L. Henderson, Louisville, Ky., Chairman, Board of Trustees, American Medical Association.

Division of Venereal Disease Control.—Dr. Carl C. Kuehn, Indianapolis, formerly with the U. S. Public Health Service, has been placed in charge of venereal disease control activities of the state board of health, succeeding Dr George W. Bowman, Indianapolis, who is being loaned to the Indianapolis City Board of Health to help with venereal disease control and continue his work at the rapid treatment center. A graduate of Indiana University School of Medicine, Bloomington-Indianapolis, 1941, Dr. Kuehn attended the school of public health at the University of Michigan, Ann Arbor, and received his master's degree in public health last spring. Dr. C. Merle Bundy, Indianapolis, who for the last year has been acting director of the division of tuberculosis control on loan from the U. S. Public Health Service, has decided to resign from the Service and remain in the state. He is a graduate of the Indiana University School of Medicine, 1942.

KENTUCKY

State Medical Election and Awards.—At the annual meeting of the Kentucky State Medical Association September 29-October 2, Dr. J. Garland Sherrill, Louisville, received the association's Distinguished Service Medal for pioneering in the use of spinal anesthesia. Dr. J. Duffy Hancock, a member of the surgical faculty of the University of Louisville School of Medicine, Louisville, since 1923, from which school he graduated in 1921, received the E. M. Howard Medal for outstanding services as a physician and surgeon. The association installed Dr. Guy Aud, Louisville, as president and chose Dr. Charles A. Vance, Lexington, president-elect.

MICHIGAN

Typhoid at Saginaw Checked.—Typhoid fever, which 12 persons of Saginaw contracted in September, has been traced to a contaminated surface well, according to Dr. Frederick S. Leeder, Lansing, director of the state health department's bureau of epidemiology. The well apparently was contaminated by the discharge from a septic tank, and the carrier is being sought.

NEBRASKA

Creighton University Appointments.—Among the recent appointments to the faculty of the Creighton University School of Medicine, Omaha, are: assistant professor of bacteriology, James M. Beebe, Ph.D., Amherst, Mass.; assistant professors of physiology and pharmacology, Harold C. Struck, Ph.D., Chicago, and John Ferguson, Ph.D., Edmonton, Alberta, Canada; instructor in pathology, Dr. F. J. Campos, El Paso, Texas; assistants in surgery, Drs. Robert Fitzgibbons, William N. Hardman, both of Rochester, Minn., in charge of anesthesiology, and Harry H. McCarthy, Rochester, Minn.; assistant in medicine, Dr. John D. Hartigan, Rochester, Minn.; acting assistants in medicine, Drs. Richard J. Fangman and William O. Griffith, Council Bluffs, Iowa.

NEW YORK

Graduate Instruction for County Societies.—The Medical Society of the State of New York and the New York State Department of Health have arranged postgraduate instruction for the following county medical societies:

Clinton County, December 18 at 8 p. m. in the Champlain Valley Hospital Nurses Home, Plattsburg, on arthritis.

Jefferson County, November 13 at 8:30 p. m. at the Woodruff Hotel, Watertown, on medical aspects of the atomic bomb.

Appoint Director of Public Health Education.—Dr. Granville W. Larimore, New York, has been appointed director of the Office of Public Health Education, State Health Department, succeeding Mr. Bert R. Rickards, who served for thirty years (THE JOURNAL, Feb. 8, 1947, page 413). Dr. Larimore comes to the department from the American Cancer Society, where he had been educational director. He received his M.D. degree from Rush Medical College of the University of Chicago in 1936 and a Master of Public Health from Harvard University in 1942. During the War he served as chief of the army's health education branch, venereal disease control division.

New York City

Lectures for Laymen.—The New York Academy of Medicine will inaugurate the thirteenth series of its Lectures to the Laity with the Linsly R. Williams Memorial Lecture to be delivered October 30 at 8:30 p.m. by Lewis L. Strauss, New York, member of the U. S. Atomic Energy Commission, on "The Atom in Civil Life." On November 1 Dr. George R. Hargreaves, London, will speak on "Psychology of Leadership in War and Peace." The third lecture will be the ninety-eighth anniversary discourse of the New York Academy of Medicine, to be given by Sir Raphael Cilento, director of social activities, United Nations, Lake Success, N. Y., on "Food and Civilization."

Hospital Physicians Added to University Staff.—Eleven staff members of hospitals have received academic appointments at Columbia University College of Physicians and Surgeons as a result of the university's recently announced plan of affiliation with St. Luke's Hospital and Mary Imogene Bassett Hospital in Cooperstown (THE JOURNAL, Aug. 23, p. 1496). Dr. William F. MacFee, director of surgery at St. Luke's, was named clinical professor of surgery. Assistant professors of surgery are Drs. Benjamin Shore Jr. and Paul C. Morton; assistant clinical professors of medicine, Drs. John J. Keating, Albert C. Herring and Waldo B. Farnum. Staff members of the Goldwater Memorial Hospital, Welfare Island, who received appointments are Drs. Margaret Bevans and Robert W. Berliner. At the Mary Imogene Bassett Hospital Dr. James Bordley III was appointed associate clinical professor of medicine and Dr. Monroe A. McIver, associate clinical professor of surgery.

Cancer Detection Center Opened.—The first Cancer Prevention and Detection Center to be operated by the city health department has been opened at the Kips Bay-Yorkville Health Center, 411 East Sixty-Ninth Street. The center is a cooperative project sponsored by the city health department, the New York City Cancer Committee, Cornell University Medical College and the Strang Cancer Prevention Clinic of Memorial Hospital for the Treatment of Cancer and Allied Diseases. Operation of this center, planned by the health department as the first of several, will determine the most effective way to administer such programs. The New York City Cancer Committee will supply funds for professional personnel and special services for the first year of operation. The objective is to determine those persons who show symptoms for which diagnostic investigation is indicated. Treatment will not be given, and the detection service will be free. The center will be open to presumably well adults regardless of age. However, chief attention will be directed to persons over 40 years of age who are referred either by their physician or some medical service, or who may come without referral. Patients giving indications of any condition requiring medical attention will be referred to their physicians or to an appropriate clinic. Dr. Emerson Day of Cornell University Medical College will direct the cancer center. The health department is furnishing space, nursing and secretarial service and laboratory, dental and x-ray facilities. Staff members of the New York and Memorial hospitals will serve as consultants on special cases. An advisory committee of the sponsors will determine the general policies governing the clinic and select the medical personnel.

OHIO

Research on Radioactive Substances.—Under a $100,000 grant from the U. S. Atomic Energy Commission, Western Reserve University School of Medicine, Cleveland, will conduct research on the effects of radioactive substances and atomic energy on the body and on living cells. Dr. Hymer L. Friedell, professor of radiology, will direct the project and Dr. Arnold D. Welch, head, department of pharmacology, and Harland G. Wood, Ph.D., head, department of biochemistry, will be consultants. Paul A. Mattis, Sc.D., former professor of pharmacology, University of Florida School of Pharmacy, now at the Western Reserve School of Pharmacy, will direct the pharmacologic division of the project. Dr. Paul S. Lavik, assistant professor of biochemistry in the school of medicine, will study the effects of radioactive elements on enzymes and will supervise the work of the biochemical division. This research will be related to that conducted in several other institutions by the Atomic Energy Commission.

OREGON

Narcotic Violation.—Dr. Philip L. Newmyer, Portland, who was arrested May 9 and freed on $2,500 bond, was fined $5,000 in federal court when found guilty on six counts charging him with violating the Federal Narcotics Act by the sale of morphine tablets not in the course of his professional practice.

First Woman Elected President.—At the annual session of the Oregon State Medical Society in Portland, September 4-6, Dr. James C. Hayes, Medford, was installed as president. Dr. Leslie S. Kent, Eugene, was made president-elect; Dr. Werner E. Zeller, Portland, secretary, and Dr. Roger H. Keane, Portland, treasurer. Dr. Kent is the first woman to be chosen to head a state medical association. Dr. Kent, whose father and late husband were physicians, received her M.D. degree from Lincoln Medical College, Lincoln, 1917. In 1923 she began practice in Eugene. She is a former president of the Lane County Medical Society.

PENNSYLVANIA

State Medical Election.—At the annual session of the Medical Society of the State of Pennsylvania, September 15-18, Dr. Elmer Hess, Erie, was installed as president. Dr. Gibson C. Engel, Philadelphia, was chosen president-elect and Dr. Walter F. Donaldson, Pittsburgh, was reelected secretary-treasurer for the twenty-ninth consecutive year.

A Series of Graduate Courses.—The medical society of the state of Pennsylvania in cooperation with the medical schools of the state has arranged a series of graduate refresher courses to be held from October through May for general practitioners. Physicians may select one of the following centers: Allentown, Harriburg, Johnstown, Oil City, Wilkes-Barre or Williamsport. Each day of instruction will consist of eight hours. Emphasis will be placed on physiologic and pharmacologic points of view. Subjects to be covered are febrile diseases and endocrinology, cardiovascular diseases, neuropsychiatry, skeletal and muscular diseases, hematology and metabolic disorders, skin diseases and nutrition, urology, gynecology and obstetrics, respiratory diseases and anesthesiology, gastroenterology and modern therapy. The schedule is so arranged that a registrant who is unable to attend a particular session at his own center will be able to attend an identical session by traveling to a neighboring center on another date. The registration fee for members of the state society is $25; for nonmembers, $50. Information may be obtained from the Committee on Graduate Education, 230 State Street, Harrisburg.

WEST VIRGINIA

Pediatric Consultant.—Dr. Henrietta L. Marquis, Charleston, has been appointed as part time pediatric consultant to the division of maternal and child health. Before moving to Charleston in 1946, Dr. Marquis practiced pediatrics at Beckley. She has participated in the child health program of the state health department since 1935 and has served as a clinician at the Well-Child Conference in Beckley.

Hospital Advisory Board.—A seven member hospital-licensing advisory board has been appointed by the governor under the provisions of the hospital-licensing act passed by the legislature this year. The members will serve as consultants to the commissioner of health in issuing licenses to hospitals, sanatoriums, nursing homes and related institutions. The board is composed of John S. Alfriend, Charles Town; Charles Warner and C. R. Adams, Charleston; Dr. Hu C. Myers, Philippi; J. S. Turk, Wheeling; Sister M. Carola, Huntington, and James L. Foster, Bluefield.

WISCONSIN

Dr. Hirschboeck Appointed Dean.—Dr. John S. Hirschboeck, a member of the faculty of Marquette University School of Medicine, Milwaukee, since 1939, was appointed dean of the school September 28, to succeed the late Dr. Eben J. Cary. He was graduated from Marquette University School of Medicine in 1937, and in 1941 he received a degree of master of science, specializing in hematology. He served in the Navy from Dec. 14, 1941 to 1945.

Walter Zeit to Head of Department of Anatomy.—Walter Zeit, Ph.D., who has been an associate professor of anatomy at Marquette University School of Medicine, Milwaukee, since 1943, has been appointed director of the department to succeed the late Dr. Eben J. Carey. Dr. Zeit received his Ph.D. degree from Marquette University in 1939 and has been on the staff of the School of Medicine since 1921, having been an assistant in anatomy as an undergraduate.

GENERAL

Diploma Lost.—The diploma of Dr. Collins Fremont Hall, who graduated from Duke University School of Medicine, Durham, N. C., on June 6, 1938, has been lost. A duplicate is being issued by Duke to Dr. Hall.

International College Dedicates Home.—The United States Chapter of the International College of Surgeons dedicated its new home office at 1516 Lake Shore Drive, Chicago, at a program October 2. Dr. Raymond W. McNealy, Chicago, was general chairman of the program, and Dr. Herbert Acuff, Knoxville, Tenn., presided.

Central Society for Clinical Research.—The Society for Clinical Research will hold its twentieth annual meeting October 31-November 1 at the Drake Hotel, Chicago, under the presidency of Dr. Carl V. Moore, St. Louis. Numerous short papers will be presented by speakers from various sections of the country. There will not be exhibits or a social program.

Dr. Eusterman Receives Friedenwald Medal.—Dr. George B. Eusterman, Mayo Clinic, Rochester, Minn., was the recipient of the Friedenwald Medal given at the annual meeting of the American Gastro-Enterological Association in Atlantic City, N. J., in June for his outstanding work in gastroenterology. The July issue of *Gastroenterology* was dedicated to Dr. Eusterman.

Dr. Perkins Named Director of National Tuberculosis Association.—Dr. James E. Perkins, Albany, deputy commissioner, New York State Health Department, on Jan. 1, 1948 will succeed Dr. Kendall Emerson, New York, retired, as managing director of the National Tuberculosis Association. Dr. Perkins has been connected with the New York State Department of Health since 1934, when he joined the staff as an epidemiologist. He was last year appointed deputy commissioner. Dr. Emerson, managing director since 1928, has agreed to remain a consultant to the association.

Military Surgeons Meeting.—The Association of Military Surgeons of the United States will hold its annual convention at the Hotel Statler, Boston, November 13-15, under the presidency of Dr. Warren F. Draper, Washington. The program is made up of lectures on atomic energy, aviation medicine, preventive and environmental medicine; current personnel problems, psychiatry, research and development, dentistry and veterinary medicine, medicine and surgery, and panel discussions on the Army Nurse Corps, aviation medicine, dentistry and the Medical Service and Sanitary Corps.

Annual Meeting of Clinical Pathologists.—The annual meeting of the American Society of Clinical Pathologists will be held at the Drake Hotel, Chicago, October 27-30 with demonstrations at the University of Illinois College of Medicine and its Research and Educational Hospitals, Mt. Sinai Hospital and Hektoen Institute. The program includes a symposium on cardiolipin antigen and a seminar on Thursday on diseases of the kidney. There will be technical and scientific exhibits. At the banquet October 29 Dr. Edward L. Bortz, Philadelphia, President, American Medical Association, will speak on "Medicine's New Frontiers."

Prevalence of Poliomyelitis.—Reports of cases of poliomyelitis for the periods indicated have been received from the division of public health methods, U. S. Public Health Service:

† Figures changed by corrected reports.

Survey of Food and Nutrition Research.—A national survey of activities in the field of food and nutrition research is being undertaken by the Food and Nutrition Board of the National Research Council with the support of the Quartermaster Food and Container Institute of the armed forces. Leaders in the field have expressed a need for a central register of food and nutrition research to facilitate the coordination of peacetime research in relation to national security and public welfare. The register will serve as a basis for rapid mobilization of food research resources in event of national emergency. The survey will cover the chemical, physiologic, microbiologic, technologic, psychologic and basic economic studies of nutrition research. Correlation of such studies with regard to health, acceptability, stability, utility and economy of food will be made. Subject listings of research and progress pertaining to foods and nutrition are being obtained from directors of research in industry, universities, government and other agencies, foundations, public trusts and industry. In addition, a roster of personnel engaged in research is being developed in collaboration with the Office of Scientific Research of the Research Council. Charles G. King, Ph.D., Scarsdale, N. Y., scientific director of the Nutrition Foundation, is chairman of the committee on survey of food and nutrition research, which will supervise the project and make reports. Information may be obtained from the office of the Food and Nutrition Board of the National Research Council, 2101 Constitution Avenue, Washington, D. C.

AUSTRALIA

Flying Doctor Service.—From eight bases throughout Australia the flying doctor service brings medical aid to families and sheep ranchers in Australia's "outback." Each base, according to the Associated Press, has a physician, pilot and radio operator, and a two way radio and twin engined airplane fitted out as an ambulance. People on isolated farms contact the base with a "pedal wireless," which can be installed in homes for $275. Medical advice for mild illnesses is given from the base by radio with instructions for the use of a medical kit with which every home is equipped. If a patient needs hospital attention he is flown back to the base in the aerial ambulance. The service is maintained by government subsidy, private donations and a voluntary contribution scheme by which settlers pay a yearly subscription. Nonsubscribers receive free medical advice by radio but are expected to pay for a doctor's call. Charges are based on the average carrying capacity of the property and range from $16 for property with three thousand sheep to $65 for property with seventeen thousand sheep. Dr. John Flynn, superintendent of the Presbyterian Inland Mission, began the service twenty-six years ago with one base at Cloncurry in North-West Queensland.

EGYPT

Cholera in Egypt.—According to the Associated Press, the death toll in the three week cholera epidemic in Egypt had reached 2,128 by October 19. On the preceding day the health ministry listed 247 deaths in the twenty-four hours ending at 8 a. m. A specially equipped plane of the United States air force arrived in Cairo October 19 from Frankfort, Germany, with 100,000 gallons of DDT spraying mixture to combat flies spreading the disease. It is expected that the plane will be used to reach distant areas while smaller aircraft continue to spray Cairo and the nearby region.

Marriages

Truman G. Schnabel Jr., Philadelphia, to Miss Mary Florence Hyatt of Washington, Ind., in New York, September 13.

George Louis Armbrecht to Miss Eleanor Lincoln Flint, both of Wheeling, W. Va., September 30.

Richard Lord I[illegible]ey, New York, to Miss Mary Catesby Jones of Petersham, Mass., September 6.

Kenneth Shiler Shepard, Washington, D. C., to Miss Helen Reis of Evanston, Ill., recently.

John M. Keller, Philadelphia, to Miss Ruth Clare Stranford of Ashland, N. J., September 26.

Frances A. Swan, Livonia, N. Y., to Mr. Walter H.. Lieneck of Brooklyn, August 16.

John Horton Doane Jr., Sayre, Pa., to Miss Hilda Mann Hogg of Towanda, August 23.

Anson G. Hurley to Miss Betty Pheneger, both of Muncie, Ind., September 6.

Deaths

Barney James Hein ⊕ Toledo, Ohio; born in Toledo on April 23, 1889; Toledo Medical College, 1912; specialist certified by the American Board of Orthopaedic Surgery; member of the House of Delegates of the American Medical Association since 1939; member of the Clinical Orthopaedic Society and the American Academy of Orthopaedic Surgeons; fellow of the American College of Surgeons; president of the Ohio State Medical Association, 1938-1939, and for three terms served as councilor of the Fourth District, in which position he was active on various committees; chairman of the committee on public relations and economics since 1940; a member and formerly chairman of the committee on industrial health and workmen's compensation; member of the board of directors of Ohio Medical Indemnity, Inc., the association's prepayment medical care plan; president of the Academy of Medicine of Toledo and Lucas County in 1930; during World War I served overseas in charge of the orthopedic department of Evacuation Hospital number 5 and saw active service in Aisne-Marne, Oise-Aisne, St. Mihiel, Meuse, Argonne and Ypres-Lys engagements; following duty at Orthopedic Base Hospitals number 9 and 11 was discharged as a captain in March 1919; director of the orthopedic staff at St. Vincent's Hospital and member of the orthopedic staffs at Toledo, Flower, Riverside and Lucas County General hospitals; served as trustee for the Toledo Newsboy's Association (later the Boys' Club of Toledo), the Toledo Hospitalization Association, Toledo Society for Crippled Children, Toledo Chamber of Commerce and the Toledo Medical College Fund of Toledo University; served on the advisory board of the University of Toledo's athletic department; charter member and past president of the Lion's Club of Toledo; died August 17, aged 58.

James A. Abney, Brownwood, Texas; Galveston Medical College, 1871; Confederate veteran; died July 29, aged 100, of senility.

John Pelham Bates, Greenwood, Miss.; Vanderbilt University School of Medicine, Nashville, Tenn., 1896; on the staff of the Greenwood Leflore Hospital, where he died August 8, aged 79, of myocarditis.

Franklin Carlisle Bivings, Atlanta, Ga.; University of Illinois College of Medicine, Chicago, 1916; served during World War I; on the staff of St. Joseph's Infirmary, where he died August 7, aged 68, of coronary heart disease.

Frank Brostrom ⊕ New Orleans; Jefferson Medical College of Philadelphia, 1923; affiliated with Touro Infirmary and the New Orleans Hospital and Dispensary for Women and Children; died July 31, aged 53, of coronary thrombosis.

Henry M. Brown, Roswell, N. M.; Chicago Medical College, 1892; died in Colorado Springs July 31, aged 80, of coronary thrombosis.

Henry Campbell, Graham, Mo.; Kentucky University Medical Department, Louisville, 1903; died in St. Francis Hospital, Maryville, July 29, aged 67, of cerebral hemorrhage.

Lewis Richard Carr, Wayne, Ohio; Ohio State University College of Medicine, Columbus, 1916; past president of the Academy of Medicine of Toledo and Lucas County; served during World War I; formerly on the staff of the Flower Hospital in Toledo; member of the Clinical Orthopaedic Society and the American Academy of Orthopaedic Surgeons; died July 31, aged 56, of cerebral hemorrhage.

Frank Elijah Chapman, Montgomery, Ala.: Louisiana State University School of Medicine, New Orleans, 1937; member of the American Medical Association; formerly affiliated with the Pines Sanatorium in Shreveport, La.; served with the division of tuberculosis control of the state department of public health; died in Grove Hill August 19, aged 34, of tuberculosis.

William Stewart Chapman, Jackson, Ala.; Emory University School of Medicine, Atlanta, Ga., 1924; member of the American Medical Association; past president of the Clarke County Medical Society; councilor of the Medical Association of the State of Alabama; died July 22, aged 50, of coronary occlusion.

George William Cline, Muncie, Ind.; Indiana University School of Medicine, Indianapolis, 1941; member of the American Medical Association; interned at the Eloise Hospital and Infirmary in Eloise, Mich.; served a residency at the Logansport State Hospital in Logansport, Ind.; died in the Union City Hospital in Union City, July 6, aged 33, of cerebral hemorrhage.

Manning E. Cohn, Cleveland Heights, Ohio; Ohio State University College of Medicine, Columbus, 1933; member of the American Medical Association; served during World War II; died in the Mount Sinai Hospital in Cleveland July 11, aged 39, of coronary thrombosis.

James Joseph Collins, Woodbridge, N. J.; Long Island College Hospital, Brooklyn, 1907; died June 19, aged 70, of hypertension, diabetes mellitus and a fractured femur received in a fall.

Francis Joseph S. Conlan ⊕ San Francisco; Rush Medical College, Chicago, 1899; member of the Pacific Coast Oto-Ophthalmological Society; fellow of the American College of Surgeons; on the staff of St. Mary's Hospital, where he died July 17, aged 73, of coronary heart disease.

Paul James Connor ⊕ Denver; University of Texas School of Medicine, Galveston, 1912; specialist certified by the American Board of Internal Medicine; fellow of the American College of Physicians; past president of the state board of health; served during World War I and as president of the staff of the Presbyterian Hospital; affiliated with St. Luke's Hospital, where he died July 26, aged 60, of heart disease.

Charles Eli Cottingham, Indianapolis; Medical College of Indiana, Indianapolis, 1895; member of the American Medical Association; served on the faculty of the Indiana University School of Medicine and on the staffs of the Richmond (Ind.) State Hospital, James Whitcomb Riley, City, St. Vincent's and Methodist hospitals; died July 23, aged 78, of coronary thrombosis.

William Allen Cracraft Jr., Wheeling, W. Va.; University of Virginia Department of Medicine, Charlottesville, 1901; member of the American Medical Association; served in France during World War I; on the staff of the Ohio Valley General Hospital, where he died July 10, aged 69, of hypertensive heart disease.

Herbert William Emerson, Ann Arbor, Mich.; University of Michigan Medical School, Ann Arbor, 1915; member of the American Medical Association; served on the faculty of his alma mater; died in the Hamilton General Hospital, Hamilton, Ontario, Canada, June 21, aged 66, of cerebral hemorrhage.

Charles Fox Gardiner, Colorado Springs, Colo.; Bellevue Hospital Medical College, New York, 1882; member of the American Medical Association and the American Clinical and Climatological Association; affiliated with the Beth-El Hospital; author of "Doctor at Timberline"; died July 31, aged 89, of myocarditis.

Harold Eugene Gibson ⊕ Kenton, Ohio; Eclectic Medical College, Cincinnati, 1915; served in France during World War I; past president of the Hardin County Medical Society; died suddenly, July 2, aged 54, of coronary occlusion.

Florence Gilman ⊕ Poughkeepsie, N. Y.; Tufts College Medical School, Boston, 1902; member of the Massachusetts Medical Society; at various times affiliated with Smith College, Northampton, Mass., Vassar College, Poughkeepsie, and Radcliffe College, Cambridge, Mass.; died in Meredith, N. H., July 31, aged 69, of coronary occlusion.

Ralph Warren Goss, Litchfield, Me.; Medical School of Maine, Portland, 1904; served as a member of the school board; died July 16, aged 68, of mesenteric thrombosis.

Henry Matthew Grady, Dedham, Mass.; Harvard Medical School, Boston, 1905; member of the American Medical Association; for many years physician for the welfare board; died July 30, aged 72, of cirrhosis of the liver.

James Graybeal, Chicago; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1907; member of the American Medical Association; formerly on the staff of the Englewood Hospital; died July 23, aged 73, of cerebral thrombosis and carcinoma of the prostate.

Luther Hays, Cullman, Ala.; Chattanooga (Tenn.) Medical College, 1900; also a graduate in pharmacy; member of the American Medical Association; veteran of the Spanish-American War; on the staff of Cullman Hospital; died July 7, aged 76, of carcinoma of the colon.

Robert Reeves Hays ⊕ Akron, Ohio; Jefferson Medical College of Philadelphia, 1922; specialist certified by the American Board of Psychiatry and Neurology; member of the American Psychiatric Association; at one time affiliated with the Pennhurst State Hospital in Pennhurst, Pa., Blair County Hospital for Mental Diseases in Holidaysburg, Pa., and the Danville (Pa.) State Hospital; served on the staff of St. Thomas Hospital; died in Cleveland August 21, aged 48, of coronary occlusion.

Thomas Francis Hennessey ⊕ Swampscott, Mass.; Tufts College Medical School, Boston, 1911; at one time practiced in Lynn, where he was for many years affiliated with the Lynn Isolation and Union hospitals; examiner of the draft during World War I; died July 21, aged 60, of coronary thrombosis.

Paul Stanley Hill, Saco, Maine; George Washington University School of Medicine, Washington, D. C., 1906; member of the American Medical Association, consultant at the Webber Hospital and co-owner of the Trull Hospital in Biddeford; died at his summer home in Biddeford Pool, July 26, aged 66, of coronary thrombosis.

Harry Conrad Himmelman, Chicago; Chicago College of Medicine and Surgery, 1912; on the staff of the Lutheran Deaconess Hospital, where he died July 20, aged 61, of coronary thrombosis.

Farish Clay Holden, Atlanta, Ga.; University of Georgia School of Medicine, Augusta, 1928; member of the American Medical Association; served as a member of the state board of medical examiners; medical consultant for the Veterans Administration; first lieutenant, medical reserve corps, U. S. Army, not on active duty; on the staffs of the Crawford W. Long and the Georgia Baptist hospitals; died in the Veterans Administration Hospital July 15, aged 47, of circulatory failure and chronic cholecystitis.

Stanley Hall Holland ⊕ McKeesport, Pa.; College of Physicians and Surgeons, Baltimore, 1914; president of the McKeesport Academy of Medicine; affiliated with the staff of the McKeesport Hospital, where he died July 22, aged 59, of coronary occlusion.

Alf Justin Holm ⊕ Chicago; Jefferson Medical College of Philadelphia, 1924; specialist certified by the American Board of Urology; fellow of the American College of Surgeons; served during World War II; clinical instructor in urology, department of surgery, University of Illinois College of Medicine; affiliated with the Alexian Brothers Hospital and the Ravenswood Hospital, where he died July 31, aged 49, of coronary thrombosis.

Lewis Wade Hood, Biloxi, Miss.; Mississippi Medical College, Meriden, 1911; past president of the school board; also a druggist; died July 24, aged 63, of heart disease.

Claude Gibson Hooten, Lynchburg, Va.; Bennett Medical College, Chicago, 1915; member of the American Medical Association; served during World War I; for many years medical examiner for the Norfolk and Western Railway; died in the Virginia Baptist Hospital July 25, aged 56, of heart disease.

Edward T. Hornback ⊕ Hannibal, Mo.; Missouri Medical College, St. Louis, 1891; specialist certified by the American Board of Ophthalmology; on the staffs of St. Elizabeth's Hospital and the Levering Hospital, where he died July 15, aged 83, of coronary thrombosis.

Edmund Newell Huff ⊕ South Pasadena, Calif.; Hahnemann Medical College and Hospital of Philadelphia, 1900; past president of the Bergen County (N. J.) Medical Society; at one time practiced in Englewood, N. J., where he was affiliated with the Englewood Hospital; at one time on the staff of the Holy Name Hospital at Teaneck, N. J.; on the staff of the Huntington Memorial Hospital in Pasadena; died July 3, aged 68, of aortic aneurysm and chronic hypertension.

Charles Henry Ingram, Fresno, Calif.; Cooper Medical College, San Francisco, 1903; member of the American Medical Association; on the staffs of St. Agnes Hospital and the Fresno Community Hospital, where he died July 28, aged 72, of cerebral thrombosis and cerebral hemorrhage.

Henry Janoff ⊕ Trenton, N. J.; Temple University School of Medicine, Philadelphia, 1934; affiliated with St. Francis Hospital; died in the F. W. Donnelly Memorial Hospital July 11, aged 39, of pulmonary tuberculosis.

Francis Arthur Jones ⊕ Lansing, Mich.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1903; fellow of the American College of Surgeons; on the staffs of Sparrow Hospital and St. Lawrence Hospital, where he died July 5, aged 73, of cerebral hemorrhage.

Henry Nathan Kehres ⊕ Bryn Mawr, Pa.; Jefferson Medical College of Philadelphia, 1932; served overseas during World War I; on the staff of Bryn Mawr Hospital, where he died July 17, aged 49, of coronary occlusion.

John Leo Kelliher, Detroit; Chicago College of Medicine and Surgery, 1912; served in France during World War I; associated with the judiciary board of the Veterans Administration; served on the staff of the Veterans Hospital in Dearborn, Mich.; died in the Charles Godwin Jennings Hospital July 14, aged 60; of peritonitis following rupture of a diverticulum of the colon.

Raymond Alexander Kinloch ⊕ Springfield, Mass.; University of Vermont College of Medicine, Burlington, 1903; member of the New England Obstetrical and Gynecological Society; on the staffs of the Wesson Memorial and Wesson Maternity hospitals; died July 5, aged 72, of heart disease.

Allan Oscar Kisner, Bethlehem, Pa.; College of Physicians and Surgeons, Baltimore, 1896; on the auxiliary staff of St. Luke's Hospital; died July 5, aged 82, of arteriosclerosis and bronchopneumonia.

Claude Ross Laird ⊕ Ingleside, Neb.; Creighton University School of Medicine, Omaha, 1913; member of the American Psychiatric Association; served during World War I; for many years on the staff of the Hastings State Hospital; died in the Soldiers' and Sailors' Home in Grand Island, July 5, aged 66, of uremia and heart disease.

Edward Nathaniel Lindquist ⊕ Culver City, Calif.; College of Medical Evangelists, Los Angeles, 1933; diplomate of the National Board of Medical Examiners; co-owner of the Community Hospital; died July 5, aged 42, in an airplane accident.

Thomas Russell Littlejohn, Sumter, S. C.; Medical College of South Carolina, Charleston, 1910; member of the American Medical Association; president of the Sumter County Medical Society; served during World War I; on the staff of the Tuomey Hospital, where he died July 26, aged 58, of cerebral hemorrhage.

Thomas E. Livingston, Portales, N. Mex.; College of Physicians and Surgeons, Keokuk, Iowa, 1887; died July 4, aged 86, of cerebral hemorrhage.

Herman Meyer Lynch ⊕ West Bend, Wis.; Northwestern University Medical School, Chicago, 1908; health officer; served during World War I; member of the county selective service board during World War II; on the courtesy staff at St. Joseph's Hospital in Milwaukee and the regular staff at St. Joseph's Hospital in West Bend, where he died July 8, aged 63, of aneurysm and rupture of the aorta.

Gustavus T. Lyon, Roswell, Ga.; Georgia College of Eclectic Medicine and Surgery, Atlanta, 1898; member of the American Medical Association; formerly a member of the state board of medical examiners; on the staff of the Crawford W. Long Memorial Hospital in Atlanta; died July 1, aged 75, of arteriosclerotic heart disease and nephritis.

John J. McGarrell, Baltimore; University of Maryland School of Medicine, Baltimore, 1908; died May 12, aged 64, of cerebral hemorrhage and hypertension.

Edward Louis Miller, Picher, Okla.; University Medical College of Kansas City, Mo., 1911; served during World War I; affiliated with the Picher Hospital; died July 18, aged 62, of angina pectoris.

Albert Crombie Nixon ⊕ Los Angeles; Western University Faculty of Medicine, London, Ontario, Canada, 1914; on the staff of the Children's Hospital; died June 15, aged 59, of cerebral hemorrhage and hypertension.

Joseph Tilford Scott ⊕ New Orleans; Medical Department of Tulane University of Louisiana, New Orleans, 1894; for many years affiliated with the U. S. Public Health Service; on the staffs of the Mercy Hospital and the Touro Infirmary; died July 5, aged 77, of coronary occlusion.

Charles E. Sharp, Elgin, Ill.; Chicago Homeopathic Medical College, 1895; Harvey Medical College, Chicago, 1900; died in the Sherman Hospital July 29, aged 86, of carcinoma of the stomach.

Wilbur S. Slaughter, Jonestown, Miss.; Memphis (Tenn.) Hospital Medical College, 1904; member of the American Medical Association; died July 14, aged 66, of heart disease.

Jane Gray Stone, Boston; Tufts College Medical School, Boston, 1911; died in the Massachusetts General Hospital May 6, aged 73, of pulmonary embolism.

Elma Janes Townsend, Madison, Wis.; Woman's Medical College of Baltimore, 1899; died in Maywood, Ill., July 2, aged 81, of coronary heart disease.

Harvey Clinton Upchurch, Dover, N. J.; College of Physicians and Surgeons, medical department of Columbia College, New York, 1893; died in the General Hospital July 21, aged 77, of coronary occlusion and hypertension.

Walter Edward Zielinski, Buffalo; University of Buffalo School of Medicine, 1917; member of the American Medical Association; served during World War I; bacteriologist for the city health department; died June 14, aged 57, of aortic insufficiency.

Vitamin D in Cutaneous Tuberculosis

In the section of dermatology Dr. J. Charpy (France) gave the results of vitamin D treatment in cutaneous tuberculosis; he introduced this treatment seven years ago. He now gives an adult 15 mg. of vitamin D in alcoholic solution twice a week for four weeks. He follows this with the same dose weekly for periods ranging from two months to two years. This treatment should be accompanied by a diet containing 1½ pints (670 cc.) of milk a day, with plenty of meat, fruit and vegetables. Fats should be taken sparingly and the salt intake much reduced, being omitted completely three days a week. The patient should take no alcohol or whole meal bread and should live in the open air. The good effects of treatment should be evident on the fifteenth day. If there was not improvement by then, failure of absorption must be suspected, or failure of tissue permeability, because of too much salt in the tissues. In successful cases there was no doubt about clinical cure; anatomic cure was more doubtful. If the treatment was pushed toxic symptoms were produced, which might culminate in acute nephritis.

Dr. G. B. Dowling (London) described his results from this treatment regimen, which he had adopted before he knew of Charpy's work. He gave doses of 150,000 units of vitamin D a day. He treated 39 patients to the end of 1945. Of these, 32 have been fully assessed; 18 are free from lupus and 9 improved, while 5 show no change. Since March 1946 he has treated 33 cases of cutaneous tuberculosis in adults and 11 in children. The adults had the disease an average of twenty years. Twenty-eight patients were discharged as free from lupus, but of these ten showed relapses, which responded to further treatment. In the early weeks of treatment the adult patients became worse and then began to improve. In one or two cases treatment with calciferol was followed by activation of a tuberculous focus in the lung. Dr. Dowling noted that Charpy reported nearly 100 per cent successes. His own results were not equal to this but were striking. On the other hand, others reported poor results, and it was hard to account for the great discrepancies.

Penicillin

At the opening session Sir Archibald Fleming, the discoverer of penicillin, discussed this substance. It was the first successful antibiotic and set a high standard which no other antibiotic had yet reached. He discovered it by accident in 1928, while studying the staphylococcus. He forgot to put the lid on one culture plate, which became contaminated by an air-borne mold. Until recently all the penicillin in the world was made from the pure cultures grown from this contaminant. Following the observation that the mold produced lysis of the staphylococci growing near it, experiment showed that it had a selective action on some bacteria. When the mold was grown in a fluid medium, the fluid underneath contained a differential antiseptic, which was named penicillin. Other molds tested did not have this property. It was found that solutions of penicillin would diffuse through a much greater thickness of agar than could the old fashioned antiseptics and, in contrast with all other antiseptics then known, would kill staphylococci without harming leukocytes. In those early days penicillin was extremely impure—the best batches had a potency of only 1.5 units per cubic centimeter. Research in the United States has produced strains with a far greater yield.

Fleming has urged that penicillin be given only when the infecting organism is sensitive to it. The main objection to oil and beeswax mixtures—that they solidify on cooling—has been overcome. But prolonged action can equally well be obtained by injecting large doses of an aqueous solution. The most dramatic success of penicillin has been against gonorrhea. It is the only drug that allows a patient to have an attack twice a week! Indiscriminate use of penicillin is to be deprecated, because it is possible, though not easy, to render a sensitive organism resistant. The chairman, Lord Moran, said that as regards syphilis it is not known what the remote results of treatment will be.

Professor R. V. Christie submittd a report on the results of treatment with penicillin in 269 cases of infective endocarditis at the fourteen centers set up by the Medical Research Council. A dosage of 500,000 units a day was the most successful. It was a mystery why some patients did not respond though their infecting organism was no less sensitive than that of others who recovered. If a patient relapsed after one course he was unlikely to respond to a second. Most relapses occurred within twenty days but might arise after a year of health. Foci of infection should always be attended to. After a follow-up of at least a year Professor Christie had determined that in 95 per cent of the cases the infection could be controlled, but 39 per cent of the patients would die later. Heart failure was the major cause of death, accounting for 56 per cent of the fatalities, uremia for 6 per cent, emboli for 11 per cent, hemorrhage for 8 per cent and uncertain causes for 19 per cent. The risk of complications was more serious than the risk of not responding to penicillin therapy. The most significant points in prognosis were the degree of heart failure and the state of nutrition. With severe cardiac failure the outlook was practically hopeless, and the death rate among emaciated patients was 87.5 per cent. A sufficient dietary of protein was therefore essential.

Vitamin D_2 in the Treatment of Lupus Vulgaris

Vitamin D_2 in an alcoholic solution, given per os, is claimed to cure completely and definitely tuberculosis of the skin. As stated by Professor Robert Debré at the scientific assembly of the Centennial Celebration of the American Medical Association, signs of intolerance through too strong doses have been seen. At one of the recent meetings of the National Academy of Medicine J. Charpy (Dijon) has explained the results of his research on the process of action of vitamin D_2; he thinks that a certain amount of vitamin D_2 increases the activity of intestinal phosphatases and that with stronger doses there occurred, moreover, activation of other phosphatases in the kidneys and in the bones, which produced intoxication.

He relies on two groups of facts:

1. Magnesium, an activator of alkaline phosphatases, supplements the therapeutic effect of vitamin D_2 without diminishing the margin of tolerance, if administered orally in the form of magnesium chloride (1½ Gm.) a little while before the vitamin D_2 is taken. However, intravenous magnesium sulfate (1½ Gm.) increases the effect of vitamin D_2 but diminishes the margin of tolerance. Why this difference of action? In the case of oral magnesium chloride the amount of magnesium in the blood does not sensibly vary and only the intestinal phosphatases are activated; by the intravenous administration of magnesium sulfate the renal and osseous phosphatases are stimulated at the same time.

2. Cysteine is a strong inhibitor of the phosphatasic action; Charpy and P. Pichat have observed that the daily injection of 0.001 Gm. of cysteine suppresses the therapeutic effect of a large dose of vitamin D_2 given orally in an alcoholic solution and, at the same time, the accidents due to intolerance. Therapeutic activity and intoxication are, then, two effects with a single cause. As a consequence, Charpy thinks that vitamin

D_2 reacts on the lupus not by itself but through products of the hydrolysis of the intestinal phosphastase transferred to skin by means of the circulation. The author has also reported a clinical experimental observation, in which an open tuberculous lesion, rich in Koch's bacilli, has been sterilized through a complex treatment consisting of (*a*) oral magnesium chloride, vitamins D_2, B_1, B_2 and C (ascorbic acid), phosphoric acid and nicotinamide and (*b*) direct contact of muscular adenylic acid.

New Books on Pulmonary Tuberculosis

Two remarkable books by G. Canetti, laboratory chief at the Cochin Hospital and assistant at the Pasteur Institute, have been published by Ernest Flammarion, 20 Rue du Vaugirard, Paris, (under the guidance of Professor Pasteur Vallery-Radot and Professor Agrégé J. Hamburger) in the collection of the Pasteur Institute.

"Koch's Bacillus in the Tuberculous Lesion of the Lung" sets forth the anatomicohistobacteriologic and clinical research on 1,500 cases for seven years. The author has examined the abundance and the rarity of the tubercle bacillus according to the various stages of tuberculosis He has found in histologic sections an average of 13 bacilli in one hundred fields in fibrinous alveolitis; only 6 in one hundred fields in solid caseation, but up to 150,000 in one hundred fields of caseation in process of softening. In the cavities (in the internal necrotic zone) there is an average of 8,000 in one hundred fields. The causes of these variations are unknown. Canetti thinks that they are probably ascribable to changes in the local conditions, which create a medium sometimes favorable, sometimes unfavorable to bacillary development.

"Tuberculous Allergy in Man" sets forth the results of research on 4,500 cases. Against the broader definition of allergy by Rist and others, the author adopts a restricted definition of allergy as a hypersensitivity which appears in the organism when first infected. He studies it in latent tuberculosis, in osteoarticular and cutaneous tuberculosis. He also studies the mechanism of allergy, which, according to him, does not yield any information which could be of profit for the diagnosis or the prognosis; its value is questionable. It is at the same time useful and noxious on account of the strong reaction which has an influence on the trend of phthisis. The primary role, as regards protection, belongs, according to the author, to the natural resistance of the organism. The evolvement of a precise test rendering possible the detection of subjects resistant to tuberculosis is of primary importance. The author believes it possible that subjects whose tuberculin reactions are negative after having been positive are endowed with a strong natural power of resistance contributing to the rapid sterilization of latent lesions.

Adnexitis

On the agenda was adnexitis. J. Dalsace emphasized the role of hysterosalpingography and of insufflations in the diagnosis and treatment of salpingitis. He insisted on the association of those two processes with conservative surgery of the oviducts. Y. Canel and P. Neumand demonstrated, on observation of thousands of cases, that 85 per cent of patients respond successfully to hydromineral treatment. R. Bougarel and H. Ezes reported 8 cases of salpingitis due to intestinal parasitism. Arnaldo de Moraes and João Bruno Lobo (Rio de Janeiro, Brazil) reported 68 cases of adnexitis treated with four consecutive applications (50 r each) of roentgen therapy. In 42 cases (64 per cent) they obtained extremely favorable results, in 16 (24 per cent) indifferent ones; 8 cases (12 per cent) have been failures. J. Delmas and Y. Andreani used with success local penicillin therapy associated with a *véhicule retard* and added vitamin H (biotin), which renders it effective against Escherichia coli. In a series of abscesses of the breast, they obtained spectacular results by the local use of penicillin and avoided surgical operation. The same authors reported 90 patients (50 post abortum and 40 post partum) prophylactically treated with great success by direct introduction into the uterus after obstetric proceedings (such as curettage) of an average of 5 Gm. (ten tablets) of sulfanilamide. The Congress has expressed several wishes, which have been forwarded to the public authorities: (1) that the Social Security Organization recognize adnexitis as a disease of long duration; (2) the creation by the Faculty of Medicine of a Gynecologic Certificate for the specialists of this branch, and (3) the inclusion of a sperm examination among other laboratory tests in the prenuptial examination because of the increase of male sterility (35 per cent).

Eleventh Congress of French Gynecologic Society

This Congress, at which twelve nations were represented, took place at Châtelguyon, May 31-June 3, 1947. The opening speech was delivered by the honorary president, Dr. J. C. Rubin of New York, representing the American Gynecological Society. He said among other things that: "Medicine is democracy in action; it knows of no barrier, no secret formula; the same biologic laws apply to kings as to ordinary citizens, to whites and Negroes, to aristocrats and laborers. True Medicine knows of no hatred. Nature in its different kingdoms offers a striking evidence of unity in diversity. Science, Democracy and Medicine are an absolute whole."

BUENOS AIRES

Sept. 10, 1947.

Transthoracic Injection of Streptomycin

According to a communication to the National Academy of Medicine, Drs. M. R. Castex, E. L. Capdehourat and C. Rechniewski injected streptomycin directly into the thorax in 2 cases of chronic pulmonary suppuration (a more precise characterization of the disease is not given) in which every other therapeutic procedure, including nebulization of sulfonamide drugs and penicillin, had been without success. They chose the transthoracic route to administer the small quantity of streptomycin available.

The sputum of the first patient showed, before this treatment, a flora particularly rich in gram-negative organisms (Klebsiella pneumoniae and coliform bacilli). After the transthoracic injections of streptomycin the bacterial flora diminished in quantity and quality. Both the aforementioned bacilli disappeared after the fifth injection, but after the eighth injection some gram-negative organisms reappeared (although in a small number) and did not disappear again until the end of the treatment (acquired resistance?). The presence of an effective amount of streptomycin in the sputum could be proved. The quantity of sputum diminished from 85 cc. per day to 25 cc. after the sixth injection, coincident with the disappearance of the gram-negative bacilli, but later on increased again.

In the second case also previous intrapulmonary injections (see The Journal, Oct. 5, 1946, p. 303) of sulfonamide compounds, neoarsphenamine and other agents—two hundred injections in all—had had a transitory effect (if any). With streptomycin therapy the number of organisms diminished considerably following the third injection and remained so until the end of treatment. The gram-negative bacilli disappeared at the same time but reappeared in a much lower concentration after the seventh injection and remained so until the treatment was terminated.

From their observations the authors conclude that the action of streptomycin is only transitory and bacteriostatic but not bactericidal. After the treatment had been terminated, the bacterial flora reappeared. The pyogenic process of the lung had not been cured, although the streptomycin had been diffused efficiently in the morbid focus. The injection of 1 Gm. of the drug is adequate for twenty-four hours, while for other routes of injection greater amounts are necessary. This circumstance seems of importance also with respect to disagreeable side reactions provoked by greater quantities of the substance. The frequency of the injections depends on the clinical and bacteriologic data obtained. According to the observations in the 2 cases mentioned, one transthoracic injection per day is sufficient (contrary to the need for more intramuscular and intravenous applications). The transthoracic injections should be continued after the gram-negative bacteria have disappeared, to make the cure certain. If during treatment the gram-negative bacteria reappear, the dose of streptomycin should be increased, because the reappearance indicates a certain degree of resistance to the drug. In both the observed cases the application of streptomycin could not be continued according to these rules due to the lack of the drug.

Intra-Articular Administration of Penicillin

Occasionally cases of acute articular processes are seen which affect only one or two articulations but these with much intensity (and not many joints in a more superficial degree). It is the form which Chauffard designated rheumatic pseudophlegmon. According to a communication of Dr. Guido Costa Bertani to the Society of Internal Medicine of Buenos Aires it is characteristic for this condition to be resistant to any usual form of treatment. A quick therapeutic success, however, is necessary to overcome the great danger of cartilaginous destruction. Sulfonamide compounds are without effect; a gold preparation is somewhat better but not always possible to administer, due to the sensitivity of many patients to this substance, and sometimes dangerous. Penicillin given intramuscularly or intravenously also has little effect (if any). Therefore Dr. Costa Bertani tried the intra-articular administration of penicillin directly into the affected joint. After obtaining a good result in the first patient (who was absolutely resistant to any other treatment) with only two intra-articular injections, this method has been tried in more cases (4 of which are described in extenso) with complete and immediate success. The dosage of penicillin varies between 5,000 and 20,000 Oxford units (10,000 per cubic centimeter). It is supposed that the rapid improvement is exclusively due to the intra-articular administration of penicillin.

Cardiology as a Specialty

The Faculty of Medicine of Buenos Aires has created the title of Cardiologist. To be qualified as such the candidates must be an M.D. at least two years and attend a special instruction course of two years' duration, practical as well as theoretic, which includes pathologic anatomy, physiopathology, semiology, pharmacology and therapeutics, radiology, electrocardiology and cardiologic clinic. The number of participants is limited; they pay each year 100 pesos for matriculation and 720 pesos for the training. Seventy per cent of this amount is distributed among the teachers, who must be recognized specialists elected by the director of the course, who himself must be a professor of the faculty and is appointed by a special commission of the same. Twenty per cent is for instruction expenses and the last 10 per cent for administrative expenses. After one year the candidate has to pass an examination of "sufficiency," to which he is admitted only when he has attended at least 80 per cent of the lectures and has satisfactorily completed all the practical work. Without having passed the examination at the end of the first year he cannot register for the second year.

Sterility Due to Absence of Germinal Epithelium

Drs. E. B. del Castillo, F. A. de la Balze and A. Trabucco observed 5 cases of a new syndrome, the principal characteristics of which are sterility and small testicles in men who are otherwise normal. Biopsies of the testicles proved the complete absence of the germinal epithelium while Leydig's cells were normal; the tubules likewise had walls of normal structure and contained apparently normal Sertoli's cells. To explain the absence of the germinal epithelium the authors suppose—as a hypothesis—that the primary gonocyte did not penetrate in the primary testicle. The follicle-stimulating hormone in the urine was of normal quantity, the 17-ketosteroids somewhat diminished. They suppose that Sertoli's cells are the source of a hormone which is similar to estrogen which controls the production of the follicle-stimulating hormone of the hypophysis.

Ulcer of Cornea Caused by Thiocyanate

In 1944 Drs. Juan M. González and José Dorning Muñoz of the Spanish Hospital at Rosario reported 10 cases of ocular complications during the treatment of hypertension with potassium thiocyanate (of which 1 was ulcer of the cornea). They therefore advised an average dose of no more than 0.3 Gm. (0.2 to 0.4) per day, with which they had never observed toxic manifestations of importance, especially when given intermittently (during four or five days, then interrupted for two or three days). But in spite of these precautions 3 more cases of corneal ulcer have been observed by the same authors in the last two years. They admit that these observations are rather infrequent and that they have not been able to establish exactly the relation of cause and effect between the medicament and the lesion. However, it seems notable that the ocular alterations appeared simultaneously with the administration of the thiocyanate and disappeared when this medicament had been discontinued. The character of the lesions was benign with restitution ad integrum in a few days.

Prominent Visitors at Buenos Aires

It seems to us a good symptom of the intensified scientific interchange that—apart from eminent specialists who will be mentioned under "Brief Items" and who are particularly Americans—some prominent physicians have visited the Argentine during the last weeks. The first of them has been Dr. Morris Fishbein, who in his very active way visited in a short time all the important scientific institutions of Buenos Aires. He has been received by all the Argentine leaders of medicine, addressed the Academy of Medicine, speaking on recent progress in medicine, has been made a corresponding member of the Argentine Medical Association and made, indeed, a great lot of new and sincere friends.

Prof. Dr. de Gennes of the Faculty of Medicine of Paris read several papers on endocrine questions, particularly on pellets of hormones and on the endocrine treatment of hypertrophy of the prostate.

Professor Louis Michaud, director of the medical clinic of the Faculty of Lausanne (Switzerland) read papers on the respiratory function, the metabolism of iron, hereditary problems in neurology and some kidney problems, describing the research by his clinic during the last years. He also became a corresponding member of the Argentine Medical Association.

Dr. Georges Duhamel, writer, who is also a physician, addressed the National Academy of Medicine, speaking of the merits of the French investigator Charles Nicolle. He has been made an honorary member of the academy.

Brief Items

Prof. Dr. Domingo Brachetto Brian has been appointed by the government new director of the Instituto de Medicina Experimental, replacing Dr. Angel H. Roffo, who had to retire some months ago and died on July 24, at the age of 65. Dr. Brachetto Brian, who is a pathologist, studied in France with Roussy, Pierre Marie and several well known surgeons and also in the Curie Institute. He is professor extraordinary of the Faculty of Medicine of Buenos Aires and since 1936 has been director of the department of pathologic anatomy of the Hospital Ramos Mejía in Buenos Aires.

Correspondence

COMPLEX SIMPLE FRACTURE

To the Editor:—Realizing that the term "simple fracture" as generally defined is thoroughly inadequate to describe the trauma received in many so-called simple fractures, I have added a new definition to the simple and compound fracture nomenclature, i. e., "complex simple fracture" (Key, J. A., and Conwell, H. E.: The Management of Fractures, Dislocations and Sprains, ed. 4, St. Louis, C. V. Mosby Company, 1946, pp. 41-43).

A complex simple fracture is a fracture which is not compound but which has received severe trauma to either or all of the surrounding soft structures, i. e., skin, muscles, blood vessels and nerves. The bony fragments usually are displaced to a marked degree.

"Complex," as defined by "Webster's New International Dictionary," unabridged, is as follows: (1) an assemblage of related things; (2) a whole made up of complicated or interrelated parts.

The complex simple fracture should be further described as to the type of bony injury, for example: complex simple fracture (transverse, comminuted, spiral or oblique, as the case may be).

Through personal contacts and correspondence with the personnel of the three National Fracture Committees (American Medical Association, American College of Surgeons and American Academy of Orthopaedic Surgeons) with reference to their opinions and the necessity for such new fracture term or definition, there was unanimous agreement that such a definition of complex simple fracture was a necessary one and should be generally accepted and used in its broad meaning.

I make an appeal that this new fracture definition or its relative equivalent be used by the members of the medical profession. Besides expressing more adequately the pathologic process in such type fracture it will mean improved records for the hospitals and convey a better description of the fracture to the insurance companies, compensation boards and other related agencies, thereby being of much help to the patient, the physician and every one concerned.

I will appreciate any opinion or suggestions relative to the foregoing.

H. Earle Conwell, M.D., Birmingham, Ala.

ALLERGIC REACTIONS TO TYPHOID (T. A. B.) VACCINE?

To the Editor:—During the past months I have been variously interrogated whether I had any knowledge of allergic reactions after typhoid or T. A. B. vaccination. So far I have always given a negative answer. In numerous cases fainting was allegedly observed a few hours after the injections. In 1 case it was reported that a dangerous collapse had taken place.

When asked why an allergic case should be suggested, physicians based their diagnosis on Theodore J. Curphey's paper "Fatal Allergic Reaction Due to Influenza Vaccine" (The Journal, April 12, p. 1062). In that report a previous paper of V. E. Roth is cited: "Thus Roth reported 9 cases of allergic reactions to typhoid vaccines, in only 4 of which the patient gave a reliable history of allergy to egg protein." As typhoid vaccine is not prepared with any egg products I supposed a misprint. Roth's paper in the *United States Bulletin of the Army Medical Department* 1945 was inaccessible to me, so I looked up its abstract in The Journal (July 21, 1945, p. 904), where I gathered that the reported 9 cases of allergic reaction were derived not from typhoid but from typhus vaccine. This proves that the fears of an alleged influence of typhoid vaccine of allergic reaction are utterly baseless.

M. J. Gutmann, M.D., Jerusalem, Palestine.

THE EPIDEMIOLOGY OF POLIOMYELITIS

To the Editor:—Sabin asks in his article on "The Epidemiology of Poliomyelitis" (The Journal, June 28) Why did paralytic poliomyelitis become an epidemic disease only a little more than fifty years ago, and as such why does it seem to be affecting more and more the countries in which sanitation and hygiene, along with the general standard of living, are presumably making the greatest advances, while other large parts of the world, regardless of latitude, are still relatively unaffected?

My answer:

Let us take the hypothesis that a B hypovitaminosis is a disposing factor for poliomyelitic paralysis (see C. Braendli-Wyss: Propositions for Prophylaxes of the Poliomyelitic Paralysis, *Schweiz. med. Wchnschr.* **2:**40, 1945). The general B hypovitaminosis induced by the milling of fine flour and other changes in nutritional habits is followed in time by the appearance of the first poliomyelitic paralysis epidemic. Apart from that the countries with the best developed hygienic conditions are those with pronounced B hypovitaminosis. I am sure this is only one part of the problem, but I think it would be of general interest to discuss this in The Journal.

In any case it would be worth while to carry through an experiment on a large scale with your incomparable possibilities in schools or other institutions in your country by additional vitamin B supply.

C. Braendli-Wyss, M.D.,
Burgdorf, Switzerland.

IMMUNIZATION PROCEDURES IN PEDIATRICS

To the Editor:—In the discussion to the paper "Immunization Procedures in Pediatrics" given by J. J. Miller Jr. (The Journal, July 26), Dr. Thelander spoke about the variability of the capacity to be immunized as an important factor of vaccination. We have studied this variability by means of several thousand titrations of antibodies in vitro and in vivo and we have shown that the curve obtained by plotting logarithms of titer against incidence is a curve of normal distribution; this predisposition for immunity is hereditary and is different for different antigens in the same subject; i. e., a person who is prone to produce a good antibody response to one antigen does not show, on the average, a similar predisposition to produce other antibodies. Some exceptions to this rule are interesting only from a theoretical point of view (*Boll. Ist. Sieroter, Milanese* **24:**215, 1945, IV International Congress of Microbiology).

I have read with great interest the conclusions drawn by Dr. Miller and Dr. Thelander on the subject of immunization in older ages. In several Italian towns we have used an oral method of restoration of diphtheria immunity in adults and have obtained with the vaccine we have prepared good results: one 100 Lf tablet dissolved in the mouth daily for seven days was sufficient in more than 90 per cent of the adults to provoke a striking increase of antitoxin in the blood serum (in many cases from < 0.02 unit to more than 2 units) (*Riv. Ist. Sieroter. Italiano* **22:**49, 1947).

To avoid confusion in the American readers of European literature, I would like to point out also that the standardization of H. pertussis vaccines using the European standards of turbidity (Wellcome opacimeter, etc.) does not correspond to the American one. European vaccines have a concentration of bacteria approximately three times as strong as the American vaccines having the same labeled strength.

E. Carlinfanti, Naples.

Istituto Sieroterapico Italiano.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Workman's Compensation Act: Release Based on Untrue Statements of Physician May Be Set Aside.—The plaintiff filed an action to set aside a release made in a compromise settlement of an industrial accident injury. From a judgment for the plaintiff the defendant appealed to the Court of Civil Appeal of Texas.

The plaintiff suffered an injury in the course of her employment when some steel dust and shavings from a machine she was operating were blown into her eyes. After being under the care of a physician selected by the employer for some five weeks, during which time she did not work because of her eye condition and headaches, the defendant's claim agent called on her, said he had been informed that she had been dismissed by the physician and wanted to discuss a settlement of her claim. The plaintiff denied the dismissal, answering that she had another appointment the following Monday, and the claim agent left saying he would see the physician. A few days later he came back with the same information. The plaintiff again questioned the statement, whereupon the claim agent asked her to call the physician on the phone which she did. She said she recognized the doctor's voice; he told her that she should have been already advised about a dismissal, then dismissed her, saying that her eyes were all right and "It would be all right for me to settle." Accordingly she entered into a compromise settlement and signed the release in question. It subsequently developed, however, that the plaintiff was slowly losing the use of her eyes due to deterioration of the optic nerve; that there were scratches on the eyeball surface; that both eyes were infected, the infection going down to the corneal margin; that the plaintiff had photophobia, with evidence of injury to the cornea of the eye by particles of steel; that the plaintiff's trouble was slow deterioration of the optic nerve and inability of the eyes to fuse images; that the defect was in the nerve and could not be cured by glasses; and that the injury sustained at the plant reasonably caused the condition of the plaintiff's eyes.

This action, said the Court of Appeals, is based on the well settled equity doctrine that representations of an existing fact or condition by a releasee's doctor, relied on by the releasor, are sufficient grounds for avoidance if the representations are proved to be untrue in fact. The defendant, however, contended that this principle was not applicable because the evidence showed that the plaintiff knew in her own mind at the time she signed the release that her eyes were not getting well. The court said, however, that "The fact that the releasor had doubts as to the correctness of the representations of the physician of the releasee regarding the extent of his injuries will not prevent the setting aside of the release, on the theory that in executing it the releasor acted on his own judgment, and not on that of the physician, if in fact the representation of the latter did in fact influence him in making the settlement." On a review of all the evidence, the court was of the opinion that the judgment in favor of the plaintiff setting aside the release should be affirmed.—*Associated Employers Lloyds v. Aiken, 201 S. W. (2d) 856 (Texas, 1947).*

Railroad Hospital as Public Charity Exempt from Taxation—Pulaski County, the City of Little Rock, the Little Rock Special School District and an individual property owner filed a petition with the Arkansas Public Service Commission to have the property of the defendant hospital association placed on the assessment roll for ad valorem taxes. The Public Service Commission made the order requested by the plaintiffs, which order was affirmed by the Pulaski Circuit Court, so the defendant appealed to the Supreme Court of Arkansas.

Article 16, section 5, of the Arkansas constitution says, in part, ". . . the following property shall be exempt from taxation: . . .. buildings and grounds and materials used exclusively for public charity." And the defendant claims that its property is exempt under the aforequoted portion of the constitution.

Defendant is a benefit association organized under the laws of Missouri and composed of the employees of the Missouri Pacific Railroad Company and the Missouri Pacific Transportation Company. Defendant owns the hospital in Little Rock, and the employees of the railroad and transportation companies support the hospital by contributions from their wages and salaries each month and these employees have absolute and exclusive control over the hospital. The hospital is principally opened to retired employees of these companies and to members of their families, but, in addition, the hospital receives some people who become sick or are injured on the property of the railroad or transportation company. The hospital does not "go out and take in the public generally that might come in and ask for admission." The employee contributions are fixed by the board of trustees of the hospital, based on a scale depending on the amount of wages of each employee. The assessments are made to meet the requirements of the hospital and, in the event that the hospital accumulates a surplus, the assessments are reduced or temporarily suspended.

These facts, said the Supreme Court, show that the property is not used "exclusively for public charity." In a prior Arkansas case the Supreme Court held the following to be some of the essentials (existing in that case) necessary to allow exception of property "used exclusively for public charity": A. The institution was opened to any worthy sick person regardless of ability to pay. B. No funds were diverted from the institution and whatever profit was realized from those who paid went to the benefit of those who could not pay, to extend and enlarge the charity of the hospital. Neither of these two essentials, the court pointed out, is present in the case at bar. The defendant hospital is not open to "any worthy sick person"; it is open only to the Missouri Pacific employees, their families and persons who may become sick or injured on Missouri Pacific property. Furthermore, if the hospital accumulates a surplus it is returned to the members by reducing or temporily suspending assessments. In short, the proof shows that the hospital is not used "exclusively for public charity" and the use is the determining factor.

Continuing, the court said that a most enlightening case, construing the Arkansas constitutional provision as applied to a hospital operated for benefit of railway employees, is *St. Louis Southwestern Railway Company v. Yates, 23 F. (2d) 283.* In that case the United States Circuit Court of Appeals of the Eighth Circuit decided that a hospital in Texarkana, Ark., was not exempt from taxation. The court said "Funds to support the institution are to be obtained by assessments, based on a wage earning scale, collected monthly from the employees. There are other provisions which emphasize those above quoted or outlined but sufficient has been said to show the general plan of the trust to be that the use of the property is confined to the employees (and their dependents) of appellant and its affiliated lines. The public in general, nor any part thereof nor any indefinite class have any right to any use in this property and it is in no wise supported by any charitable gifts or donations, but only by the direct beneficiaries thereof and by contributions, in the form of loans, from the railways whose employees are protected. In short, it is merely the familiar plan of a hazardous business providing hospital and medical services for those engaged therein. It seems to us that this is clearly not a usage 'exclusively for public charity.' . . ."

The defendant relied most strongly on act 40 of 1931 as granting the exemption from taxation. This act provides: "All corporations or institutions heretofore or hereafter organized, created and operated as a hospital for the purpose of treating the members of said organization and others, not leased or otherwise used with a view of profit, are hereby declared to be institutions of public charity and shall be free from taxation." But the vice of the defendant's argument in reliance on this act, said the Supreme Court, lies in the unconstitutionality of the act as applied to the facts of this case. Article 16, section 5, of the constitution provides what property is exempt from taxation; article 16, section 6, provides: "All laws exempting property from taxation other than as provided in this constitution shall be void." When we held as we have above that the defendant's property was not "used exclusively for public charity," then article 16, section 6, of the constitution strikes down any legislative attempt to grant defendant any exemption from taxation. We therefore conclude that act 40 of 1931 is unconstitutional in so far as it attempts to grant tax exemption to property not exempt under article 16, section 5, of the constitution and for that reason does not support the defendant in this case.

Finally, the defendant cited orders of the Pulaski County Court, made in 1925 and 1931, and an order of the Arkansas Tax Commission, made in 1929, each declaring defendant's property to be exempt from taxation and claimed that these orders rendered res judicata any and all questions as to taxability of defendant's property in the present proceedings. We hold, said the court, that a judgment rendered in one year, holding property to be exempt from taxes because "used exclusively for public charity," is not res judicata regarding the taxes of the property for a subsequent year. The great weight of authority is to the effect that an adjudication on liability for taxes of one year is no bar to an action for taxes for a subsequent year. We therefore hold that the defendant's plea of res judicata is without merit.

A dissenting opinion states, in part. "It will be observed that the exempting provisions of the constitution do not attempt to define 'public charity,' so as I view it, the present case presents this question: Can the legislature within reasonable limitations find and declare as the public policy of this state what constitutes public charity and what types of institutions shall be declared institutions of public charity. I think it has that power. Certainly, the legislature of this state has the power to, and does, declare the state's public policy and when, as here, it has by legislation declared the state's public policy to be that all corporations or institutions coming within the provisions of act 40, supra 'are hereby declared to be institutions of public charity and shall be free from taxation' it was, it seems to me, acting within its powers and this court would not be warranted in striking down this legislation as being in contravention of the constitution."

The judgment of the circuit court holding the hospital association property to be taxable was affirmed.—*Missouri Pacific Hospital Association v. Pulaski County, 199 S. W. (2d) 329 (Ark., 1947).*

Unauthorized Autopsy—Mistake in Identity of Corpse.—The plaintiff sued for damages alleged to have been sustained by virtue of the performance of an unauthorized autopsy on the body of her deceased husband. The defendants are the manager of health and charity and ex officio coroner and superintendent of the Denver General Hospital, the deputy coroner in charge of the morgue and the pathologist for the Denver General Hospital. From a judgment for the plaintiff, the defendants appealed to the Supreme Court of Colorado.

The plaintiff's husband and one William Lloyd were patients in the Denver General Hospital and occupied adjoining beds in the same room. Both men died on the same day, just five minutes apart. Pursuant to the rules and regulations of the hospital, the room nurse, who had been taking care of both patients, prepared death tags for them but "through mistake or inadvertence" she attached the tag prepared for Lloyd to the body of the plaintiff's husband. Following the deaths, the Lloyd family consented in writing to an autopsy on his body, but the plaintiff refused to consent to an autopsy on the body of her husband. Because of the mistake in the tags, however, the wrong body was delivered to the morgue and consequently the defendant Williams, pathologist at the hospital, with no knowledge of the circumstances, proceeded mistakenly to perform an autopsy on the body of the plaintiff's husband. The autopsy was performed in a proper and scientific manner.

The court first pointed out that the city itself was not liable. Municipal corporations, said the Supreme Court, exercise two classes of powers, "one . . . is of a public and general character, to be exercised in virtue of certain attributes of sovereignty delegated to it for the welfare and protection of its inhabitants; the other relates only to special or private corporate purposes, for the accomplishment of which it acts, not through its public officers as such, but through agents or servants employed by it. In the former case its functions are political and governmental, and no liability attaches to it, either for nonuser or misuser of power; while in the latter, it stands upon the same footing with a private corporation, and will be held to the same responsibility with a private corporation for injuries resulting from its negligence. . . . The authorities are practically agreed in placing certain general duties in the class that is governmental, and among those is the general duty of the preservation of the public health." Considering, continued the court, that the hospital, where the events upon which plaintiff relies occurred, was maintained and operated "for the purpose of preserving and maintaining the health of the people of the said City and County of Denver," we are pursuaded that the municipal entity was carrying on in its governmental, not its corporate, capacity, hence would not be liable.

Likewise, continued the court, those subjected to action here must stand absolved from liability. Schwalb, the manager, Economy, the deputy coroner, Williams, the pathologist, and the nurse who erred in attaching death tags, all were employees of the identical employer, the City and County at Denver. The basic error was that of the nurse, who was not made a party defendant. Defendants Schwalb and Economy had no part in what occurred, did not order or direct it, or even have knowledge thereof. Defendant Williams proceeded in accordance with information made manifest in apparent and usual course, and, so far as appears, without any wantonness, evil intent or wrongful purpose. In such circumstances, what he did was not actionable. The occurrences, clearly resulting from untoward happenings, were most unfortunate and regrettable. So far as revealed, however, all were the logical result of lack of care of the nurse, who was not made a party defendant. "The doctrine of respondeat superior applicable to the relation of master and servant does not apply to a public officer so as to render him responsible for the acts or omissions of subordinates whether appointed by him or not, unless he, having the power of selection, has failed to use ordinary care therein, or unless he has been negligent in supervising the acts of such subordinates, or has directed or authorized the wrong." In order for these exceptions to the rule to have consideration, however, the court concluded, they must be alleged in the complaint, which was not done in this case. Accordingly the judgment in favor of the plaintiff was reversed.—*Schwalb v. Connely, 179 P. (2d) 667 (Colo., 1947).*

Medical Examinations and Licensure

COMING EXAMINATIONS AND MEETINGS

BOARDS OF MEDICAL EXAMINERS
BOARDS OF EXAMINERS IN THE BASIC SCIENCES

Examinations of the boards of medical examiners and boards of examiners in the basic sciences were published in The Journal Oct. 18, page 452.

NATIONAL BOARD OF MEDICAL EXAMINERS

National Board of Medical Examiners: *Part III.* New Haven, Jan. 7-9; New York, Jan.; San Francisco, Dec. 16-18; Washington, Nov. 11-13. Exec. Sec., Mr. Everett S. Elwood, 225 S. 15th St., Philadelphia 2.

EXAMINING BOARDS IN SPECIALTIES

American Board of Neurological Surgery: *Oral.* Chicago, May or June. Final date for filing application is Feb. 1. Sec., Dr. W. J. German, 310 Cedar St., New Haven, Conn.

American Board of Obstetrics and Gynecology: *Part I. Written.* Various Centers, Feb. 6. Final date for filing application is Nov. 1. Sec., Dr. Paul Titus, 1015 Highland Bldg., Pittsburgh 6.

American Board of Orthopaedic Surgery: *Part I.* April-May. Applications are accepted for the next examination until Jan. 15, 1948. Sec., Dr. Francis M. McKeever, 1136 W. 6th St., Los Angeles 14.

American Board of Pediatrics: Dallas, Dec. 5-7. Philadelphia, Jan. 9-11. Sec., Dr. Lee F. Hill, 718 Royal Union Bldg., Des Moines 9.

American Board of Plastic Surgery: Examinations are given in April and November of each year in the home town of applicants. Sec., Dr. Robert H. Ivy, 1930 Chestnut St., Philadelphia.

American Board of Psychiatry and Neurology: *Oral.* May 1948. Final date for filing application is Feb. 15. Sec., Dr. F. J. Braceland, 102-110 Second Ave., S.W., Rochester, Minn.

American Board of Radiology: *Oral.* Chicago, June 1948. Final date for filing application is March 1. Sec., Dr. B. R. Kirklin, 102-110 Second Ave., S.W., Rochester, Minn.

American Board of Surgery: *Written.* Various Centers, March. Final date for filing application is Dec. 1. Sec., Dr. J. S. Rodman, 225 S. 15th St., Philadelphia 2.

American Board of Urology: Chicago, February. Final date for filing application is Nov. 1. Sec., Dr. Harry Culver, 1409 Willow St., Minneapolis 4.

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1937 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied with stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

*Islet Cell Tumor of Pancreas in Newborn Infant (Nesidioblastoma). H. Sherman.—p. 58.
Diphtheria of Esophagus: Case Involving Stomach and Tongue. A. L. Hoyne.—p. 80.

Immunization Against Pertussis. — Adams and his co-workers studied a selected group of mothers and babies who were followed at approximately monthly intervals throughout the first year of the infant's life. Infants were given three inoculations consisting of phase I superconcentrate vaccine, 2.5 cc. (40 billion organisms per cubic centimeter) or a total dose of 100 billion organisms given at weekly or monthly intervals. The dosage schedule was 0.5 cc., 1 cc. and 1 cc. Mothers who were immunized during the last trimester of pregnancy were given three inoculations at two week intervals for a total of 100 billion organisms. With weekly inoculations good antibody titers could be demonstrated in over half of the infants by the age of 1 month to 6 weeks. Monthly inoculations gave a slower but more permanent rise. A combination of the two procedures might offer the best chance of early protection to the infant. Increased dietary protein did not enhance the infant's capacity to form antibodies. Specimens of cord blood from mothers immunized in the last trimester of pregnancy contained antibodies but in somewhat lower amounts than the mother's serum. This antibody titer is gradually lost by the infant during the first six months of life. One hundred and forty-two pairs of specimens of antepartum and cord blood from unimmunized mothers were tested. Hemophilus pertussis antibodies were absent in both specimens in 109 pairs. Hemophilus pertussis antibodies were present in colostrum but in lower titer than in the maternal or cord blood; their significance in the human being is probably negligible.

Secondary Pancreatitis.—Véghelyi reports 1 case of mild pancreatitis following parotitis in a boy aged 4 years, 1 of severe pancreatitis following scarlet fever in a girl aged 7 years and a third case due to parotitis in a boy 4½ years of age who died. Pancreatitis, contrary to the general belief, is a frequent complication of certain diseases. It may subside without stormy symptoms, and only the diminution of some enzymes, especially of lipase, and the resulting deficiency condition leading to celiac syndrome may point to it. It is important that the condition be diagnosed in its earliest stage, as the process is no longer reversible after it has become chronic. In such cases the patients require large doses of pancreatic extracts or enzyme preparations and an almost fat-free diet. Milk can render good service if gastric lipase is present. Parenteral administration of vitamins A, D and K is of importance.

Islet Cell Tumor of Pancreas.—In Sherman's case of spontaneous hypoglycemia due to insular tumor of the pancreas (nesidioblastoma) in a newborn infant twitchings and convulsions were observed twenty-four hours after delivery. There was early a good response to administration of dextrose and injection of epinephrine, with a dextrose tolerance curve demonstrating rapid removal of the circulating glucose. Extrapancreatic causes of hypoglycemia were excluded. The mother was nondiabetic. A clinical diagnosis of hyperinsulinism was made and an exploratory laparotomy was performed. Neither resection nor biopsy of the pancreas was performed by the surgeon because the gland appeared normal in size, contour and consistency. This error has been stressed. The necropsy revealed typical islet cell adenoma, almost microscopic in size, and yet the active hormone secreted by it was either so great in amount or so potent in its effect as to cause a fatal outcome; the supportive treatment kept the patient alive for six and one-half weeks despite the severity of the convulsions. The mother's symptoms, including fatigue, somnolence and excessive sweating during the latter part of gestation, are suggestive of a hypoglycemic effect on the mother by the excessive insulin-secretory activity of the fetal pancreatic adenomatous tissue. Routine determinations of sugar in the blood should be made in the neonatal period and in pregnant women with symptoms suggestive of hypoglycemia in the last trimester.

Cheese and Its Relation to Disease.—Fabian states that since 1883 there have been reported in the United States and Canada 59 epidemics with 2,904 cases of disease and 117 deaths in which cheese was the causal factor. There is reason to believe that this represents only a part of the disease caused by cheese. The organisms most commonly associated with cheese-borne infections are members of the Salmonella group such as Salmonella aertrycke, schottmülleri, typhosa, suipestifer, typhimurium and choleraesuis; Staphylococci such as Staphylococcus albus and aureus; Brucella melitensis and Clostridium botulinum. Contrary to the opinion of many cheese makers, pasteurized milk makes a consistently higher scoring and better flavored Cheddar cheese than does raw milk. Cheese made from pasteurized milk can be ripened in about half the time required to ripen that made from raw milk, because it can be held at a higher temperature. There are seven states and Canada that now require cheese to be made from pasteurized milk or cream or to be held in storage for periods ranging from sixty to one hundred and twenty days in lieu of pasteurization. The sixty day holding period is considered too short, because pathogens may survive this storage period, especially if the cheese is held at low temperatures, 40 to 50 F. (5 to 10 C.). A ninety day holding period is considered preferable and one hundred and twenty days still better. All milk used in making soft cheeses should be required to be pasteurized, because many soft cheeses cannot be held for sixty days without spoilage or deterioration in quality.

Radioactive Phosphorus as External Therapeutic Agent. —Despite the obvious possibilities of using radioactive phosphorus (P^{32}) solution for external application to the skin, difficulties were encountered by Low-Beer in developing a technic which would insure exactly reproducible exposures and reactions. After experimentation with absorbent cotton, petrolatum, wool fat, blotting paper, acacia, higher alcohols and other substances, it was found that ordinary thin blotting paper is a most suitable vehicle. Blotting paper of known dimensions soaked in measured amounts of radioactive Na_2HPO_4 (sodium phosphate) solution, and dried, can be applied easily to any part of the skin. After preliminary experimental studies, about 400 skin lesions have been treated by the external local application of radioactive phosphorus. The lesions included carcinoma, hyperkeratosis, warts and hemangiomas. Over 90 per cent of the lesions disappeared. The author is aware of the inadequacy of expressing the dose by giving the amount of the radiating source and the time of exposure. At present this seems to be the least confusing and misleading dosage determination. The ultimate aim is to express the dose in some unit which will reveal more about the energy dissipated in the tissues. There is no intention to advance the method described in competition with long-established procedures. The present study has served to emphasize the usefulness of one of the many by-products of the chain-reacting piles established for the production of plutonium and uranium 235.

Retention of Radioactive Iodine in Thyroid Carcinoma. —Marinelli and his associates state that tissue sections and radioautographs from 19 cases of thyroid carcinoma have been studied during the past three years at the New York Memorial Hospital. Tracer or therapeutic doses of radioactive iodine are administered to the patient by mouth. Within twenty-four to forty-eight hours the surgical procedure is carried out. Blocks of tissue about 2 to 3 mm. in thickness are fixed in 10 per cent solution of formaldehyde. Wherever possible, blocks of noncancerous thyroid are included. The tissue blocks are dehydrated in dioxane and impregnated with paraffin. Thin sections are cut with a microtome, and these are dried in an oven or over a flame. After the sections are dried the paraffin is removed by passing the sections through several changes of fresh xylene. The exposed surfaces of the deparaffinized sections are then placed directly against the emulsion surface of a photographic plate or roentgen film. Among the 19 cases there were 10 in which the presence of radioactive material was detectable by radioautographic determinations. Five of these were examples of benign metastasizing struma. The remaining 5 had the structure of follicular adenocarcinoma. However, the reporting of positive observations in 10 of 19 cases of thyroid carcinoma is misleading because many of these 19 cases were selected. On the basis of present results and the estimation of the relative frequency of the various types of thyroid carcinomas approximately 15 per cent of thyroid cancers may be expected to accumulate radioactive iodine. Radioautographs do not indicate the exact distribution of radiation in a tumor, because they are obtained from radiation originating in a few microns of tissue and not in a tissue block of thickness comparable to the range of the beta particles. Since the isotopes of radioiodine emit gamma rays, there remains the possibility of administering the isotopes in amounts sufficient to deliver gamma radiation throughout heterogenous tumors. Therapeutic attempts now in progress will provide the answer to this question.

Cranial Manifestations of Fibrous Dysplasia of Bone.— Windholz says that numerous contributions to the knowledge of polyostotic fibrous dysplasia have established the fact that the skull is frequently involved in this disorder. Roughly, in 10 cases of monostotic skeletal involvement 1 cranial case has been recorded. In moderate skeletal involvement about half the cases show skull changes. In severe skeletal disease the skull participates constantly. Occasionally the skull exhibits the only manifestations of the disease. Pathologic and roentgenologic evidence of foci of the disease are in limited cranial manifestations—small, simple, cystlike bone blisters in the vault. In more advanced cases localized deformities with translucencies and densities within the deformed areas are observed. In later stages extensive, dense, bony islands and spicules become visible in the expanded parts. In severe involvement the entire vault, the base of the skull and the facial skeleton are deformed. Bone deposits are maximal and are localized mainly at the base of the skull and in the face. Prior to the differentiation of fibrous dysplasia from related conditions, misinterpretations were frequent. They were classified as cranial hyperostosis or, if localization was unilateral, as hemicraniosis, hemihypertrophy, unilateral hyperostosis, unilateral von Recklinghausen's disease, osteitis fibrosa cystica of the skull and the like. Most of the advanced cases have been reported as leontiasis ossea. There are indications that skull specimens known as leontiasis ossea were actually fibrous dysplasia. The basic tissue change is replacement of the diploe by connective structures (visualized roentgenographically as translucencies) in which irregular, poorly or completely ossified, nonlamellated bone tissue may develop (visualized as densities).

Tracheotomy in Bulbar Poliomyelitis. — According to Priest and his associates, during the 1946 epidemic of poliomyelitis in Minneapolis 400 cases were diagnosed as the bulbar type. In 75 of these tracheotomy was performed, and 29 patients survived. At some of the hospitals tracheotomy was done when the following indications existed: respiratory distress as evidenced by recurrent cyanosis, coarse rales in the chest and laryngeal stridor; excitement and unmanageability, causing the patient to resist pharyngeal aspiration; stupor of a degree sufficient to make the patient oblivious of the accumulation of secretion in his airway; inability to cough effectively; pharyngeal pooling of mucus; vocal cord paralysis, or intralaryngeal hypesthesia demonstrable by laryngoscopic examination. Physicians in charge of the adult neurology service came to believe that tracheotomy gave the patient his best chance if it was performed before cyanosis occurred, because cyanosis can only be diagnosed clinically when it is rather far advanced and when anoxia has caused irreversible damage to a central nervous system already damaged by the virus. The authors conclude that tracheotomy improves the chance for survival of properly selected patients, and that tracheotomy used in conjunction with various means for producing artificial respiration will enable some patients who are critically ill with poliomyelitis to survive.

Poliomyelitis in Relation to Tonsillectomy.—Pedersen reviews material from the files of the San Francisco City and County Hospital and the Children's Hospital of the same city. All facilities for hospitalization of poliomyelitis patients in the city of San Francisco are in the contagion wards of these two hospitals. The incidence of poliomyelitis to the general population in the epidemic year 1943 was in a ratio of 1 to 1,960, while the incidence of poliomyelitis after tonsillectomy for the same period was in a ratio of 1 to 1,782. The incidence of poliomyelitis following recent tonsillectomy is not greatly out of proportion to the ratio of disease to the general population during an epidemic year. However, there is a higher incidence of bulbar and bulbospinal type poliomyelitis in tonsillectomized patients than in nontonsillectomized patients, the ratio being 2 to 1.

Thyroid and Nose.—Proetz states that certain indolent and intractable nasal conditions are peculiar to the type of person regarded as hypothyroid. He concludes from a survey of 84 cases that deficiency of the thyroid hormone may result in two types of changes in the nasal mucosa: (1) red, dry, irritated, "chapped" or desquamative; (2) pale and boggy. Patients deficient in the thyroid hormone may have an increased tendency to nasal infection and nasal allergy, which can be corrected by the administration of thyroid extract alone. Headache and nasal obstruction are prominent symptoms. The basal metabolic rate is helpful but not infallible in distinguishing cases suitable for treatment with thyroid extract.

Present Status of Diphtheria.—Place thinks that the present interest in diphtheria is probably due to fear of spread of a new virulent type for which antitoxin is more or less ineffectual and conditioned by a prior idea that diphtheria had been quelled. Neither of these ideas is entirely true. Place cites figures on the diphtheria mortality in Boston, Europe and Great Britain to point out that, although fluctuation of the virulence of diphtheria occurs, it is not associated with the development or introduction of a peculiar, fixed strain. The apparent ineffectuality of antitoxin is more likely to be related to the time of treatment and the speed of the toxin's action. If antitoxin is delayed more than twenty-four hours after the onset of the infection some deaths occur, and the percentage death rate rises rapidly with each day's additional delay. The conception of antitoxic immunity to diphtheria in Schick-negative persons has often been too dogmatic. Immunity is relative, and it is impossible to set the level of immunity that will protect under all conceivable conditions of infection and virulence. Immunization with two doses of alum-precipitated toxoid or aluminum hydrate absorbed toxoid at intervals of three weeks to three months or three doses of soluble toxoid every three to six weeks is satisfactory. Booster or recall doses of toxoid every three to five years are considered desirable although not yet proved essential. Children should be given toxoid or a similar antigen preferably between the sixth and eighth months of age. For treatment, despeciated antitoxin treated chemically and with pepsin-hydrochloric acid or a similar digestant has a great advantage, being low in bulk and largely free from protein reactions as compared to the high percentage of reactions from crude antitoxin. Sulfonamide compounds and penicillin have had no effect on the treatment of diphtheria but are of value in reducing the dangers from secondary infections. Penicillin has proved to be the best therapeutic agent available for the carrier state.

Vascular Effects of Curare in Man.—Grob and his associates found that intracutaneous administration of curare and of *d*-tubocurarine chloride to human subjects produced a local flare and wheal with pseudopods. Intra-arterial administration of the drug produced weakness, discoloration, swelling and wheals of the injected forearm and hand; evidence of local and general vasodilatation, and increased secretion of gastric acid. Intravenous and intramuscular administration produced no evident swelling or wheals and less peripheral vasodilatation and secretion of gastric acid. The intracutaneous and intra-arterial administration of histamine produced vascular effects similar to those of curare. The local and general vascular effects of curare were inhibited by the prior or simultaneous administration of the antihistaminic drug, "pyribenzamine" (tripelennamine hydrochloride). The vascular effects of curare suggests that the intra-arterial administration of this drug causes the release of a histamine-like substance which acts first locally and then systemically. This substance apparently also is released after intracutaneous administration of curare and to a lesser degree after intramuscular and slow intravenous injection. The release of a histamine-like substance following the administration of curare may explain the occurrence during curarization of vascular and other phenomena which resemble the effects of histamine. "Pyribenzamine" may prove to be of value in the prevention and treatment of these histamine-like actions of curare.

Hyperventilation Syndrome in Gastroenterology.—McKell and Sullivan found that in 500 consecutive ambulatory patients with gastrointestinal complaints hyperventilation was recognized 29 times, an incidence of 5.8 per cent. One of the commonest symptoms of hyperventilation is dizziness. Other common symptoms are air hunger, sensation of tingling or numbness, palpitation and precordial or substernal pain. The most important basis for the production of the syndrome appears to be chronic anxiety. Abdominal symptoms are frequently the mechanism by which attacks are initiated. The attacks often occur so frequently that a conditioned reflex is established, which may be reproduced by any of various stimuli originally present. Recognition and demonstration of the hyperventilation syndrome to the patient are frequently the key to the management of a baffling clinical problem.

Homologous Serum Hepatitis.—Rosenthal observed during a ten month period 4 instances of probable homologous serum hepatitis on the gastrointestinal service of the Graduate Hospital of the University of Pennsylvania. Six hundred and ninety-five units of blood and plasma (including pooled plasma obtained from the Office of Civilian Defense) were administered to 98 patients. The incubation period ranged from fifty-six to ninety-three days. Because of the onset of icterus following the administration of blood and plasma, particularly in the absence of any known exposure to other cases of infectious hepatitis, the jaundice was considered to be due to homologous serum hepatitis. The possibility of the jaundice being due to common infectious hepatitis cannot be excluded. Three patients received blood and plasma; 1 patient received plasma only. No frank jaundice was observed in any patient who had received whole blood exclusively during this period. The symptoms were mild. Therapy consisted in the administration of a high carbohydrate, high protein diet supplemented by the parenteral administration of dextrose and amino acids and the use of vitamin supplements, including vitamin K.

Asthma in the Newborn.—Nance reports 7 cases, which came under his observation and which illustrate the following points: 1. Asthma in the newborn is not uncommon, but is probably the most frequent cause of a wheeze in these infants. 2. It is almost always dietary in origin. 3. Since the diet at this age is extremely limited, the detection of the offending food is simple. The author concludes that the history that an infant wheezed since birth plus the finding of an expiratory wheeze should suggest a probable diagnosis of asthma due to food allergy. Physicians should be unwilling to accept a diagnosis of thymus enlargement as the cause of noisy respiration in the newborn on the basis of roentgen observations alone.

Bone Grafts in Tuberculosis of Joints and in Pott's Disease.—Sorrel and Sorrel-Dejerine evaluate the use of bone grafts for immobilization in the treatment of Pott's disease and tuberculosis of the joints on the basis of their experience with bone grafting. They have gained the impression that among adolescents, adults and aged persons immobilization grafts have been of great help in the treatment of tuberculosis of the joints; and that in two of its most frequent and most severe localizations, in the spine and the hip, end results have been greatly improved by bone grafts. Among children the use of grafts has brought only slight modifications in the treatment of Pott's disease and tuberculosis of the joints. However, in the sequelae of hip disease these immobilization grafts have been found to be extremely useful.

Bone Bank for Homogenous Bone Grafts.—Macewen reported the first successful transplantation of bone from one person to another in 1878, but the use of homogenous bone transplants has received only casual notice. The fate of homogenous bone transplants was uncertain and the preservation and availability of such tissue has been an obstacle. Bush reviews the literature and reports results of bone homografts in 67 operations. He stresses that homogenous bone may be used as a transplant under the same conditions as, or in conjunction with, autogenous bone. The blood type has no influence on the successful use of homogenous grafts of bone, nor does the Rh factor influence the results. Bone may be stored in sealed containers at from 2 to 5 C. for periods up to three weeks. Bone may be preserved in sealed containers in the deep freezer at approximately —25 C. for an indefinite period. Microscopic studies of bone removed from fused areas in which homogenous bone had been used showed the grafts to be dead but surrounded by connective tissue undergoing metaplasia and new-bone formation. The success of homografts of bone has been shown by clinical results, by direct inspection of the fused area and by roentgenographs. Homografts of bone, available in a bone bank, will eliminate a second operation on a normal ilium or tibia, with its possible complications, and will shorten the time of operation and hospitalization.

Absorbable Substances to Obliterate Bone Cavities.—According to Buchman and Blair the treatment of chronic osteomyelitis by saucerization and primary closure of the wound under antibiotic influences has brought with it the problem of control of the hematoma which develops in the resultant bone cavity. The use of intramuscular injections of penicillin before and after the operative procedure and of local applications of penicillin before closure of the operative wound, without drainage, has been found to control infection, provided that the procedure has been sufficiently thorough, until the hematoma becomes adequately organized to resist infection. If the hematoma is too large to be organized rapidly, a sinus results. This reestablishes the cavity and exposes the operative site to reinfection from without, with resultant delay or failure of healing. The authors used absorbable gauze and absorbable gelatin ("gelfoam") in an attempt to fill the bone cavity and to control the continued oozing from the operative site. These substances were left in the wound to be absorbed by the tissues and also served as vehicles for penicillin. In some instances "gelfoam" was used as a partial filler of the cavity in conjunction with thrombin to control the oozing and with penicillin to control the infection. The use of oxidized gauze or absorbable gelatin as a vehicle for thrombin and penicillin in filling dead spaces or bone cavities appeared to be inadvisable because of many complications interfering with the healing of surgical wounds by first intention. The use of oxidized gauze or absorbable gelatin with thrombin as hemostatic agents in the presence of troublesome oozing and bleeding is advisable, and at times invaluable, notwithstanding the fact that the final healing of the wound may be delayed, in a considerable proportion of instances, by temporary partial disruption incidental to the evacuation of collections of blood and serum.

Arthroplasty for Congenital Dislocation of Hip in Children.—Colonna reports end results of an arthroplasty procedure devised some years ago for the treatment of congenital dislocation of the hip. From his follow-up study of ten to thirteen years he arrived at the following conclusions: 1. The two stage procedure in the younger age group is permanently effective in providing accurate reduction, stability and an excellent range of mobility. 2. Careful attention to details is essential not only in the first and second stages of the operation but also in the early part of the postoperative period. 3. The results have been better with the unilateral than with the bilateral dislocation. 4. The procedure is not to be employed in children beyond the age of 10 years; the best results have been obtained in children under 8 years of age.

Plasmacytoma of Hypothalamus.—Plasma cell tumors are usually multiple, occurring in bone. Instances of single plasmacytomas of soft tissue have been reported. Sites most commonly involved are the nasopharynx or conjunctiva. In no instance did the tumor arise primarily in the central nervous system. The case reported by French represents such a primary involvement of the central nervous system, the single lesion being found at necropsy in the hypothalamus. The case was that of a woman aged 42. The microscopic appearance of the hypothalamic mass was quite at variance with that anticipated from gross inspection of the sagittally sectioned brain. The expected glial tumor did not materialize. Infection and hemorrhage clouded the microscopic appearance of the area so that the origin and true nature of the mass was obscured. The neoplastic rather than inflammatory nature of the plasma cell accumulation was indicated by the well localized arrangement of the cells. The site of the tumor was the most unusual aspect of the case. It must be considered as a single extramedullary plasmacytoma and not a metastasis, in view of the absence of other foci.

Fatal Poisoning by Lead Benzine.—Bini and Bollea describe microscopic and histochemical observations in 2 cases of fatal poisoning by tetraethyl lead. The question is raised as to whether tetraethyl lead exerts its lethal action on the nervous system through the metal combined with organic radicals or through its ethylic radical alone. The authors consider that their inability to demonstrate lead in the nervous system of their 2 patients in the presence of a clinical and histologic picture reminiscent of alcohol intoxication, suggests that at least in these cases the cause of the toxic action was not lead but the tetraethylic radical.

Primary Glioblastoma Multiforme of Cerebellum.—Powell states that cross section of a glioblastoma is characterized on gross inspection by a variegated display of colors; numerous areas of degeneration, hemorrhage and, frequently, small cysts; and tremendous edema and distortion, resulting in flattened and pale, sometimes translucent, convolutions. The aptly descriptive name, glioblastoma multiforme, may be appreciated when the tumor is examined microscopically and the confusing series of cellular forms and appearances are revealed. The multiformity of cell type on one hand and the extensive vascular phenomena and areas of necrosis on the other are perhaps the most typical observations. The author reports a verified instance of this tumor arising as a primary and isolated neoplasm of the cerebellum. Only 3 instances of primary glioblastoma multiforme of the cerebellum of reasonable certainty can be found in the literature. Two additional cases are doubtful, 1 because of an incomplete specimen and 1 because of possible misinterpretation of direct tumor extension into adjacent areas. Seven other cases are included as possible instances, although each is considered improbable. Thus primary glioblastoma multiforme of the cerebellum appears to be a rarity. The significance of the fact that this most commonly observed form of glioma does not appear in the cerebellum is unknown.

Roentgen Therapy in Arthritis and Bursitis.—Pohle and Morton employed roentgen radiation in the treatment of 100 patients with osteoarthritis and 69 patients with bursitis in the department of radiology, state of Wisconsin General Hospital. Most patients received one series of treatments, but about 40 per cent had two series and a small number three. Satisfactory relief from pain was obtained in approximately 74 patients with osteoarthritis; the corresponding figure for bursitis was 57. No theory as to the mechanism of the therapeutic effect is offered; it may be based on a nonspecific analgesic action of the roentgen rays.

Appendical Coproliths.—Thomas reports the occurrence of appendical coproliths in 6 patients between the ages of 6 and 56 years. Hypertrophy of the muscle wall of the appendix was observed in 5 of the cases. This may be the mechanism of the intermittent colic, the history of which can be elicited after the presence of the calculus is discovered. The amount of calcium and the degree of hardness of the calculus depend on the age of the fecalith. One of the four largest coproliths yet reported, 3 by 1.5 cm., is included in this small series. When the diagnosis of "chronic appendicitis" is entertained, a roentgenogram of the abdomen with the patient supine should be made to rule out the possibility of a calcified appendical coprolith. The diagnosis of chronic appendicitis is impossible roentgenographically. It is only inferred that when a clearcut history fits with roentgenographic diagnosis of an appendical coprolith, intervention for chronic, recurring appendicitis will yield benefits.

British Journal of Ophthalmology, London

31:449-516 (Aug.) 1947

*Effect of Aluminum and Its Alloys on Eye. L. H. Savin.—p. 449.

Effect of Aluminum and Its Alloys on the Eye.—Savin reports a case in which a piece of aluminum zinc was observed over a period of three years as it lay on the retina of an only eye. The metal was at first bright and silvery. Later it became coated with a white cover probably of aluminum hydroxide. The fragment shifted twice, each time leaving a retinal imprint, before it eventually disintegrated into white powder. In a second case the metal behaved similarly. Twenty-five implantations of aluminum and aluminum alloy fragments were made into the anterior chambers of the eyes of rabbits and 9 into the vitreous chambers. General effects on the eye included lens opacities, striae, dots, vacuoles and irregular opacities. Inflammatory changes in the uveal tract were frequent. Other changes included fundus pigmentation, localized choroiditis and retinitis proliferans. On the basis of clinical and experimental evidence it is concluded that the eye is by no means inert to aluminum.

Treatment of Abortion.—Corston and Stallworthy instituted an interventionist attitude in cases of inevitable and incomplete abortion. After the vulva and vagina had been swabbed, the surgeon examined the pelvis to determine the position of the uterus and the state of the cervix in order to avoid perforation by dilators or forceps. If the canal was patulous and placental tissue was in reach it was removed. If not, the cervix was exposed and an oxytocic drug was injected under vision into the cleaned cervix. Unless it was already patulous the cervical canal was dilated to the size of a no. 14 or 16 Hegar dilator. Sponge forceps were introduced, opened, rotated through 90 degrees, closed and withdrawn. This was repeated until no further pieces of placental tissue were removed. Then the cavity was explored with a flushing curet and packed with a sterile gauze roll, which was removed six hours later. In septic cases this pack was impregnated with sulfathiazole powder. This method has been employed in 600 cases of abortion, in 42 of which there was infection on admission. In the cases with infection chemotherapy was started before the uterus was evacuated. There was 1 death in this series. The authors conclude that surgical evacuation of the uterus, if carefully performed, is safe and efficient. The length of stay in the hospital is reduced by this method. The low mortality is attributed to the fact that a team skilled in handling these cases was responsible for them.

Vagal Resection in Treatment of Duodenal Ulcer.—According to Orr and Johnson the incidence of chronic and recurrent ulceration is increasing and presents a serious problem. Although 80 per cent of ulcers can be healed medically, 65 per cent of the patients have a recurrence within two years. The risk of complications is considerable, since 1 in 4 or 5 patients have serious hemorrhage or perforation while still young. Gastrojejunostomy is a failure as a routine procedure. It carries a mortality of about 2 per cent and does not cure more than half of the patients. Gastrectomy is more successful if it is sufficiently radical, but it is also more dangerous. The operative mortality may be 5 per cent and the recurrent ulceration rate from 2 to 9 per cent. A further percentage is not freed from symptoms and new symptoms may result from the operation itself. Incomplete vagal resection gives poor results. The insulin test is helpful in differentiating complete from partial vagotomies. The authors have done fifty vagotomies or vagal resections in the last two years without a death. The long term results of vagal resection are not yet known, but little is lost if, on occasion, it fails, for a gastrectomy is still possible. A lasting success by vagal resection is a triumph of physiologic strategy, and failure does not spell disaster.

Clinical Thermometers as Source of Cross Infection.—Green and Penfold outline the procedures usually employed in taking temperatures in hospital wards and show that these procedures not only are unsound but may be dangerous. The thermometers remain in the sterilizing fluid only a few seconds between one patient and the next. While some antiseptics are bactericidal in a few seconds, these would almost certainly be harmful to the mucosa of the mouth. The use of inefficient antiseptics gives a false feeling of security. The authors suggest that each patient be supplied with a thermometer which he keeps to himself as long as he stays in the hospital. It can be left by the patient's bed in a small jar containing an antiseptic solution. When the patient leaves the hospital, this thermometer must be properly sterilized before being used again. This can be done by washing the thermometer in running cold water, drying it and placing it long enough in some effective antiseptic.

Comparison of Ointment "Aerosol 5" with Number 5 Against Lewisite. E. R. Trethewie.—p. 785.

Dental Defects in Infants After Maternal Rubella.—Of 67 children born to mothers who had rubella during pregnancy, 30 exhibited congenital dental abnormalities, in 20 cases major in degree. Caries was disregarded in this calculation. If caries and restricted arch formation are taken into account, the abnormalities are detectable in 46 of the children. With the exception of 5, the remainder of the infants show other concongenital malformation. The main abnormalities occurred in the children of mothers who had contracted rubella during the first three months of pregnancy; in the "later pregnancy" group the abnormalities were few in number and minor in degree. The main dental abnormalities comprised retardation of eruption, dental caries and hypoplasia of enamel. Three cases of congenital absence of isolated deciduous teeth and 4 of premature eruption of permanent teeth are recorded.

Management of Tuberculous Empyema. A. J. Coello.—p. 136.
Cavitation in Pulmonary Tuberculosis. R. Grenville-Mathers.—p. 139.
Particular Type of Tuberculous Pulmonary Cavitation Tending to Spontaneous Healing. L. Dunner.—p. 144.

Survival of Sputum-Positive Consumptives.—The material reviewed by Tattersall comprises 1,192 patients with positive sputum that were given diagnosis between 1914 and 1940. Five per cent of the patients were lost sight of. No difference in prognosis in respect of age or sex is disclosed for adults, but adolescent males are found to have better prospects of survival than adolescent females. No difference in survival is proved for successive quinquennial periods. In 32 per cent of the standard 1,000 cases patients survive five years. In 22 per cent they survive ten years. After a five year survival there is a 50:50 chance of surviving a further fifteen years. After ten years, there is a *2:1* chance of surviving a further ten years. Differences in the survival of patients experiencing treatment in sanatoriums and patients not doing so appear to be transient only. The clinical features for patients surviving longest show no consistent resemblance to one another.

Diagnosis of Ectopic Pregnancy by Hysterosalpingography. B. Nielsen.—p. 185.

Changes in the Lungs in Asbestosis.—Wegelius describes observations on 126 cases of asbestosis among 476 workers of the Finska Mineral Company. The patients presented roentgenologic signs of asbestosis; 94 had a mild form, 23 a moderate form and 9 an advanced form of the disease. The roentgenologic changes in the lung are the most important diagnostic criteria. Various stages of asbestosis can be differentiated roentgenologically. In the classification of his material Wegelius followed Saupe's rather than Shull's method. Uncomplicated cases of pure asbestosis usually corresponded to stages 1 and 2. Moderately severe cases with emphysema and thickening of the pleura and pericardium were extremely common, and the roentgenographic changes were usually those of stages 2 and 3. Cardiac enlargement was less frequent in the author's material than the literature indicates. The rather high percentage of advanced cases (compared with statistics from other countries) is probably due to the fact that this industrial disease has only rather recently been given the attention it deserves. Now that careful supervision is exercised the high figures for more advanced stages will presumably be reduced.

Preoperative Roentgen Treatment in Cancer of the Breast.—Kaae evaluates the results obtained at the Radium Center in Copenhagen in 301 cases of cancer of the breast. Treatment by radical surgical intervention either followed or preceded roentgen therapy. The patients were observed for from two to thirteen years, 137 of them five years or more. Wegelius divides the cases into two groups. Stage 1 comprises those in which cancer was present only in the breast, stage 2 those in which the axillary lymph nodes were involved. The method of roentgen treatment varied. Prior to June 1, 1938 a moderate preoperative treatment was given, supplemented by a lesser postoperative radiation; after that time only a strong preoperative roentgen treatment was given. Preoperative irradiation seems to improve the results. The frequency of distant metastases was the same in the preoperatively and the postoperatively irradiated group, whereas the frequency of local recurrence was so much greater in the postoperatively treated patients that it may perhaps explain the better results in the preoperatively treated group.

Significance of Perforation of Bronchus in Tuberculosis of Endothoracic *Lymph Nodes.* O. Görgényi-Göttche and D. Kassay.—p. 311.

Penicillin in Influenzal Meningitis Empyema and Osteomyelitis—Hirsch and Nassau used penicillin treatment in 3 cases of meningitis, 2 of empyema and 1 of osteomyelitis, all caused by influenza bacilli and all affecting young children. The treatment with penicillin was successful. The authors suggest the following general directives for the treatment of purulent infections caused by strains of influenza bacilli sensitive to penicillin. Whenever suppurating meningitis, pleural empyema or osteomyelitis develops in a young child or nursling, penicillin should at once be given intraspinally or into the pleura or muscle until the type of pathogenic organism and its sensitivity to penicillin has been established. The results of these tests determine whether penicillin therapy should be continued. Hirsch and Nassau found that in empyema and in osteomyelitis treatment with penicillin was adequate, provided it was administered in sufficiently large doses. The combined administration of penicillin and sulfadiazine appears to be the method of choice in treatment of influenzal meningitis.

*Acute Barium Poisoning. R. Gilli.—p. 24.

Acute Barium Poisoning.—Acute poisoning with barium is rare. One hundred and forty-two cases are reported in the literature. Gilli reports the case of a woman aged 28 who was given erroneously a solution containing 30 Gm. of barium chloride instead of sodium sulfate. The patient took only half of the dose when she manifested symptoms of acute poisoning, abdominal cramps and vomiting followed by paralysis and asphyxia. Lavage of the stomach, hypodermic injection of 1 mg. of atropine sulfate, lobeline and other measures failed. Death occurred within nineteen hours. The author observed at necropsy two lesions of medicolegal value in the anatomicopathologic diagnosis of barium poisoning, namely, lesions of the nerve cells of the brain and brown granulations in the renal tubules, the seat of acute lesions.

*Macrocytic and Megalocytic Anemia in Hunger Edema. E. Koch and P. Lübbers.—p. 254.
Improved Method of Percutaneous Arteriography. Brobeil.—p. 257.

Macrocytic and Megalocytic Anemia in Presence of Edema.—Koch and Lübbers discuss the special forms of anemia that appear in the presence of hunger edema on the basis of observations on 15 cases. The anemias were usually hyperchromic, macrocytic and nonhemolytic (13 cases). In 12 patients the anemia was megalocytic, that is, it resulted from a disturbance in the regeneration of the erythrocytes and was accompanied by increased hemolysis. In both forms Castle's intrinsic factor was demonstrable in the gastric juice, and both forms were characterized by their rapid reaction to liver extracts and autolyzed yeast. The authors think that the etiologic factor is a food deficiency, probably of the vitamin B_2 complex.

Performance Tests in Evaluation of Patients with Silicosis. F. Lang.—p. 257.
*Sedimentation Rate of Erythrocytes and Tuberculosis. P. M. Steiner.—p. 297.

Tuberculous Endocarditis and Congenital Pulmonary Tuberculosis.—Aufdermaur describes the occurrence of late pulmonary primary infection with transition into general miliary tuberculosis and tuberculous endocarditis of the chordae tendineae of the tricuspid valve and tuberculous endometritis in a woman aged 26. Hematogenous tuberculosis developed during pregnancy. The infant died on the twenty-fifth day of life as the result of a disseminated primary tuberculosis of the lungs, which resulted from aspiration of amniotic fluid containing bacilli. The author discusses the pathogenesis of tuberculous endocarditis and thromboarteritis and compares the evolution of primary infection in mother and child.

Erythrocyte Sedimentation and Tuberculosis.—Steiner shows that, if the sedimentation speed of the erythrocytes is determined with an exact technic and at carefully chosen times and intervals, the plotted curve of the sedimentation rate permits conclusions with regard to diagnosis and prognosis, and it may be a guide to the proper treatment.

Book Notices

Cancer: Diagnosis, Treatment, and Prognosis. By Lauren V. Ackerman, M.D., Pathologist to the Ellis Fischel State Cancer Hospital, Columbia, Mo., and Juan A. del Regato, M.D., Radiotherapist to the Ellis Fischel State Cancer Hospital. Cloth. Price, $20. Pp. 1115, with 715 illustrations. The C. V. Mosby Company, 3207 Washington Blvd., St. Louis 3, 1947.

The first part (one hundred and twenty-five pages) treats of cancer in general. After the introduction comes an excellent review by M. B. Shimkin of the National Cancer Institute of the methods, results and prospects of experimental cancer research. This is followed by chapters on the pathology of cancer and on its treatment. The physics of radiation, its effects on normal tissues and on cancer, the indications for radiotherapy of cancer—the current methods and the clinical control—are described clearly and constructively. The pathologist is reminded that it is now outside his province to decide on the radiosensitivity of cancer on the basis of microscopic structure. While surgical intervention remains the only hope of cure in many forms of cancer, "the day is past when a surgeon can be considered competent simply because he is technically capable of carrying an operation to completion. The cancer surgeon must be pathologist, amateur physicist (and radiotherapist), physiologist and statistician, as well as surgeon and philosopher." With the necessary changes in the words this statement applies also to the radiotherapeutist. It is noteworthy, too, that by cancer research the authors understand "not only laboratory experimentation, but the clinical study of the disease, the constant improvement of the methods of treatment, and the statistical research which this may imply." The book is dominated by the spirit of an advancing cancerology. The other fifteen chapters, some nine hundred and fifty pages, deal with cancer in the different parts of the body except the central nervous system, beginning with cancer of the skin. The chapter on cancer of the respiratory and upper digestive tracts is the longest; next comes that on the rest of the digestive tract, and then that of the female genital tract. Each chapter and subsection follows the same sequence, namely, anatomy, the incidence of cancer and etiology, pathology, clinical evolution, diagnosis, treatment and prognosis. References to articles quoted in the text are listed at the ends of the chapters. The treatment of present choice is indicated in each case but without bias and without details of interest mainly to the trained specialist. The structure of the cancers is clearly described and well illustrated, the naked-eye appearances abundantly so. The number of pictures of cancer of the skin and the lip could be reduced without any loss of clarification of the text. There are seventy-six informative tabulations of significant cancer data of various kinds. Of much interest are the outline sketches of anatomic relations at cancer sites, and especially of the course and distribution of the lymphatics concerned in the metastasis of cancer. The book is well indexed by authors and by subjects. Throughout the book "cancer" is used freely in place of "malignant disease" or "malignant tumor," but "cancerous" could have been used more often than it is in place of "malignant" in the sense of cancerous. One wonders how it happens that a new word, not in our dictionaries, namely "exophytic," is used to describe certain cancers of the lips and elsewhere. Another apparently new word in cancer lingo is "semimalignant," used in discussing mixed tumors of the salivary gland type. The existence of alveolar carcinoma of the lungs is taken for granted without any reference to the claims of anatomists that there are no cells lining the alveolar walls. But these are not important matters of immediate practical significance. The book gives a good, reliable, comprehensive account of the present knowledge of human cancer as a practical problem. It will be of great help to the clinician and the student. The Ellis K. Fischel State Cancer Hospital at Columbia, Mo., may well rejoice that its rich material has been put to such good use by members of its staff in writing a first class textbook on cancer.

Lebendige Gewebelehre: Eine Histophysiologie auf neuer Grundlage. Von Dr. med. et phil. Paul Vonwiller, Assistenzarzt an der kantonalen Heil- und Pflegeanstalt in Rheinau (Kanton Zürich, Schweiz). Paper. Pp. 241, with 26 illustrations. Kommissionsverlag Zollikofer & Co., St. Gallen, 1945.

This monograph was written in Moscow, Russia, in 1938-1939; most of the early work was done with the help of Russian assistants. As the title indicates, the present volume deals with microscopic study of living tissues in contrast to the classical method of fixing, staining and mounting thin sections of dead tissues, to which the author alludes in his introductory chapter. Throughout the monograph the author points out that he and his collaborators studied microscopically only living organs "in vivo et in situ."

The material for study consisted chiefly of anesthetized frogs, rats and rabbits, as well as plants. The method of study with high-powered, specially constructed microscopes allowed even the use of oil immersion lenses on otherwise opaque organs whose blood supply was intact. The details of these instruments as well as the micromanipulators (used over twenty years) will be described in a separate volume.

The organs and tissues chiefly studied "in vivo et in situ" comprise the eye (Gullstrand's slit lamp), skin with its capillaries, lymphatics, thyroid gland, kidney, and, with dyes, the capillary permeability, peripheral nerve and single nerve fiber, the nerve nets of the stomach, the olfactory lobe and nerve, the brain and the movements of the cerebrospinal fluid observed through the covering of the fourth ventricle. Observations of this latter assured him that there occurs a continuous movement of the fluid both cephalad and caudad (a sort of circulation). Injection of dilute methylene blue into the circulation while studying the cells of the thyroid gland revealed only a rather permanent blue coloration of the colloid, whereas the methylene blue in the rest of the tissue of the animal (frog) was rather promptly converted into the leukobase (methylene white).

The book constitutes essentially a résumé of the work on vital microscopy done over the past twenty years by the author and pupils (62 references). Dr. Knisely's work is only casually mentioned twice (pp. 31 and 162) and Markee's work not at all. Neither does the bibliography contain a reference to either of these two American investigators, who have worked in this field for about an equally long period of time.

For much of the data one must refer to the author's original scientific contributions. It would appear that in its present state of development the research referred to in this book will be of interest solely to the anatomist, physiologist and pathologist, even though the author considers the material easily adaptable to clinical studies.

Tuberculosis Hospital Planning and Construction. By J. Bruno Basil. American Trudeau Society, Medical Section. Written under direction of Committee on Sanatorium Planning and Construction, American Trudeau Society. Paper. Price, $1. Pp. 81. National Tuberculosis Association, 1790 Broadway, New York 19, 1946.

In 1943 a Committee on Sanatorium Planning and Construction was formed by the Medical Section of the National Tuberculosis Association to rewrite the Manual on Sanatorium Planning originally prepared in 1929 and revised in 1939. The first phase of the committee's work was concerned with the collection of information on important trends and changes in sanatorium planning that have occurred in recent years in accordance with modern developments in the treatment and care of tuberculosis. This study led to the development of architectural plans for a 200 bed tuberculosis hospital as well as the publication of the present brochure, a correlative volume on tuberculosis hospital planning and construction. The new edition gives information on practically all phases of sanatorium planning, including the development of individual services and departments. It considers the factors involved in the organization of a hospital program, the selection of an appropriate site, the planning of administrative and general services, x-ray and laboratory facilities, medical and surgical needs, types of accommodations, outpatient requirements, dietary department, recreation and rehabilitation, auxiliary facilities, storage, housekeeping, laundry, mechanical services and power, electrical communications and fixtures, quarters for personnel and landscaping of hospital grounds. This book, representing as it does a careful study and analysis of the needs of sanatorium services, will be welcomed by medical and administrative personnel, boards of trustees, architects and all others directly concerned in the planning and organization of hospital facilities essential to the modern care and treatment of tuberculosis.

Pulmonary Tuberculosis: A Handbook for Students and Practitioners. By R. Y. Keers, M.D., M.R.C.P., F.R.F.P.S., Medical Director, Red Cross Sanatoria of Scotland, Tor-na-Dee, Milltimber, Aberdeenshire, Scotland, and B. G. Rigden, M.R.C.S., L.R.C.P., First Assistant Medical Officer, Red Cross Sanatoria of Scotland. With a foreward by F. H. Young, O.B.E., M.D., F.R.C.P., Medical Officer in charge of the Tuberculosis Dispensary, St. Bartholomew's Hospital, London. Second edition. Cloth. Price, 17s 6d. Pp. 277, with 124 illustrations. William Wood & Co., Mount Royal & Guilford Aves., Baltimore 2: E. & S. Livingstone, 16-17 Teviot Place, Edinburgh 1, 1946.

Although this is about the same size as the first edition, deletions have been made and replaced by new material. This handbook is intended primarily for students and practitioners of medicine. The first chapter consists of a historical sketch of the development of our knowledge of tuberculosis, followed by a chapter on bacteriology in which the tubercle bacillus is presented with reference to types, staining, culture and inoculation methods. Considerable space is devoted to an excellent presentation of the pathology of tuberculosis. Here all the important steps from the development of the primary lesion to fatal, acute and chronic forms of tuberculosis are presented.

Some controversial points are discussed under the subject of epidemiology and resistance in chapter four, for example the statement that greater resistance is present among those who react to tuberculin than among nonreactors. A number of workers will take issue with this statement and point out that the human body never tolerates tubercle bacilli as well as it does at the time of the initial infection. The statement to the effect that relatively few persons infected with tubercle bacilli contract clinical disease may be challenged by such persons as Bogen, who, in an article on "The Toll of Tuberculous Infection" concluded that as many as 50 per cent of infected persons may at some time have clinical lesions (*Am. Rev. Tuberc.* **42**:253 [Aug.] 1940).

The tuberculosis situation differs considerably from country to country and even in various parts of the same country. For example, under the heading Incidence of Infection attention is called to the high percentage of tuberculin reactors among children of such cities as London and Glasgow. Fifty-eight per cent of children between 10 and 15 years of age are infected in London and 45 per cent in Glasgow. This is in sharp contrast to the findings in cities of the United States, such as New York and Chicago, where the incidence of infection among high school students does not exceed 20 per cent, and in smaller cities from 6 to 15 per cent. As morbidity and mortality rates run parallel but on a lower level than the infection rate, one finds the lower morbidity and mortality in parts of the world where the infection rate is low.

The authors point out that there is no difference in the forms of pulmonary disease caused by the bovine and human types of tubercle bacilli, although the human type is responsible for the great majority of pulmonary lesions. Therefore it is felt that there is no great dissimilarity in the degree of virulence between the bovine and the human types of bacilli for human tissues.

Various diagnostic procedures are presented in a concise and clear manner. The authors state that "it is by virtue of its power in provoking the hypersensitive reaction in the infected body that tuberculin, by demonstrating that primary infection has occurred, is of such great value in diagnosis and in mass investigations." Chapter eight contains an excellent presentation of differential diagnosis. All the modern therapeutic procedures, including the more recent developments in chemotherapy, are presented.

The after-care and rehabilitation of tuberculous patients are given proper consideration. The final chapter consists of a discussion of tuberculosis as a national problem, and some valuable suggestions are offered for its solution.

1946-1947 The Hospital Purchasing File. Established 1919 as the Hospital Yearbook by the Modern Hospital Publishing Co., Inc. Twenty-fourth edition Boards. Various pagination. Purchasing Files, Inc., 919 N. Michigan Ave., Chicago 11, 1946.

This book, which is now in its twenty-fourth edition, continues as an excellent source of information and reference on hospital products and buying. It has an alphabetical list of manufacturers and distributors, a directory of 198 pages on hospital equipment and supplies, and a group of twenty-one manufacturers' catalogues covering administrative, dietary and housekeeping departments, laundry, building construction, maintenance and repair materials, plant operating equipment, professional services and facilities relating to surgery, obstetrics, anesthesiology, radiology, pathology, pharmacy, occupational therapy and physical therapy. Included also are special articles and plans with reference to administrative units, maintenance shops, boiler rooms, surgical units, central supply sections and the hospital pharmacy. The value of the book is further enhanced by an extensive check list of hospital equipment, directories of hospital associations, federal and other agencies serving the hospital and allied fields and the lists and references that have been included in relation to technical schools. As in previous years, this volume provides a vast amount of information of special interest to hospital executives and other personnel concerned in administrative functions of the hospital field.

Hospitals: Integrated Design. By Isadore Rosenfield. Progressive Architecture Library. Cloth. Price, $10.75. Pp. 308, with 264 illustrations. Reinhold Publishing Corporation, 330 W. 42d St., New York 18, 1947.

This book is based on lectures on hospital planning given under the joint auspices of the New York chapter of the American Institute of Architects and the Department of Public Works of New York City. It contains nineteen richly illustrated chapters giving a wealth of information on practically all phases of hospital planning and construction. There is an initial discussion of hospital needs as well as the integration of hospital services in a fully coordinated community plan. Then follow the general considerations of location, site, orientation, architectural planning and detailed analyses of individual departments, supplemented by numerous floor plans and other illustrative material. Careful consideration has been given to nursing units, diagnostic and therapeutic facilities, x-ray and laboratory services, surgical, obstetric and pediatric departments, outpatient requirements, administrative units and other service departments. Sections have also been included on hospital construction and costs, daylighting and artificial illumination, housing and training facilities, special hospitals and hospitals of limited size. The author with his wide experience in the field of hospital planning has presented a book that will be welcomed by all who are interested in the future planning and development of hospital facilities and services.

A Textbook on the Nursing and Diseases of Sick Children for Nurses. By various authors. Edited by Alan Moncrieff, M.D., F.R.C.P., Nuffield Professor of Child Health, University of London, London. Fourth edition. Cloth. Price, 30s. Pp. 744, with 154 illustrations. H. K. Lewis & Co., Ltd., 136 Gower St., London, W. C. 1, 1947.

The first part of this book discusses the general nursing care of the well and the sick child, together with several chapters devoted to general surgical nursing. The second part consists of a presentation of the diseases of children. One is amazed at the amount of information that has been gathered into this volume. There are no wasted words. Its clarity commends it to the nurse as a textbook during her period of training, and its completeness makes it a valuable work of reference when she has begun active work in her profession.

Bacteria in Relation to Domestic Science. By C. E. Dukes, M.D., M.Sc., D.P.H. Cloth. Price, $3.75. Pp. 240, with 10 illustrations. Oxford University Press, 114 5th Ave., New York 11; Amen House, Warwick Sq., London, E. C. 4, 1947.

The author has done a commendable job in presenting bacteriology in an interesting form to the student of domestic science. The activities of bacteria which are related to home life and especially to food are well covered. This book can be recommended for bacteriology courses in domestic science.

Queries and Minor Notes

The answers here published have been prepared by competent authorities. They do not, however, represent the opinions of any official bodies unless specifically stated in the reply. Anonymous communications and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted on request.

TREATMENT OF SCARLET FEVER

To the Editor:—What is the present day method of treating scarlet fever?

M.D., New York.

Answer.—Convalescent scarlet fever serum, scarlet fever antitoxin or penicillin may be used for the treatment of scarlet fever. The sulfonamides are probably not helpful in combating the toxemia of the disease. Nevertheless these drugs are of distinct value when complications develop, although it is doubtful that they prevent complications when used as a prophylactic.

Human convalescent scarlet fever is not plentiful now and therefore often difficult to obtain. Scarlet fever antitoxin may be secured from almost any drug store and is indicated particularly in overcoming the toxemia of scarlet fever but is seldom used to treat complications.

Although there does not seem to be any doubt that penicillin is an efficient remedy in the therapy of scarlet fever, its customary method of administration by intramuscular injection is a disadvantage in adopting it for general usage.

Bed rest for at least one week and an adequate amount of fluids are measures that should not be neglected.

Scarlet fever at the present time is a mild disease in this country.

LIVER FAILURE

To the Editor:—There is a tendency today to relate yellow atrophy of the liver to acute infectious hepatitis. I am referring to acute yellow atrophy attributed to arsphenamine and cinchophen. How does yellow atrophy which is observed now and then in pregnancy fit in this picture?

M.D., Ohio.

Answer.—The prevailing opinion regarding yellow atrophy of the liver is that it represents one variety of acute liver failure. From a clinical point of view it is a poor term because fatal acute liver failure may occur without much decrease in the liver size. Acute yellow atrophy may be produced by a massive insult from a single etiologic factor such as the virus of viral hepatitis or some hepatotoxin such as carbon tetrachloride or arsenic or, what is perhaps more common, it may be the result of several etiologic factors having a cumulative effect.

In the case of arsphenamine jaundice there is the toxic effect of arsenic, the frequently present syphilitic hepatitis, and usually a superimposed infection with viral hepatitis. Yellow atrophy from cinchophen is probably due solely to the toxic effect of the drug. It is probable that pregnancy imposes some sort of strain on the liver. This may well be of a nutritional nature caused by a deficiency in methionine and related substances. Decreased intake and increased demand for proteins are often present. Such a liver is more vulnerable to viral hepatitis or other liver trauma and can explain the relatively high mortality reported in pregnancy. In addition, eclampsia may be associated with acute liver failure.

CONCENTRATION OF SULFONAMIDES IN BLOOD AND URINE

To the Editor:—It is often difficult to obtain blood samples by venipuncture from infants and young children for various laboratory determinations. However, urine specimens are readily obtained. Is there a definite correlation between urine and blood sulfonamide levels, and can the latter be calculated from the former, assuming unimpaired renal function?

M.D., New Jersey.

Answer.—The discrepancies between the concentrations of sulfonamides in the blood and the urine are sufficiently great to make it an unpractical clinical procedure to ascertain the level of the sulfonamide in the blood by determining the concentration in the urine. Furthermore, the concentration of a sulfonamide in the urine is dependent on the urine volume, and some difficulty is encountered in quantitating the total volume of urine excreted by infants. Then too the proportion of free sulfonamide to acetylated sulfonamide varies from one person to another. A more practical method for determining the blood sulfonamide level in infants and children would be to employ the micromethod, in which only a few drops of blood are necessary.

RADIUM IN THE NASOPHARYNX

To the Editor:—Please give me the present status of the use of radium in the nasopharynx in the treatment of chronic nasal allergy and frequent upper respiratory tract infections complicated by severe deafness. Both of these conditions were present in 2 siblings aged 6 years and 4 years. Both have had complete tonsillectomy and adenoidectomy; but over a one and one-half year period have become progressively worse, particularly as far as their hearing is concerned. Can you suggest any other acceptable form of treatment? It is worthy of note that while there is a strong family history of allergy, there is no history of otosclerosis.

M.D., Phoenix, Ariz.

Answer.—The use of radium in the nasopharynx in the treatment of frequent upper respiratory tract infections complicated by severe deafness is a procedure of the greatest value. First suggested and popularized by Samuel J. Crowe and his co-workers at Johns Hopkins Hospital eighteen years ago, the method is now generally used and approved, as attested by a large number of favorable reports in the medical literature.

Since adenoids form an integral part of the mucous membrane of the nasopharynx they cannot be completely removed surgically, and nodules which are left hypertrophy quickly. Because of their location, these lymphoid masses, particularly when swollen as the result of infection, block the eustachian tubes. Changes in the middle ear and deafness follow.

Before one uses radium in the nasopharynx, there should be sufficient indication to warrant the procedure. The nasopharynx should be visualized through the nasopharyngoscope to see if the tubal orifices are encroached on or occluded by lymphoid masses. Examination of the ears should show some discoloration of the tympanic membrane and retraction, which may be confined to Shrapnell's area. As pointed out by Crowe, audiograms in these early cases may show only a loss of hearing for the higher frequencies, but, as the condition progresses, successively lower tones are involved until the conversational range is reached.

Various investigators have noted that some children who were being treated for deafness and who were also asthmatic showed a concomitant improvement in their asthmatic condition during radium therapy. This has been particularly true in cases due to bacterial allergy, while the atopic conditions have been less benefited. There have not been reports as to the effect on children with chronic nasal allergy, though presumably, if this is due to a bacterial allergy and the bacteria are in infected nasopharyngeal lymphoid nodules, improvement might also be expected here.

HISTOPLASMOSIS

To the Editor:—The following information regarding histoplasmosis would be appreciated: 1. Has any drug been found to be of benefit other than symptomatically? 2. If not, what drugs have been found to be of no value? 3. How effective is the skin test in confirming the diagnosis? 4. Where can the antigen be obtained for this test or the serum be sent for testing?

M.D., Michigan.

Answer.—1. No drug has been found to be consistently beneficial in the treatment of histoplasmosis. Parsons and Zarafonetis (Histoplasmosis in Man, *Arch. Int. Med.* **75:**1 [Jan.] 1945) cited a report of apparent chemotherapeutic success obtained by the use of neostam (stibamine glucoside) in 1 patient with this disease. Another patient apparently derived benefit from treatment with neostibosan (diethylamine para-aminophenylstibimate) alternated with stilbamidine (4-4 diamidinostilbene). These same compounds, however, have failed to alter the course of the disease in other patients. A somewhat similar situation exists with regard to the sulfonamide compounds. These have been unsuccessful in several cases, but A. C. Curtis and E. P. Cawley (article to be published) describe healing of a localized genital lesion following the prolonged use (eighty-seven days) of sulfadiazine 4 Gm. daily.

2. Substances found to be of no value include potassium arsenite, neoarsephenamine, sulfarsphenamine, acetarsone, sodium thiosulfate, iodides, ionized metals, ammonium and potassium tartrate, stibophen, quinine, quinacrine hydrochloride, thymol, bone marrow and pentnucleotide. Several trials of penicillin therapy have also been unsuccessful. Reports concerning the clinical use of streptomycin for histoplasmosis have not yet appeared. Seabury and Artis (*Proc. Soc. Exper. Biol. & Med.* **61:**15 [Jan.] 1946), however, have performed in vitro studies which revealed that high concentrations of this antibiotic did not inhibit the growth of Histoplasma capsulatum organisms.

3. At present the skin test with histoplasmin antigens is of questionable diagnostic value. Several patients with proved histoplasmosis have had negative skin tests. Furthermore, large scale epidemiologic studies such as those of Palmer (*Pub. Health Rep.* **61:**475 [April 5] 1946) have revealed a sur-

prisingly high incidence of positive reactors to histoplasmin. This finding has lessened the possible clinical significance of a positive skin test in a particular individual. In addition it should be recognized that histoplasmin antigens have not been standardized, that the relative value of antigens prepared from the yeast phase and from the mycelial phase of H. capsulatum is unknown and that the significance of cross reactions obtained with other mycotic infections has not been defined. Much work remains to be done before the skin test can be properly evaluated either as an adjunct for epidemiologic surveys or as an ancillary aid in the clinical diagnosis of histoplasmosis.

4. Histoplasmin antigen is not commercially available at present. U. S. Public Health Service workers are actively engaged in histoplasmosis research and may be able to supply the desired antigen. It is suggested that a request be addressed to Dr. Michael L. Furcolow, Field Studies Section, Tuberculosis Control Division at the University of Kansas Hospital, Kansas City, Kansas.

Satisfactory serologic tests for histoplasmosis have not yet been devised.

STATE MEDICINE, SOCIALIZED MEDICINE AND PUBLIC HEALTH

To the Editor:—What is the definition of state medicine?

Scott D. Gleeten, M.D., Monrovia, Calif.

Answer.—The terms "state medicine," "socialized medicine," "public health" and "sickness insurance" are often used interchangeably. Actually there are distinctions which should be kept in mind.

Socialized medicine is an all inclusive term and connotes a form of medical practice in which the method of distributing medical care is made subject to the uses or influences of groups of persons, the community or the state.

State medicine is a form of socialized medicine in which the state attempts to provide medical services directly to the general population from funds raised by taxation. The end result is that physicians become employees of the state, with medical practice subject to the directives of a third party. Any form of state medicine necessarily embodies the use of compulsion.

Public health is a form of socialized medicine concerned with special groups and special activities for the protection of the health of the people as a whole.

Sickness insurance is a form of socialized medicine, either voluntary or compulsory, concerned only with spreading the cost of medical care.

ECZEMA WITH MONILIA ALBICANS

To the Editor:—What is the best treatment for eczema (chronic and subacute) which is caused by Monilia albicans? It appears in the spring and in the fall and covers the hands and feet. What, if anything, can be done to prevent its becoming active during the times when it is quiescent? What is the best treatment if it appears in the mouth?

Kamal Zody, M.D., Tripoli, Lebanon, Syria.

Answer.—The meager description of the condition makes it impossible to arrive at a diagnosis. Monilia albicans is an invader of moist warm areas and therefore produces intertrigo in the large and small folds of the body. For the same reason it is most active in hot humid midsummer weather rather than in the spring and fall. The organism is the most resistant of all the fungi to the fungistatic and fungicidal chemicals which are usually cutaneous irritants and which should be used with great care. Mention is not made as to whether Monilia albicans was found on culture of the tissue. Potassium permanganate soaks in 1 : 4,000 solution and gentian violet in 3 per cent aqueous solution would be safe and probably fairly effective treatment.

A recurrent semiannular eruption on the hands and feet would suggest a seasonal contact dermatitis or a toxic eruption.

COLORED RINGS IN TESTS FOR URINARY ALBUMIN

To the Editor:—I use Robert's reagent in testing for albumin in the urine. The reagent is composed of chemically pure nitric acid 1 part and saturated solution of magnesium sulfate 5 parts. Frequently in making ring tests which are negative for albumin there appears a ring of crimson-violet (as nearly as I can describe it). I have been unable to determine what substance or substances produce this color show and would appreciate it if you could enligthen me.

Seth W. Ellis, M.D., Anderson, Ind.

Answer.—Colored rings near the junction of the fluids may be produced by iodides, urinary pigments, bile or indican, according to Todd and Sanford (Clinical Diagnosis by Laboratory Methods: A Working Manual of Clinical Pathology, ed. 10, Philadelphia, W. B. Saunders Company, 1943, p. 92).

REFRACTORY ECZEMA IN YOUNG WOMAN

To the Editor:—A married woman aged 34 developed an eczematous eruption on the hands during adolescence which has been with her most of the time since. It was treated as an eczema with varying degrees of success, but she was rarely free from discomfort until during her first pregnancy, when the eruption disappeared spontaneously and she was free from it till some months advanced in lactation. This occurred during each of her three pregnancies. Each time the relief was shorter after confinement. During the years before marriage there had been plenty of evidence that the condition was affected by diet and she was restricted after taking tests and experimentation with diets almost to the point of starvation. During the periods of pregnancy she could eat freely and without any restriction whatever. Between the second and third pregnancies antuitrin-S was found to give nearly complete relief for over two years. It was used steadily a short time and then just before menstruation. The beneficial effect of the antuitrin seems to have worn off, and now with the last baby eight months old and menstruation not well establihsed she is having continuous misery. A diagnosis of fungous disease was considered, but treatment directed to that has not helped. Lymphangitis with swollen arms and tender axillary glands have occurred twice.

M.D., Montana.

Answer.—The relationship between eczematoid dermatitis and the sex hormones is quite vague. The condition may clear up or get worse during pregnancy. Often it becomes aggravated in the premenstrual phase. There is little scientific evidence which would indicate that the ovarian hormones themselves have any direct action in producing a dermatitis, although it is known that there may be an effect on skin at the times when the estrogenic titer of the tissues is elevated. This may account for certain cases of premenstrual edema, premenstrual acne, pigmentations of the skin during pregnancy, pigmentation of the nipples with maturity and certain other uncommon dermatologic lesions of various types associated with pregnancy. A deficiency of estrogens either at the menstrual period, at which it is temporary, or a constant one at the menopause will result in an increased capillary fragility with a tendency to purpura.

There is the likelihood that the eczema in this patient is of neurogenic origin, although some evidence seems to indicate a possibility of an allergic basis. There does seem to be a typical pattern in this case often seen with psychogenic disorders, relief being obtained with a number of different procedures temporarily but becoming ineffective on repetition of therapy. Relief is obtained, then, through the power of suggestion. It is possible that during pregnancy the patient felt free of responsibility and received more attention, so that some of the nervous tension contributing to the severity of the dermatitis was removed. It is significant that the relief from the dermatitis was shorter after each of three pregnancies, as her return to active duties involved more and more responsibilities.

It is suggested, therefore, that the psychic factors be analyzed to determine whether or not they may play a major role. Treatment would then be based on the results obtained following investigation into this aspect of the patient's condition. It is expected, however, that certain therapeutic measures will be applied as is usual with such cases, such as refraining from washing with water, the use of synthetic detergents instead of soap, and only the mildest of ointments to eliminate irritations of nonspecific nature.

ENDOCRINE OR ANDROGEN THERAPY AND ENDOMETRIOSIS

To the Editor:—A white woman aged 40 had a hysterectomy and oophorectomy because of a widespread endometriosis with questionable implants on the peritoneum of the intestines. My question is, What is the present consensus on the use of estrogens for menopausal symptoms in this type of case? If estrogens are safe to use is there any particular time element before they are started?

M.D., Indiana.

Answer.—Estrogens should not be used in the presence of endometriosis because they may reactivate endometrial tissue which is present and also bring about a return of pain. Faulkner and Riemenschneider (*Am. J. Obst. & Gynec.* **50:**560 [Nov.] 1945) reported a case of severe periodic bleeding from endometriosis of the bowel requiring over seventy partial or whole transfusions. Oophorectomy was finally done in December 1941 and the patient remained well until June 1942, when diethylstilbestrol was administered for menopausal symptoms and severe rectal bleeding recurred.

When women develop menopausal symptoms following an operation for endometriosis they should be given testosterone propionate. Usually a 10 mg. tablet taken by mouth daily will give relief, especially if supplemented by 16 mg. of phenobarbital three times a day for a few days at a time. In many instances phenobarbital alone will relieve menopausal disturbances.

PROCTOLOGIC SURGERY OF THE LARGE BOWEL

Chairman's Address

MARTIN S. KLECKNER, M.D.
Allentown, Pa.

The hundredth anniversary of the birth of the American Medical Association provides adequate cause for celebration. Were it not for the undeniable progress that the physicians of this country have made through their achievements many people throughout the whole world would not have healthier, happier and longer lives today. The accomplishments of physicians and their co-workers have been the result of endless hours of study, sickness and sacrifice. Many of them unstintingly gave the best years of their lives and refused opportunities to sell their discoveries for fabulous remuneration. Their research developed better treatment and provided absolute cure to many sufferers.

The Section on Gastro-Enterology and Proctology, of which it is my distinguished honor to be chairman, was brought into existence by the efforts of such proctologists as Drs. Joseph M. Matthews of Louisville, Ky. (the first president of the American Proctologic Society); Dwight H. Murray of Syracuse, N.Y.; Louis J. Hirschman of Detroit; Alois B. Graham of Indianapolis; William M. Beach of Pittsburgh; J. Rawson Pennington of Chicago, and others. The gastroenterologists prominent in this section's definite establishment in 1917 at the New York meeting of the American Medical Association included Anthony Bassler of New York, Horace W. Soper of St. Louis, Frank Smithies of Chicago, Franklin W. White of Boston and Joseph Sailer of Philadelphia. These are but a few of the outstanding proctologists and gastroenterologists in this country who have elevated the status of their respective specialties and provided the real backbone for this present splendid section. Since its organization it has been the yearly custom to alternate the chairmanship between the proctologists and the gastroenterologists so that fifteen proctologists and fourteen gastroenterologists have served most creditably as chairman.

Because of the increased interest among the members of the American Medical Association in these two specialties during the past decade, their sectional meetings have become somewhat crowded, not only in members but in material wealth, with the result that it may be necessary in the near future to divide and create separate sections (in Gastro-enterology and Proctology).

Were it not for the two great national societies, the American Gastro-Enterologic Association, which was founded fifty years ago and now comprises a membership of over two hundred, and the American Proctologic Society, which was born in 1899 and now has a roster of two hundred and fifty fellows and associates, this Section of the American Medical Association could never function. It is because of the members in these two outstanding organizations that the definite principles of the study, diagnosis and treatment of the various parts of the entire digestive system from OO (oral orifice) to AO (anal orifice) are so well presented.

Much progress has been made in the surgical technic of all specialties in the past few decades. In emphasizing proctologic surgery of the large bowel, it might be well to evaluate the changes in colon surgery during the last quarter of a century. It is interesting to note that in the constitution of the American Proctologic Society this science is defined as the "study, diagnosis and treatment of diseases of the anus, rectum and colon." For many years this organization has demanded general surgical training primarily, and when this training is combined with adequate proctologic instruction, a fellowship is obtainable.

Curiously enough, the word proctology comes from the Greek words Πρωκτός (proctos) meaning anus and λόγος (logos) meaning discourse, so that the original interpretation refers to a "discourse on the anus," although the scope of modern proctology has far exceeded this early designation.

Nevertheless, some members of the medical profession still seem to think that these medieval limits remain. It is known that all surgical specialties are the outgrowth of general surgery, which must be regarded as the parent stalk. With the progression of every specialty, so in proctology—surgeons became more interested in this field of activity, and because of their more intent study and the limitation of their work they became more adept in the treatment of proctologic disease. While the proctologist's superiority in his specialty is recognized and he deserves much praise, the parent has been most hesitant or loath to recognize its offspring or to admit that in certain respects the scion has surpassed the parent in fruition. Many of the older proctologists confined their efforts to diseases of the anorectal area, but the present personnel of the American Proctologic Society with few exceptions are colon trained and colon minded. They must be prepared to satisfactorily treat any surgical problem which may become apparent when the abdomen is opened. The anatomic structure of the terminal portion of the bowel is decidedly complicated and involved. Considerable study and practice is required in order to obtain the most satisfactory results without injuring

Read before the Section on Gastro-Enterology and Proctology at the Ninety-Sixth Annual Session of the American Medical Association, Atlantic City, N. J., June 12, 1947.

or destroying its muscular mechanism. I am not a believer in the short courses in proctology that are offered to physicians, because the instruction given is inadequate and leads the novice to believe that he can satisfactorily treat such pathologic conditions. As a means to broaden his diagnostic field and to aid in the correction of some of the minor conditions so frequently encountered, I believe it should prove beneficial to both physician and patient. My main objection to most of these attempts at cure is to the cursory methods employed to examine the area above the existing lesion. Frequently a poor history is taken, coupled with an inadequate physical examination. When the physician is cognizant of the fact that the area proximal to the anorectal or pectinate line (which is approximately 1½ inches, or 3.8 cm., from the anal orifice) is devoid of sensory nerve or pain fibers, then only will he realize that serious danger may lurk beyond the reach of the gloved finger and may require the use of the lighted sigmoidoscope or the opinion of the trained roentgenologist, who by the use of the double contrast barium-air enema may interpret factors not visible to the naked eye. Frequently several of these "roentgen seances" are necessary to determine the presence or show the absence of the various colonic lesions.

Table 1.—*Incidence Rates in Four Hundred and Forty-One Cases of Cancer of the Large Bowel, 1931-1946*

	Cases	
Age	No.	%

Unfortunately many surgeons are of the opinion that it is a simple matter to cure an extensive fistula in ano complicated by numerous tracts or properly to drain and cure some of the enormous abscesses so frequently encountered around the terminal area of the bowel. They fail to realize that such abscesses are part and parcel of associated fistulas, which were the primary cause of the purulent collections. Rectal prolapse, which is frequent in advanced hemorrhoidal disease, will often make the operative procedure an exceedingly tedious one, because absolute cure and proper function are mandatory. The pilonidal sinus (cyst) regarded so lightly by many wielders of the "aseptic scalpel" may prove extremely hazardous to the success of any surgeon if it has many associated ramifications. How many of these patients are given proper sigmoidoscopic examinations prior to surgical intervention, and what kind of postoperative care do they receive? Seldom should any of the aforementioned proctologic conditions require more than the initial operative procedure. To tell the patient that the condition has recurred is invariably an admission on the part of the surgeon that the first operative procedure was not properly performed. Unfortunately there are entirely too many physicians trying to do work for which they are inadequately prepared. To admit one's limitations in certain fields of surgical activity should be regarded as an asset, but it certainly is a liability to those who continue to do poorly the work which their colleagues can perform more proficiently. There have been many instances in which operation on some of the previously mentioned proctologic conditions entailed more difficulty than I might have encountered in performing some resection of the colon proper or a one stage Miles operation.

Table 2.—*Location of Lesion*

	Cases	
Location * (large bowel)	No.	%
Retrorectal	3	0.7

All physicians remember those early days when large majority of them, as "embryo doctors," express a desire to become *surgeons or specialize in some pa* ticular branch of medicine. Time, lack of money, t establishment of a good general practice and ofttim a large family prevented these practitioners from acti participation in advanced study. Others less hand capped continued to pursue postgraduate work an when fully qualified were permitted to take Boa Examinations for Certification. I have often wondere whether there would have been a higher percentage first rate specialists from the former group, who di not have the opportunity to go on, than from those wh were able to continue their postgraduate educatio My own conclusion has been that every physician ha a particularly important job to perform, whether h be a general practitioner or a specialist. Only fron those who believe that they can always improve thei diagnostic routine and better their methods of treat ment may the best results be expected. In my contacts with the laity I have learned that the patient is often afraid—afraid of what the physician will tell him—an as a result he frequently puts off seeking medical advic at all until it is too late to help him. Some conditions of the large bowel, to cite chronic nonspecific ulcerative colitis and the erroneously labeled spastic, or mucous, colitis as good examples, can be legitimately and profitably studied from the psychosomatic point of view. Surgical procedures may remedy the former condition, but an entirely different approach is necessary to cure the latter disease, because it calls for an understanding and appraisal of the patient's problems. Resourceful therapeutic measures can only be administered after one has gained the complete confidence of the patient. It is not unusual to acquire this when some good sensible advice and "plain speaking" by the consultant has been judiciously expressed. This does require time, but it gets results because it is the most important part of the entire treatment. I have never been impressed by those who omit this phase because they are "too busy."

Most proctologic diseases can be successfully treated. In regard to chronic ulcerative colitis and ileitis I would refer every one of you to those splendid papers submitted in the past year or two, in which analyses and treatments have been definitely outlined by proctologists and gastroenterologists alike. Cancer of the bowel usually offers its greatest problem in that the malignant growth has been permitted to advance too far in too many patients to permit of good prognosis. No one disputes the fact that a good surgeon with the aid of competent, trained assistants and experienced anesthetists cannot help but get the best results when performing colonic surgery, whether the malignant process is fairly well localized or even far advanced. Good percentages of cure and a low death rate can be readily assured if the surgeon draws a definite line on operability. Preoperative and postoperative care have been improved and modified so that today one can readily help those whose condition was regarded as hopeless fifteen years ago. While the truth still prevails, that the curability of cancer varies inversely with the duration of the disease, greater success in achieving surgical accessibility to all tumors has been experienced.

Table 5.—*Time Interval (Fault of Physician) from Consultation of General Practitioner Until Specialist (Surgical) Aid Was Urged*

Referred to Specialist	No. of Patients
At once	25
Less than 1 mo.	8

The symptomatology of cancer is being broadcast regularly to both lay and medical persons, but it is equally important that all become more cognizant of the precancerous period and give full support and aid to those groups endeavoring to detect lesions which may (without any apparent symptom) give proof that cancer is present or may shortly manifest early degenerative changes. It is to be hoped that the near future will bring some fairly simple test, so devised that any one exhibiting the slightest sign or symptom of early cancer may be properly screened and treated.

* One patient committed suicide.

Table 9.—*Additional Observations on the Diagnosis and Treatment of Cancer of the Large Bowel*

The majority of patients received salves, soapsud enemas or suppositories as initial treatment.

In 294 rectal carcinomas roentgenologic study, including barium enema, was done in 50 cases (17%). (Digital examination alone was necessary for diagnosis.)

Inoperable cases (117) included those of 12 patients with factitial proctitis.

In earlier cases when grading of specimens for biopsy was done, grade 3 comprised 51%, with grades 2 and 4 each 23%.

In 2 of my own cases in which operative intervention for acute strangulated hermorrhoids and painful fissure was done, a barium enema (double contrast air) study later revealed a carcinoma of the colon (high up).

In carcinoma of the rectum complicated by arterial hypertension, 1 patient (blood pressure 220/110) is alive after twelve years (two stage operation).
  (*a*) Diabetes mellitus: 10 patients (all died in 1 to 2 years).
  (*b*) Tertiary syphilis (no gumma): 5 patients (all died).

A summarization of data on 441 cases of cancer of the large bowel, in my private practice covering fifteen years, revealed (table 1) that 65 per cent were present between the ages of 50 and 70, slightly more frequent in men than in women, and (table 2) that 69 per cent were determinable with the gloved finger (if the digital examination was made to cover the distal 5 inches, or 12.7 cm.). Diverticulitis and polyposis both showed degenerative change (table 4) in 18 cases (4 per cent), but the figure for polyposis appears entirely too low because it is known that so many malignant growths have had their beginning in the apparently benign polyp. Change of bowel habit (table 3) was the earliest symptom obtainable from careful questioning of 304 patients, with the symptoms of bleeding and tenesmus following. When change in bowel habit was the second or third symptom to appear it was superseded by the aforementioned symptomatology. The time interval between the appearance of the first symptom and medical consultation (table 4) was appalling. It indicates a great need for "jet propulsion" methods in cancer education among the laity. A better but not too wholesome record is evident in the length of the interval between the patient's application for medical advice and his referral for surgical consultation (table 5). In this regard the poor record was due in great measure (tables 6 and 7) to wrong diagnosis and treatment, accounting for error in almost 23 per cent of cases. It is indeed a reflection on the real status of the physician consulted, and he alone can correct this inexcusable calamity. I must emphasize the importance of initial proctologic examinations (including proper sigmoidoscopic study) prior to all barium study of the colon and the value of taking specimens for biopsy. Let the proctologist ever be cognizant of the fact that no matter how efficient or nationally prominent he may be, he is liable to make some honest mistakes.

THE MASSACHUSETTS BLOOD AND BLOOD DERIVATIVES PROGRAM

LOREN D. MOORE, M.D.
Assistant Director, Division of Biologic Laboratories
GEOFFREY EDSALL, M.D.
Director, Division of Biologic Laboratories
and
VLADO A. GETTING, M.D., D.P.H.
Commissioner, Massachusetts Department of Public Health
Boston

Blood and the various products obtained from blood are now recognized as essentials for good medical care. A tremendous increase in the use of both whole blood and plasma has resulted from the military and civilian medical experience of the last few years. This has placed a steadily growing burden on both the patient and the facilities which provide these products—the patient because of the sometimes staggering charges which often accumulate when quantities of blood or plasma now considered adequate are administered, and the medical service because of the growing difficulty in actually finding sources for the increasing requirements of these substances. The cost, in particular, becomes prohibitive to many patients, unless means are found to reduce the costs through increasing the number of voluntary blood donations, through centralizing the expensive operations of procurement and processing and through equalizing channels of distribution, so that local shortages of specific blood types or products of blood will not in themselves contribute to the costs of procurement.

Blood is a peculiar commodity that cannot be manufactured in a test tube but must be obtained from human donations. Ever since blood transfusion was begun it has been possible to find, with sufficient effort, enough voluntary donors to provide a significant proportion of the quantities which are needed, and, with the establishment of preserved blood banks some years ago, the utilization of such donations was made much more efficient. The collection of over 13,000,000 pints (6,151,000 liters) of blood, voluntarily donated, from our citizens by the American National Red Cross during the war showed that a tremendous reservoir of this fluid existed in the veins of the generous-minded people of this country, as was shown also in England, Canada, Australia, South Africa and elsewhere. In turn, many communities have organized community blood banks, serving the entire hospital group of a given area, with a resulting increase in the uniformity of the supply and the efficiency of procurement. However, even a community program fails to meet all the requirements of an ideal blood program, for it tends to serve best only those communities which are already best served in other ways, and it may prove inadequate to carry the loads imposed by unusual emergencies which a larger program could absorb. It was partly on account of these limitations that Michigan, North Dakota, Illinois, Vermont and other states undertook and successfully operated statewide plasma programs during the recent war years.

The Massachusetts Department of Health pioneered fifty years ago in the provision of diphtheria antitoxin without charge for the treatment of any patient for whom a physician felt that such treatment was required. The therapeutic results and the consequent economic saving were salutary and have abundantly justified the institution of such a project and such a policy. The Massachusetts Department of Public Health, in accordance with this policy, investigated three years ago the desirability of establishing a statewide blood plasma program. Consultation was obtained with the medical society and hospital leaders and clinical and laboratory authorities, and a survey of the current requirements for blood and plasma was carried out through the Massachusetts Hospital Association. It was concluded that a statewide program was desirable, provided it met the following objectives: (1) The program should make available not only blood plasma, but preserved whole blood, red cells, and the various fractions of plasma—thus assuring the supply of all the derivatives of blood for which a need exists and insuring the most economic use of each unit of blood procured, and (2) the program should make these products available with equal facility to all communities and individuals in the state, irrespective of geographic or financial considerations.

Such a program was made possible with the appropriation of a sum set aside by the legislature for this purpose in July 1945. Since that time, the program has gotten under way and has, with certain important limitations, begun to meet the objectives as originally outlined. The Massachusetts Blood Program may be considered unique in that it is the first comprehensive statewide blood program in operation. Other states have undertaken the provision of blood plasma, and some counties and cities have developed whole blood banks, but none has a program which includes processing and distribution of whole blood, red blood cells, blood plasma and the fractions of blood plasma without charge.

The aim of the Massachusetts Blood Program is to provide all the blood and blood products required by the residents of the commonwealth. No charge is to be made for any of the products, regardless of the financial status of the recipient. However, hospitals or physicians may make the usual administration

---

Read before the Section on Preventive and Industrial Medicine and Public Health at the Ninety-Sixth Annual Session of the American Medical Association, Atlantic City, N. J., June 13, 1947.

charge. The experience gained from this program may therefore be of especial interest in the light that it may shed on the accomplishments of such a program and some of the problems which must be met.

A statewide program of this type is particularly beneficial to the small hospitals that use a small amount of whole blood. Many such hospitals are not equipped or staffed to operate blood banks, and to do so would entail a large expenditure of funds. With blood available at subdepots in neighboring hospitals, the small hospitals have only to do blood grouping and Rh typing, obtain blood from the subdepot, and cross match before giving the transfusion. Blood supplied in this manner may prove the difference between life and death, since considerable time is required to locate a donor, type, cross match and bleed to provide blood in an emergency.

Public health, medical and hospital authorities in Massachusetts realized that the stimulus derived from the use of blood and blood products in the armed forces would be reflected in civilian medical practice after the war; also, that the American public was well aware of the virtues of and needs for blood and blood products for general public use, because of the extensive education derived from the blood procurement program established during the war by the armed forces and the American Red Cross.

As early as 1937, the American Red Cross authorized a few selected chapters to carry on an experiment in the enrolment of volunteer blood donors to be available on calls from hospitals and physicians for blood donations free of charge to those not able to pay for them. Subsequently the Red Cross participated through its local chapters in developing community blood and plasma bank services and, on a national scale, in the gigantic wartime blood procurement program. Toward the end of the war this experience had led to a widespread demand that the Red Cross render a similar service to the civilian population. On the advice of numerous professional groups and with the guidance of a distinguished expert advisory committee, the American National Red Cross approved participation of chapters in civilian blood programs on a far broader basis. Several significant provisions were set up—chiefly that the program be sponsored by a reliable medical or health agency which was to be responsible for the technical operations; that the Red Cross be responsible only for enrolment of donors and nontechnical aid; that the program be acceptable to the medical profession in the community, and that no charge be made to physicians, hospitals, clinics or patients for the products made available through such a program. On the basis of these requirements established by the American National Red Cross, the Massachusetts Department of Public Health proceeded to develop a plan for a statewide blood program.

Briefly, the plan for the Massachusetts Blood Program is to collect blood from volunteers in all communities. This is done by a "bloodmobile" visiting communities on a prearranged schedule. The "bloodmobile" staff consists of a physician, five nurses, a medical technician, a blood custodian and a truck driver. The unit carries all technical equipment required in the clinic. The physician is responsible for the operation of the clinic and the selection and care of donors. The nurses do the actual bleeding under the supervision of the physician and assist the physician in selecting donors by medical history. The medical technician determines the hemoglobin, blood group and Rh factor of each donor. The blood custodian is charged with the care, refrigeration and storage of the bloods collected and with seeing that the bloods are delivered to the central laboratory each night. The truck driver not only drives the truck that carries the equipment but assists in setting up and breaking down the clinic; he also assists generally in the operation of the clinic.

Donors are recruited locally by the chapters of the American Red Cross. The successful recruitment of donors demands continuous and well organized local publicity. Various social, fraternal and civic organizations and groups must be interested in the program, and through their participation the members of the organization are acquainted with the program and as residents of the community actively engage the community in the program. The Red Cross chapters also provide the place for the clinic and provide nontechnical equipment and personnel for the operation of the clinic. The space for a six bed clinic requires a minimum of 1,500 square feet (139.35 square meters). This may be a single room divided by curtains or screens into a registration room, 500 square feet (46.45 square meters); a donation room, 500 square feet; a recovery room, 100 square feet (9.29 square meters), and a canteen, 400 square feet (37.16 square meters); or connecting rooms of adequate size may be used. Kitchen facilities to provide a light lunch for donors after donations should be available. Rest room facilities and utilities for the immediate washing of needles, tubing and other equipment must be available. American Red Cross staff assistants, gray ladies, nurses' aides, canteen personnel and motor corps personnel comprise the nontechnical personnel required.

At the start, the Massachusetts Blood Program was divided into three phases. The first was to procure bloods for the preparation of blood plasma. However, the abrupt ending of the war and the return of the surplus armed forces plasma to state health departments provided a sufficient amount of plasma to meet the present needs. The second phase of the program was to collect blood to be used for fractionation. Fractionation would provide antihemophilic globulin, thrombin and fibrinogen for the preparation of fibrin films and fibrin foams, blood-grouping globulins and anti-Rh typing serum, immune serum globulins and salt-poor albumin. The third phase, so placed because of the many technical difficulties to be encountered in distribution and storage, was to provide whole blood.

Because of the highly technical nature of processing and distributing blood and blood products, it was necessary to provide a special addition to the Massachusetts Department of Public Health Division of Biologic Laboratories building. Many delays were encountered in construction and procurement of equipment. The blood collection program actually began on Dec. 3, 1945, and moderate scale fractionation began approximately ten months later, on Oct. 15, 1946. Because of the delay in obtaining equipment for fractionation and the procurement of a fair supply of whole blood, it was decided to begin limited distribution of whole blood in September 1946. The institution of this third phase provided a means of working out some of the technical problems of distribution of whole blood.

From the inauguration of the program, on Dec. 3, 1945, to May 31, 1947, the "bloodmobile" has visited 153 communities to hold 236 clinics. During this period 19,204 blood donors have been registered; 2,828 have been rejected for one reason or another, and 297 persons having rare blood groups or Rh-negative blood have remained on call as volunteer donors in the community. A total of 81 bloods have been sent from the clinic directly to local hospitals for emergency use, and 15,990 bloods have been returned to the central laboratory for processing.

TABLE 1.—*Use of Blood and Blood Plasma in Massachusetts Hospitals, 1943*

Hospital Group	Number	Total Beds	Units of Plasma and Blood Used: Blood 500 Cc. Total	Blood 500 Cc. Per Bed	Plasma 250 Cc. Total	Plasma 250 Cc. Per Bed
Blood bank........	27	8,540	17,482	2.05	4,780	0.56
Plasma bank......	16	1,286	953	0.74	1,039	0.81
Nearby bank.......	30	2,385	1,452	0.61	1,792	0.76
No facilities........	20	2,610	697	0.26	942	0.36
Total............	94	14,821	20,584	....	8,553	....
Average..........				1.4		0.58

Of the 15,990 bloods delivered to the laboratory, 314 were rejected as not suitable for whole blood or for processing to blood plasma or fractions. Of the remainder, 8,195 have been processed to whole bloods, 274 have been made into plasma and 7,204 have been used for fractionation.

One of the most interesting phases of this program has been the noticeable increase in the use of blood and blood plasma. A sufficient stock pile of plasma fractions has not yet been accumulated to allow general distribution of fractions on a large scale, and fractions have been used in only a limited way for clinical trials.

Table 1 gives the results of a survey of Massachusetts hospitals in 1944 and shows that the 94 hospitals replying to the questionnaire and having a total bed capacity of 14,821 used a total of 20,584 standard 500 cc. units of blood for an average of 1.4 units of blood per hospital bed per year in 1943. During the same period, these hospitals used 8,553 small, or 250 cc., units of blood plasma for an average of 0.58 unit of plasma per hospital bed per year.

TABLE 2.—*Blood and Blood Plasma Used in Massachusetts Hospitals; Hospital Survey for 1946 (Public Health Districts)*

	Hospitals Reporting	Total Beds	Blood Banks	No Banks	Uses — 1946: Blood	Plasma 500 Cc.	Plasma 250 Cc.
District I.........	6	946	2	4	942	831	134

Totals.........	78	9,587	23	55	27,065	6,540	2,647

Early in 1947 questionnaires were sent out to all hospitals in the commonwealth, and replies have been received from 78 hospitals having a total of 9,587 beds, as shown in table 2. These hospitals used 27,065 standard 500 cc. units of whole blood, for an average of 2.8 units of blood per hospital bed per year for 1946. The use of plasma also increased, and the hospitals report the use of 6,540 large, or 500 cc., units of plasma, for an average of 0.6 unit per hospital bed per year, and 2,647 small, or 250 cc., units of plasma to give an average of 0.27 unit per hospital bed per year. The combined total of plasma is equivalent to the use of 15,727 small, or 250 cc., units of plasma or 1.6 of these units per bed per year.

The hospitals reporting on this survey estimated the 1947 requirements for blood and plasma. The 78 hospitals estimated 33,173 bloods would be required for 1947, or an average of 3.4 standard 500 cc. units of whole blood per hospital bed per year. It is expected that 8,825 standard 500 cc. units of plasma will be used, for an average of 0.9 unit per hospital bed per year, and 2,634 small, or 250 cc., units, for an average of 0.27 unit per hospital bed per year. In terms of 250 cc. plasma units, this represents an average of 2.1 units per bed per year.

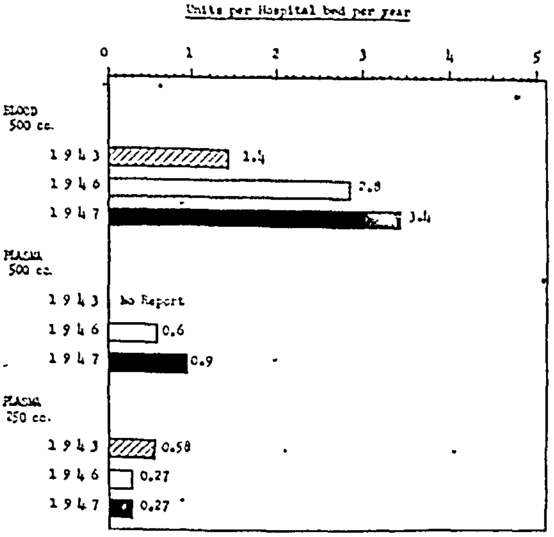
The use of blood for the years 1943 and 1946 and the anticipated needs for 1947 are summarized in table 3. Because very few 500 cc. plasma units were used in 1943, all units were reduced to the 250 cc. unit size. However, with the return of the surplus armed forces plasma and subsequent distribution to all hospitals in the commonwealth in March 1946, the use of double size plasma units has increased. There is an increase of 6,481 in the use of blood during 1946 over 1943, and in 1947 the estimated increase is 6,108 over 1946. The increase in the use of plasma is not so great and stresses the increased use of whole blood with a relative decrease in the use of plasma. The chart presents the graphic picture of the increased use of blood and blood plasma during 1943 and 1946, with the estimated amounts required in 1947 by the Massachusetts hospitals replying to the questionnaire.

TABLE 3.—*Amount of Blood and Blood Plasma Used in Massachusetts Hospitals in 1943 and 1946; Estimated Uses, 1947; Consolidated Data from Hospital Surveys*

Year	Hospitals Reporting	Total Beds	Units of Blood and Plasma Used: Blood, 500 Cc. Total	Blood, 500 Cc. Per Bed, Aver.	Plasma 500 Cc. Total	Plasma 500 Cc. Per Bed, Aver.	Plasma 250 Cc. Total	Plasma 250 Cc. Per Bed, Aver.
1943............	94	14,821	20,584	1.4	.....	...	8,553	0.58
1946............	78	9,587	27,065	2.8	6,540	0.6	2,647	0.27
1947............	78	9,587	33,173	3.4	8,825	0.9	2,634	0.27

To meet the blood and blood products needs, it is necessary to consider the number of bloods required to produce the products to be distributed. Also, consideration must be given to the donors required to meet these needs. For every group of donors recruited for donation, there are rejections because of acute colds, low hemoglobin levels, a history of jaundice and other causes. Those rejected plus those that fail to keep the appointment will average about 25 per cent. Of all bloods collected, an average of 10 per cent cannot be used for whole blood, but most of these can be used for fractionation. Bloods from a donor with a history of malaria or a tour of duty in malarious areas without a known attack of malaria cannot be used for whole blood but can be used for fractionation. Bleeding difficulties sometimes cause a short bleeding, and such bloods must be used for fractionation.

In table 4 the blood requirements for the year 1947 are given. These results are based on the total hospital beds in the hospitals of the commonwealth as of March 1, 1946. The state and county hospitals are not included in this table, since many of these institutions use little blood or blood products and have a large bed capacity.



Comparison of use of blood and blood products in Massachusetts hospitals in 1943, 1946 and 1947; the data are from hospital surveys.

The hospitals in the state of Massachusetts have a total of 21,312 hospital beds. Using the 1947 estimated figure of 3.4 units of blood per hospital bed per year shows that 72,460 usable 500 cc. units of whole blood will be required. To provide 500 cc. units of plasma, it will require 47,950 bloods, since 2.5 usable 500 cc. units of whole blood are required to provide a 500 cc. unit of plasma. Likewise, it will require 5,328 usable 500 cc. units of blood to provide the required number of 250 cc. units of plasma. Salt-poor albumin has not been available for unlimited civilian hospital use, and the quantity of salt-poor albumin must be estimated. It must be stressed that this estimate is without actual experience tables. Since it requires 4 usable 500 cc. units of whole blood to make a single 100 cc. unit of 25 per cent albumin, albumin demands being estimated to be equal to or greater than the plasma estimate for 1947, this assumes a demand for the maximum predicted plasma needs and an additional equivalent of albumin needs for unforeseen purposes such as nephrosis, eclampsia and emergency shock treatment. Disregarding the probability that use of blood and plasma may recede, since there is at present considerable waste, it is estimated that 93,768 usable 500 cc. units of whole blood are required to meet the estimated needs for albumin. From these totals, it can be seen that 219,506 usable whole bloods are required if the estimated hospital needs for whole blood, plasma and fractions are to be met in 1947.

With two "bloodmobiles" operating each day, five days per week, each unit staffed and equipped to collect 100 to 125 bloods per day, approximately 50,000 bloods can be collected. This will not meet the estimated needs for whole blood for the year 1947. Before adding additional collection units, the response of the residents of Massachusetts must be ascertained to be sure that they will donate the bloods required for the estimated needs of the coming year.

In order that the donor and the immediate members of the donor's family may be protected for blood needs for one year with a limited supply of blood, it has been necessary, for the time being, to limit blood for use of donors and immediate families except in genuine medical or surgical emergencies. Supplies distributed to hospital blood banks are used for nondonors and are replaced by bleeding at the hospital blood banks or at the mobile unit when it next visits the community or is in a neighboring community. The restriction of blood for donors and immediate families should increase donations of blood, for many families desire the protection for their blood needs just as they desire the protection of the Blue Cross or Blue Shield. Also, bloods are obtained from many that would not otherwise donate if all blood needs were provided without requiring a donation of blood. It is believed that donations of blood will eventually be sufficient to meet all needs without any restrictions on the use, but in contemplating or planning for this it is stressed that any blood program must be set up so that when there is a decrease in donations a means is readily available to limit the use of donated blood. This limitation then stimulates the incentive for individuals to participate in the program and thus provide more blood. Also, this stimulus may be obtained by making a small charge for the blood or by strict use of blood for the donor's protection only.

Whether sufficient "bloodmobiles" and personnel are provided to collect all bloods required or not, it is most essential that all hospitals operating blood banks should continue to collect bloods whenever possible. An established hospital blood bank has adequate facilities to store, check and distribute whole blood and blood products. The use of such blood banks as subdepots provides a means for distributing these products to neighboring hospitals that lack these necessary facilities. The responsibility for the administration of the proper blood group and Rh type blood to a recipient remains with the physician, although the actual technical work may be delegated to the hospital laboratory or blood bank. Again, the hospital blood bank may play an important role in the program by collecting blood from volunteer donors between "bloodmobile" visits to the community and also blood as replacements for that used for nondonors. The actual participation of hospitals and physicians in the program, along with residents of the community, insures a [illegible] munity program which aids materially [illegible] plete community partic[illegible]

Table 4.—*Massachusetts Blood Requirements, 1947, Based on Hospitals Reporting, Exclusive of State and County Hospitals*

Product	Hospitals	Total Beds	Units per Bed per Year	Bloods to Provide	Usable Whole Bloods Required, Units
Blood	184	21,312	3.4	1	72,460
Plasma					
500 cc.	184	21,312	0.9	2.5	47,950
250 cc.	...	......	0.2	1.25	5,328
Albumin (estimated)	184	21,312	?	4.0	93,768
Total					219,506

ABSTRACT OF DISCUSSION

Dr. I. Jay Brightman, Albany, N. Y.: In New York state we are also attempting to get a blood program under way. We are doing it somewhat differently from Massachusetts. Our plan is for an entirely decentralized type of program. Geographically, we are about three times the size of Massachusetts and a centralized program would be most difficult to manage. Also, we are operating on a state aid to community basis; the state is providing financial aid, but the community is responsible for 50 per cent of the cost of operation. In surveying the New York state hospitals we found that a state program was definitely indicated, partly because many hospitals had poor facilities for making blood readily available and partly because of low standards governing laboratory and clinical procedures in some hospitals operating blood banks. As an example of the latter, we found one hospital running as high as six blood transfusions per hospital bed per year. Their record of reactions was almost nil, which was surprising until the record and supervision systems were received. Obviously, if you keep no records and maintain no medical supervision, you will have no reactions to show. I should like to mention the high incidence of homologous serum jaundice which we are encountering in New York state. We know from other reports that there is a significant amount of jaundice following the administration of pooled plasma, far beyond that following whole blood transfusion. This is apparently due to the pooling of plasma with greater dissemination of the virus. We made a follow-up study of recipients of pooled plasma and found the incidence of jaundice to vary from 3 to 5 per cent. We have encountered some deaths. These findings call for education in the field of transfusion therapy, so that pooled plasma may be administered only when absolutely indicated. I have had the opportunity of visiting the Massachusetts laboratory and of observing the work of Dr. Moore and his associates. I believe that they are blazing a trail in this new field of public health and are to be congratulated.

Dr. Claude P. Brown, Philadelphia: I should like to know the probable cost for 1947 of such a program as Massachusetts has.

Dr. J. W. Mountin, Washington, D. C.: I should like to ask: 1. How is the Massachusetts program to be articulated with that being developed by the Red Cross? 2. What has been your experience in getting donors; is the problem difficult and what inducements do you offer? 3. Is the processing done directly by the State Health Department or under contractual arrangements with other agencies?

Dr. Loren D. Moore, Boston: We are having a similar experience with the use of plasma in the development of jaundice, and it is reaching a point where many of the hospitals are scarcely using plasma at all, but are using blood. A number of hospitals operating large scale blood banks are now using individual bleedings of plasma, by that method administering typed plasma to eliminate the hazard of jaundice. This is not a feasible program on a statewide basis, but it is something that we must consider. If the indications continue, the use of albumin will, I think, definitely replace that of plasma. So far the indications are that the jaundice virus is not carried over in the fractionation process, and we have a stable product without the hazard of transmitting the virus. Another great factor in favor of the albumin is that it is a small unit, can be carried in a physician's bag and can be administered readily at any place, and is very stable at ordinary temperatures. It is costing us now about $2 to $3 to collect blood in the field. That is high because our units are not operating 100 per cent every day. If our units could operate and collect 200 to 250 units a day, our cost would be definitely below $2 a unit. I cannot give you any definite cost figures on the plant operation. As to Dr. Mountin's questions, let's take the third question first. The work is all done in one central laboratory operated by the Department of Public Health. It is part of the Division of Biologic Laboratories. Getting donors is a problem. Our percentage of repeat-donors is, I should say, about 75 per cent. That is not good. We want new donors, and we want to do blood grouping and Rh typing eventually on the entire population of the commonwealth. We are now increasing our number of new donations.

Dr. Mountin: The relationship of the Red Cross—I think that you refer to the national program that the Red Cross has been investigating.

Dr. Moore: Yes, that is it. We have no connection, of course, with that. If that program goes through, it will be a number of years before it actually engages all of the states in the United States, and we are going ahead with our program just as though there were no talk of a national program. Just how we will fit into that program has, of course, not been determined. No doubt our laboratory will be used, probably for processing blood for the New England area. We believe that our plant will be used for the over-all program in some manner, and for that reason we are going ahead.

THE PHYSIOLOGIC BASIS OF MENSTRUATION: A SUMMARY OF CURRENT CONCEPTS

S. R. M. REYNOLDS, Ph.D.
Carnegie Institution of Washington, Department of Embryology
Baltimore

The physiologic basis of uterine bleeding in primates is a subject of perennial discussion. In this article I propose to present a series of related facts pertaining to menstruation. Some of these facts are so recently acquired that it is impossible to incorporate them with certainty in the older views of the subject. This amounts to saying that new discoveries remain to be made.

The physiologist recognizes that the first step in the explanation of menstrual mechanisms is an understanding of the morphologic characteristics of that part of the peripheral vascular tree which undergoes the menstrual process. This is particularly true today, since newer knowledge of a histologic nature makes it necessary to revise and enlarge the existing ideas concerning menstruation. On one hand Danish workers, notably Okkels and his students Schlegel and Dalgaard, have recently demonstrated in the human endometrium the probable presence of numerous arteriovenous anastomoses (Okkels, 1947;[1] Schlegel, 1945-1946;[2] Dalgaard, 1946[3]). On the other hand Kaiser, studying in the Carnegie laboratory, has noted that certain New World monkeys are lacking in endometrial coiled arterioles in the endometrium at all times of the menstrual cycle (Kaiser, 1947[4]). Since these monkeys do menstruate, it is clear that the basic mechanisms of menstruation are not dependent on the highly specialized structures of spiral arterioles and arteriovenous anastomoses. More will be said of this later.

Until now it has been the fashion to dwell on the coiled, or spiral, arterioles in the endometrium. For orientation, the vascular pattern in the uterus may be compared with the components of the peripheral vascular tree in other parts of the body. These are shown schematically in figures 1 and 2, respectively.

[4] Kaiser, I. H.: Absence of Spiral Arterioles in the Endometrium of Menstruating Platyrrhine Monkeys, Anat. Rec., November 1947, to be published.

In figure 1 the essential features of the peripheral vascular tree in somatic tissues in general are shown (after Zweifach and Shorr[5]). Arterioles, having muscular elements, arise from terminal arteries. The arterioles give rise to three types of vessels, namely, dichotomous branches of arterioles, precapillary arterioles with contractile elements and arteriovenous anastomoses.

In figure 2 are seen the specialized structures which have been described as existing within the human uterus. The myometrium contains the principal arterial and venous supply. The arcuate arteries in the vascular zone give rise to terminal arteries supplying the outer third of the myometrium. The inner two thirds of the myometrium is supplied by branches from the radiate arteries as these pass toward the endometrium. In the endometrium the radiate arteries continue as spiral, or coiled, arterioles. The basalis of the endometrium is supplied by endometrial basilar arterioles, which divide once dichotomously and end in a rich capillary network. The functionalis is supplied by the spiral arterioles. These give rise to few branches until their terminal branching.

When one compares the structural features of the somatic peripheral vascular tree with that in the human uterus, one sees many features in common. The principal differences lie in the presence in the premenstrual human uterus of many supposed arteriovenous anastomoses, numerous endometrial coiled arterioles and extensive, subepithelial, venous and capillary lakes.

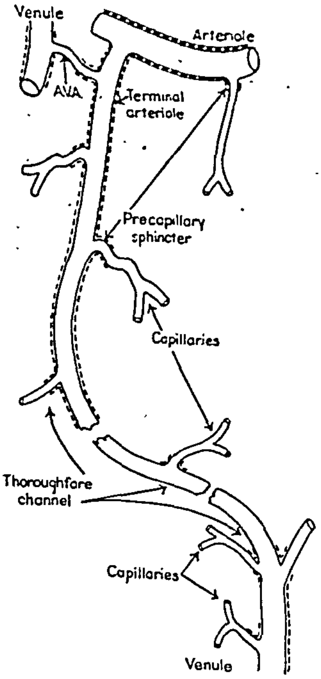

Fig. 1.—Schematic representation of the principal blood vascular elements in the general somatic circulation. Contractile elements are indicated by broken lines. Note contractile elements about precapillary vessels and the arteriovenous anastomoses (A.V.A.). After Zweifach and Shorr.[5]

Of equal importance with the vascular architecture is the seldom emphasized fact that the tissue in which these structures lie is loose and spongy. The vascular elements appear to be developed out of all proportion to the immediate metabolic requirements of such tissue. It is most likely that the vascular arrangement in the endometrium is adapted, as Hasner (1946)[6] has emphasized, to supplying rapidly the placental villi of an invading trophoblast when an ovum begins to become implanted. When a trophoblast fails to develop, however, this complex vascular structure breaks down. It cannot be maintained in the face of the requirements of cyclic endocrine activity, in which ovulation is normally the key point in the pattern. Menstruation will take place, it is true, in anovulatory cycles as is now generally recognized. This is a common occurrence in rhesus, although it is regarded as being uncommon in women during the period of maximum fertility. In either case, however, observations of Daron (1936)[7] show that the sequence of events is the same. The degree of vascular development is much less, however, when a cycle is anovulatory than it is when ovulation and development of a corpus luteum takes place. This has been affirmed in recent studies by Markee (1940)[8] and Kaiser (1947).[9] In either event the demands of cyclic endocrine activity impose the necessity of tearing down the vascular bed in the spongiosa if it cannot fulfil its predestined function of supplying a trophoblast. It is the reason for, and consequence of, this collapse that is of concern here.

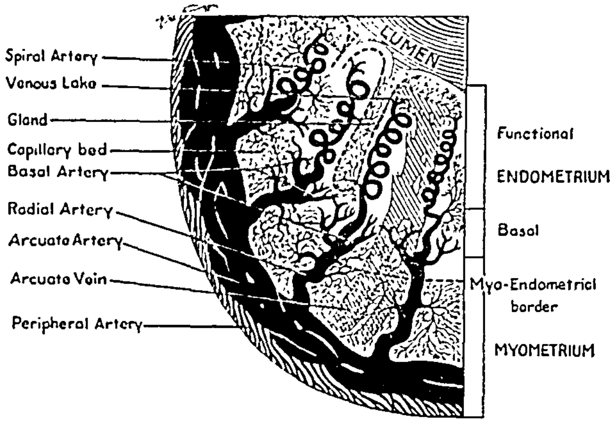

Fig. 2.—Schematic representation of the specialized vascular elements in the human uterus. Note different vascular elements supplying the myometrium, the basal and the functional layers of the endometrium. Based on summary of the literature and illustration of it by Schlegel (1945-1946)[2] and by Okkels and Engle (1938).[11] Note alleged arteriovenous anastomoses into the subepithelial venous lake.

VASCULAR PATTERNS AND THE MENSTRUAL CYCLE

The essential features of the vascular architecture of the human uterus during the menstrual cycle are shown in figure 3. In brief, it may be noted that these are as follows:

During the proliferative phase, one finds that (*a*) there are few coils in the endometrial arterioles and these tend to be restricted to the lower portion of the functional zone; (*b*) collecting veins are very small; (*c*) arteriovenous anastomoses, according to Schlegel (1945-1946),[2] are few, and (*d*) the endometrial glands are straight and proliferating.

During the secretory phase, one finds that (*a*) the coils in the spiral arterioles have increased in number, and they may extend to the upper portion of the functional endometrium; (*b*) collecting venules have increased decidedly in number, especially in the upper portion of the functionalis; (*c*) arteriovenous anastomoses are stated to have increased in number, and (*d*) glands are coiled and secretory, with a rich capillary network about them.

Premenstrually, one finds that (*a*) the spiral arterioles are coiled extensively toward the subepithelial capillary bed, and there are numerous venous and capillary lakes in the subepithelial layer of the endometrium; (*b*) arteriovenous anastomoses are said by Schlegel to be numerous in the vicinity of the terminal branches of the endometrial coiled arterioles; (*c*) collecting veins are of maximum size and number, and (*d*) the capillary bed under the endometrial epithelium is extensive and in general lies with the vessels parallel to the surface.

More A V anastomoses.
Larger veins and venules.
Glands still more coiled.
B. MID-CYCLE
More coils and A-V anastomoses.
Larger Veins and larger Vessels
Glands coiled and secretory
D. Endometrial Thinning.
More coils, stasis, and congestion.
A. EARLY PROLIFERATIVE
Few Coils
Few A-V anastomoses.
Veins small
Glands straight and proliferative
Myo-Endometrial Border

Fig. 3.—Schematic representation of the development throughout the menstrual cycle of an endometrial spiral, or coiled, arteriole, collecting veins, subepithelial venous lakes and arteriovenous anastomoses described by Schlegel. The basal endometrium, which remains relatively unaffected, is indicated below the break in continuity of the endometrium. Based on descriptive data of Schlegel (1945-46),[2] Markee (1946)[10] and Daron (1936).[7]

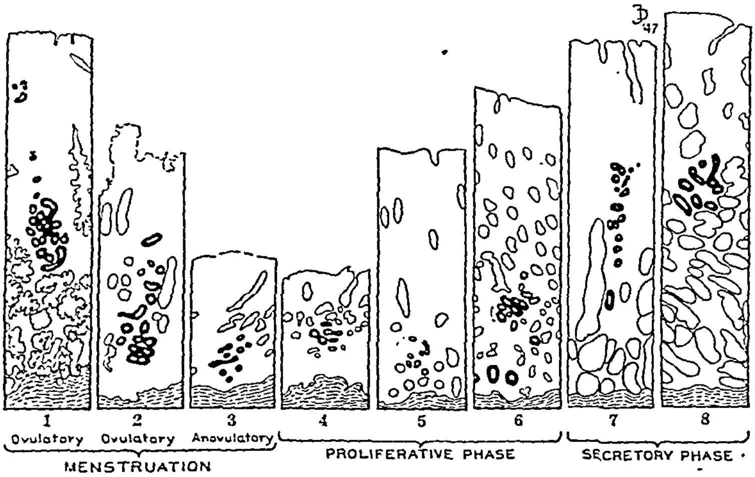

Fig. 4.—Line drawings showing location of endometrial glands and arterioles seen in sections of the endometrial rhesus monkeys. Reduced from camera lucida drawings by Kaiser at a magnification of 25 diameters: (1) first day of menstruation in an ovulatory cycle; (2) second day of menstruation; (3) second day of menstruation in an anovulatory cycle; (4) and (5) early and late proliferative phase; (6) premenstrual endometrium in an anovulatory cycle; (7) midsecretory phase, and (8) premenstrual endometrium, ovulatory cycle.

CYCLIC PHENOMENA AND HORMONAL FACTORS

The relation of cyclic phenomena in the uterus to hormonal factors is a point which has been so frequently and adequately discussed that it will not be treated at length here. It will suffice to indicate this schematically in figure 6. This drawing is based on a similar diagram by Markee (1946). The blood levels and sources of estrogen and progesterone in the blood are shown.[10] The first half of the cycle is associated with rapid growth of the uterine vascular elements under the influence of estrogen. It is a period of tissue repair and proliferation. The groundwork is laid by an increase in the spongy layer of the endometrium for increased coiling of the spiral arterioles later. However, the latter half of the cycle is characterized by secretory activity of the glands and extensive elaboration of the vascular elements that develop in the middle and superficial layers of the endometrium under the influence of estrogen and progesterone, as shown in figure 6.

DEPENDENCE OF UTERINE BLOOD VESSELS ON THE OVARIAN HORMONES

The dependence of the uterine blood vessels on ovarian hormones is a point which requires no elaboration to clinicians. There is a publication by Okkels and Engle (1938),[11] however, which should be familiar to all who are concerned with the problems of menstruation. In short, these investigators have shown that not all uterine blood vessels are equally affected by deprivation of ovarian hormones.

In monkeys extensive fibroelastoid (hyaline) degeneration occurs in response to spaying. The spiral arterioles are much affected, as also are the myometrial radiate arteries and to a less extent the myometrial arcuate arteries. Only the basilar endometrial arteries remain unaffected by deprivation of estrogen, as do the blood vessels of most other parts of the body as far as is now known. These effects are shown schematically in figure 5. This picture also shows that fibroelastoid (hyaline) degeneration may be repaired by appropriate administration of estrogen. Repair requires a long time. Progesterone administered with estrogen has no special effect on maintenance of the fibroelastic tissues of the vascular apparatus in the uterus.

The degenerative vascular changes which have just been described are in response to extreme deprivation of estrogen. Menstruation is the result of a shift in a delicately adjusted balance between growth-promoting stimuli and their withdrawal. What is the nature of these changes?

FUNCTIONAL CHANGES IN THE ENDOMETRIUM DURING MENSTRUATION

The discussion of the functional changes in the endometrium during menstruation will be confined to two points, first, the train of physiologic conditions which leads to menstruation and second, the consequences of a chemical nature in uterine tissues which take place concurrently. Markee (1940)[8] is the primary source of knowledge of the former and Smith and Smith (1947),[12] of the latter. With respect to both points, it is now clear that although the stimulus for growth of uterine blood vessels is blood-borne, the control of menstruation is local.

[11] Okkels, H., and Engle, E. T.: Studies on the Finer Structure of the Uterine Blood Vessels of the Macacus Monkey, Acta path. et microbiol. Scandinav. **15:** 150, 1938.

Markee has advanced the view now widely held that menstruation in the primate uterus takes place whenever there is a period of rapid and sufficiently long regression or thinning of the endometrium. Withdrawal of the stimulus for uterine growth provided by estrogen and progesterone leads to such regression. Rapid regression of the endometrium gives rise to a series of changes prior to, and essential for, menstruation. This involves:

(*a*) Thinning of the mucosa. This is largely attributable to loss of water from the spongiosa.

(*b*) Increased coiling of the spiral vessels. As many as twenty new coils in each arteriole may appear at this juncture, as the elastic elements of the arterioles become shortened when the endometrium becomes thinner.

(*c*) Dilatation of coiled arterioles.

(*d*) Leukocytic infiltration of adjacent tissues and edema in subepithelial tissues.

(*e*) Local necrosis.

(*f*) Local production of a substance which causes intense vasoconstriction of the endometrial blood vessels. This was shown by Markee (1940)[8] who employed endometrial transplants of the monkey into the anterior chamber of the eye. He observed that when there was intense local constriction of the blood vessels in the transplants there was at the same time dilatation of the blood vessels in adjacent parts of the eye. From a variety of such experiments the facts of premenstrual regression (thinning), stasis and localized vasoconstriction have been established.

(*g*) Formation of subepithelial hematomas locally in the endometrium after six to twenty-four hours of vasoconstriction.

(*h*) Necrosis and rupture of the hematomas. Bleeding may last for some twenty-five to seventy minutes.

(*i*) Bleeding as a series of localized hemorrhages with blood escaping in any of several different ways. It may occur as diapedesis; as direct escape from capillaries or arterioles, or as venous hemorrhages. Of these, 22 per cent. of hemorrhages observed by Markee in the monkey were venous hemorrhages. They lasted on the average for forty-seven minutes, in contrast to the other types of bleeding which lasted only a few minutes.

(*j*) Decided slowing in the rate of blood flow in the capillaries.

(*k*) Desquamation of mucosal tissues as a sequel to the intense vascular crisis.

The menstrual process, according to Markee, depends on four essential conditions in the foregoing train of events. These are thinning of the endometrium, increased coiling of the spiral, or coiled, arterioles, hemostasis and intense vasoconstriction. These phenomena have been studied objectively, and no one can doubt their correctness for the rhesus monkey; also, these phenomena on which menstruation depends apply, no doubt, for all other species having endometrial coiled arterioles. There are, nevertheless, two fundamental points which require examination before one can accept this point of view without qualification.

In the first place, Markee's work does not allow for the existence and possible role of arteriovenous anastomoses in the human endometrium. However, Bartelmez maintains that they do not exist in Macacus rhesus (Bartelmez, 1947 [13]). These structures are present, as has been shown, in the superficial layers of the functionalis in the human being in increasing numbers as the menstrual cycle advances. One must also suppose, in agreement with Schlegel (1945-1946),[2] that these structures, if present, are indeed functional and not histologic ornaments. The effect of their activity would be, as with arteriovenous anastomoses elsewhere in the body, to shunt blood away from a peripheral capillary bed. This could conceivably contribute to the initial capillary stasis of menstruation in the superficial part of the endometrium. The presence of extensive venous lakes in the subepithelial portion of the uterine mucosa bears testimony to the fact that venous pressure is relatively high, and the circulation of blood in the capillaries of this area must be decreased accordingly.

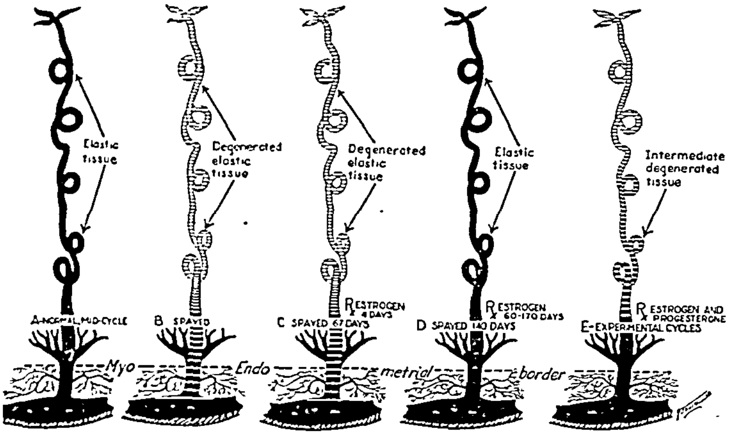

Fig. 5.—Schematic representation of the different susceptibility of the uterine arteries and arterioles to prolonged estrogen deprivation. The cross hatched areas signify fibroelastoid (hyaline degeneration of elastic connective tissue. Note that only the coiled and radiate arteries are affected and that prolonged treatment with estrogen is necessary for restoration of the elastic tissue. Based on the work of Okkels and Engle (1938).[11]

In the second place, the concept of menstruation advanced so effectively by Markee on the basis of his observations in the rhesus monkey neglects the fact that at least three species of New World monkeys possess no spiral, or coiled, arterioles in their endometria (Kaiser, 1947 [4]). Nevertheless, these monkeys manifest microscopic bleeding at periodic intervals (Hamlett, 1939;[14] Goodman and Wislocki, 1935 [15]), and they exhibit periodic desquamation of the endometrium (Goodman and Wislocki, 1935;[15] compare Kaiser, 1947 [4]). These conditions are in accordance with the basic and acceptable definition of menstruation set forth by Bartelmez (1937 [16]), in his article on the mechanism of menstruation, in which he stated: "Menstruation is a bloody discharge associated with necrosis of the uterine mucosa, recurring, in the absence of pregnancy, at intervals of from three and one-half

to five weeks in certain primates." Figure 7 illustrates menstruating endometrium from one of the cebus monkeys described by Kaiser (1947).[4] These tissues are devoid of spiral arterioles, as were those of preparations made from 73 New World monkeys studied by Kaiser (1947).[4] The quantity of tissue desquamated and the amount of blood discharged is undeniably less in New World monkeys than it is in the rhesus monkey and in the human being. This is not, however, a denial of the fact that menstruation does occur in these forms. Rather, it is merely a statement to the effect that the amount of tissue to be shed in order to effect a transition from a secretory to a proliferative endometrium is substantially less in primates without endometrial coiled arterioles than it is in those possessing complex vascular structures in their endometria.[17]

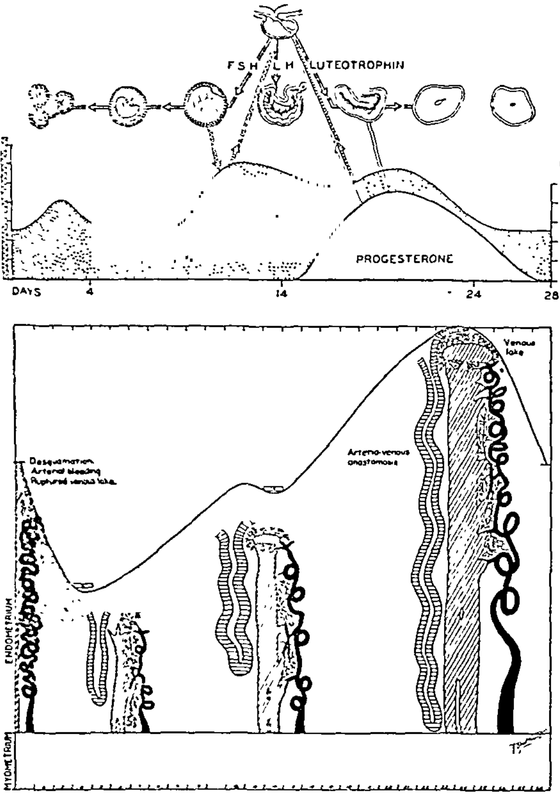

Fig. 6.—Schematic representation of the relation of cyclic vascular changes in the uterus to the chief hormonal factors with which these are associated. Based on a diagram by Markee (1946).[10]

THE MENSTRUAL MECHANISM

The foregoing array of facts affords one a working hypothesis on which to build a concept of the menstrual mechanism. Briefly stated, this is as follows:

1. In the absence of a fertilized ovum, the growth-promoting action of the ovarian hormones on the uterine mucosa is withdrawn.

2. Regression, or thinning of the endometrium, sets in as a consequence of the foregoing hormonal changes. In those forms having no endometrial coiled arterioles, edema and slight desquamation takes place. In those having highly specialized vascular structures in their endometria, reliable investigation has demonstrated the fact that increased coiling of the spiral arterioles occurs as a consequence of withdrawal of the growth stimulus to the endometrium and thinning of this tissue. Altered hemodynamic factors, concerning which no objective facts are available, contribute to capillary stasis, tissue edema and leukocytic infiltration of the tissues. As would result elsewhere in the body when there is ischemia, there occurs in the endometrium local accumulation of the usual products of the degeneration of tissue and protein. Such substances, as Markee observed, proceed to give rise to intense constriction of the endometrial spiral, or coiled, arterioles.

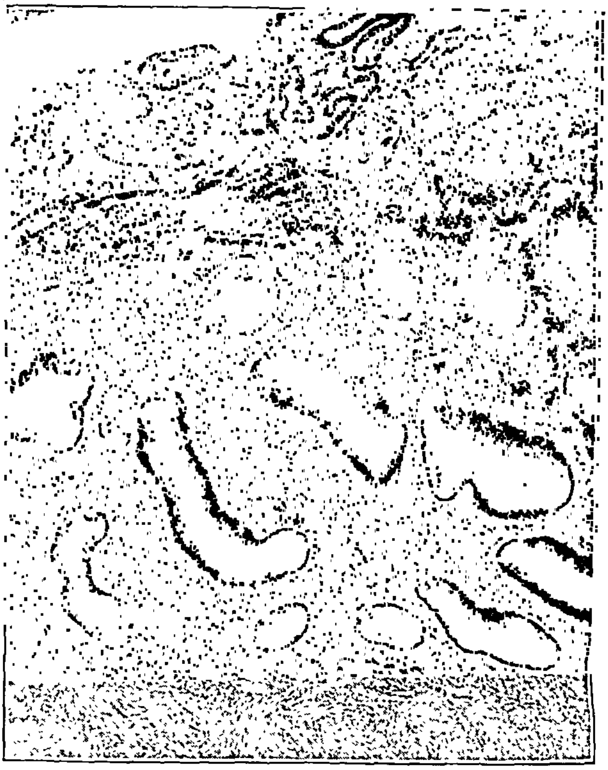

Fig. 7.—Histologic section of endometrium of a New World monkey (cebus) on the first day of menstruation. No spiral or coiled arterioles were present in such endometria; photomicrograph slightly reduced from a magnification of × 60; see Kaiser[4] for details.

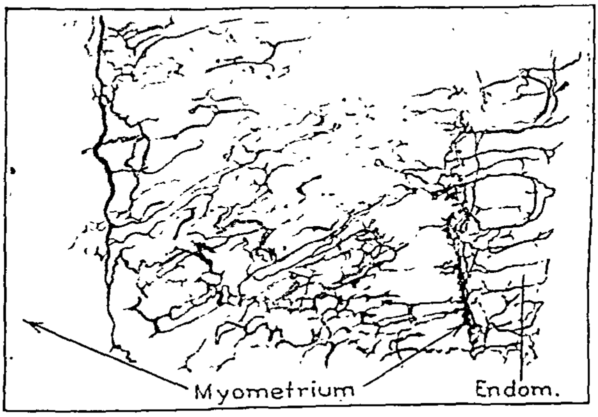

Fig. 8.—Lymphatic network drawn from a reconstruction of serial sections of the uterus of the rhesus monkey. Lymphatics were found in other preparations in the outer zone of the myometrium but never in the superficial fourth (subepithelial portion) of the endometrium. From Wislocki and Dempsey (1939).[18]

---

[17] For discussion of the special case of the gibbon, refer to Kaiser.[4]

In the foregoing concept there exists a situation in which local necrosis must occur. The local circulation is not sustained, there is transudation of fluids, and substances are produced which favor further destruction of the local tissues. Thus in either type of menstruation—that which is not associated with endometrial coiled arterioles or that which is associated with them—there is a deficient mechanism whereby transuded plasma proteins, which are the sine qua non of edema, fail to be removed. This fact suggests, accordingly, that the key to an understanding of menstrual mechanisms lies in a knowledge of the characteristics of the lymphatic drainage of the endometrium. Little is known concerning this topic. The only description available with regard to the distribution of lymphatic vessels within the primate endometrium is that of Wislocki and Dempsey (1939),[18] who have shown that endometrial lymph vessels in a nearly mature rhesus monkey were confined to the bottom three fourths of the endometrium. The superficial fourth of the endometrium was devoid of lymphatic capillaries. This is shown in figure 8. There is, therefore, a morphologic basis for expecting that subepithelial edema with attendant necrosis and desquamation may be associated with a deficient mechanism for removal of plasma proteins from interstitial spaces. Thus this may be the key functional point around which menstruation revolves. Clearly, more work should be done to test the validity of such an assumption.

A MENSTRUAL TOXIN?

In conclusion, reference must be made to the important work of Smith and Smith (1947)[12] on the subject of a so-called menstrual toxin. These investigators have established that a substance is contained in menstrual discharge which is highly toxic when injected into rats. It kills them within twenty-four hours.

This active substance in menstrual discharge is a euglobulin. It is found in greatest concentration in the cellular debris fraction of menstrual centrifugate. It is present in highest concentration in early menstruation but diminishes in amount as the quantity of menstrual discharge increases. The toxin has been found in fresh endometrium prior to the onset of actual bleeding, although it is not present at other times in the menstrual cycle. It is present whether the cycle has been ovulatory or anovulatory.

There is no question concerning the validity of the foregoing facts. They have been established by objective tests. There are two reservations, however, which must be made in connection with them. First, the precepts of sound logic require that one refrain from stating that this toxin is the cause of the onset of menstruation. It has been seen that menstruation is the result of a series of integrated effects resulting from the special structural and functional features found within the endometrium. Second, if the euglobulin which Smith and Smith have demonstrated to be present in menstrual discharge is in fact related to the intense vasoconstriction which Markee has shown to be part of the whole process, then it might well be called something other than a toxin, since it subserves a physiologic role during the sex cycle.

MENOMETRORRHAGIA DURING ADOLESCENCE

C. F. FLUHMANN, M.D.
San Francisco

Any consideration of menometrorrhagia during adolescence and conditions associated with this age group requires that attention be directed to distinguishing between the terms adolescence, menarche, puberty and maturity, because they have been employed loosely and invariably as being synonymous. Adolescence has been defined as "the process or condition of growing up . . . the period between childhood and maturity." It therefore includes the latter part of the growth period and the transition to complete somatic and sexual maturity. During this time there are important changes in the organs of internal secretion, a gradual cessation of increase in stature, a psychic transformation and the acquisition of the secondary sexual characters. The appearance of the first menstruation, the menarche, normally is one of the most important events of this epoch and is readily recognized, but it is not the end point of these various processes. On the other hand, maturity implies that the young woman has attained the completion of somatic growth and has acquired the capability of bearing children. It usually is reached some years after the menarche. The word puberty is still more confusing, as it has received many definitions, some, unfortunately, with the assistance of sentimental popular novelists. It would be desirable to drop the word puberty from medical literature unless it is limited and generally accepted as referring to some definite period. One suggestion is to limit the term to the months or years which extend from the menarche to maturity.

ABNORMAL UTERINE BLEEDING

It is most unfortunate that such terms as puberty bleeding and menopausal bleeding are in constant usage, since they are actually nonentities. There is no such thing as puberty bleeding or adolescent bleeding, since there is no single specific factor concerned; the terms merely serve as a clue to the age of the patient or patients concerned. It is important to remember that any of the various causes which lead to abnormal uterine hemorrhage may be effective at any time from the menarche to the menopause. Instances have been reported of bleeding during adolescence from fibromyomata uteri, adenomyoma, inflammatory lesions of the pelvic organs, incomplete abortion, systemic diseases, such as purpura hemorrhagica, and endocrine dyscrasias. Pollock and Taylor [1] found in the literature 30 cases of cancer of the cervix uteri occurring during the first two decades and added 1 of their own. Traina-Rao and Pesce [2] in a series of patients with cancer of the cervix observed that the youngest was 14 years of age and that 0.14 per cent were from 10 to 20 years of age.

Although there is no single specific causative factor for menorrhagia or metrorrhagia during adolescence there is a definite relationship between the etiologic

factors and the frequency of their occurrence. It is of importance to be aware of the different lesions just mentioned, but at this age period they are unusual events; in the vast majority of instances the bleeding stems from the nature of the early menstrual cycles and the existence of an endocrine disorder which leads to hyperplasia endometrii.

EARLY MENSTRUAL CYCLES

The appearance of the first episode of cyclic uterine bleeding does not necessarily mean that menstruation with a complete ovarian cycle has become established. As Hartman[3] has stated, "there is a gradual process as the adolescent female gets her stride, as it were, in the matter of her menstrual regularity and the sexual cycle in general." This feature is demonstrated clinically by the fact that the early cycles are particularly prone to be irregular, with frequent periods of amenorrhea and at times profuse and prolonged menstruation. For the first few years, in spite of the occasional occurrence of gestation in young girls, there is also a relative sterility (Hartman[3]). With child marriages of India cohabitation begins at the menarche, but it is stated that usually the first child is not born until the third year of effective marriage. It is remarkable also that among peoples such as the Trobriand islanders and the Igorots and Bontoks of the Philippine Islands, pregnancy in young unmarried girls is extremely rare despite the absolutely unrestrained and promiscuous sex life which begins in childhood.

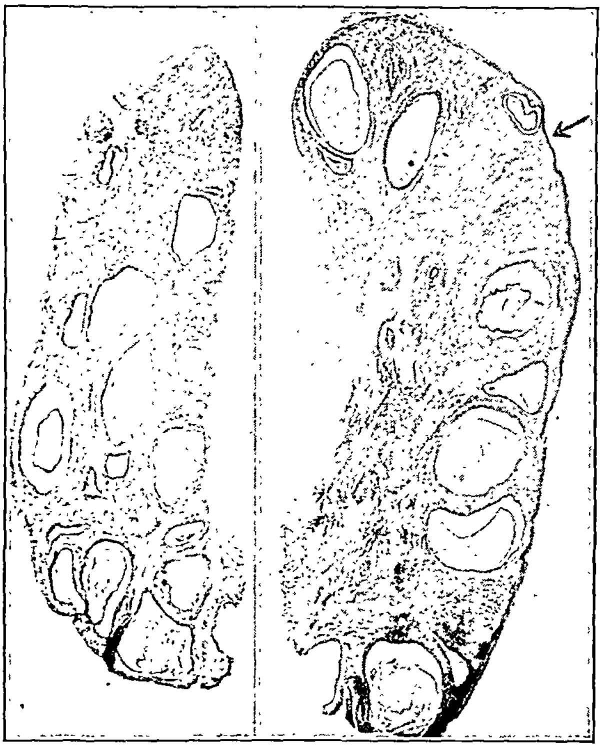

Fig. 1.—Degenerating corpus luteum (arrow) in ovary of a girl aged 12 who died of a cerebral hemorrhage. The opposite ovary shows only atretic follicles. *She had had four menstrual periods and this is offered as evidence that ovulation occurred only once during this time.* After Laqueur.[10]

These observations are associated with the occurrence of a preponderance of anovulatory cycles at this age period. At such times cyclic uterine bleeding is present but ovulation does not take place; the ovaries do not contain an active corpus luteum, and the endometrium is in the stage of proliferation observed after estrogenic stimulation. The incidence of such cycles was first demonstrated in the Macacus rhesus monkey by Corner,[4] Hartman[3] and Edgar Allen,[5] but evidence has accumulated to show that these cycles are also found in the human subject (Corner,[6] Bartelmez,[7] Mazer and Ziserman[8] and Novak.[9] An excellent example is the case recently reported by Laqueur[10] of a girl aged 12 who died after a spontaneous intracerebral hemorrhage. She had had four menstrual periods immediately prior to her death, and examination of the ovaries showed the presence of only one degenerating corpus luteum, thus indicating that ovulation had occurred only once (fig. 1).

HYPERPLASIA ENDOMETRII

The most frequent cause of unduly prolonged or profuse cyclic and acyclic uterine bleeding which may occur during both early and late menstrual life is an endocrine disturbance of a somewhat obscure origin. In this country it is generally referred to by the name applied to the histologic appearance of the endometrium, namely, hyperplasia endometrii, and all attempts to give it some connotation referring to a systemic endocrine disturbance, such as metropathia hemorrhagica, have failed to gain general acceptance. Nevertheless, this disorder must be recognized as the most important but not the sole factor producing pathologic uterine bleeding in the postmenarcheal and premenopausal periods of life.

Although one is tempted to draw comparisons between anovulatory menstruation and hyperplasia endometrii there are such distinct differences between the two, both clinically and in the histopathologic observations in the endometrium, that the latter must be considered as a separate pathologic entity. It is unfortunate that it does not occur spontaneously in monkeys, as the anatomists possibly could give much assistance, but the best they have offered so far is to reproduce a similar lesion by the use of massive doses of estrogenic hormones in castrates.

During the postmenarcheal period hyperplasia endometrii manifests itself by abnormal uterine bleeding. Usually it appears as cyclic bleeding occurring at longer or shorter intervals, and not only is it extremely profuse but it may persist for many days longer than average menstrual periods. At times the bleeding follows amenorrhea of many weeks' or months' duration. In still other instances the flow is slight but continuous over long periods of time. It is important to note that the bleeding in these cases is not accompanied by pain, while the occurrence of dysmenorrhea is generally associated with ovulatory cycles.

The clinical examination of patients with hyperplasia endometrii does not usually bring to light any significant observations. The development of the secondary sexual characters is invariably complete; there is no characteristic pattern as to stature or weight, nor are there endocrine stigmas. Rectal or vaginal examination may reveal a slightly enlarged and soft uterus, but this observation at this age is not constant.[11] Often there is a lowering of the basal metabolic rate, but other laboratory investigations offer no assistance except for the low blood count which naturally accompanies the anemia produced by the frequent hemorrhages.

[10] Laqueur, G. L.: Anatomical Demonstration of the Anovulatory Menstrual Cycle, California & West. Med. **63**: 268 (Dec.) 1945.

The pathologic changes in the endometrium and the ovaries have been the subject of many studies since those of Robert in 1846, Olshausen in 1875, Bischoff in 1878, Brennecke in 1882 and Cullen in 1900. In more recent times concepts have been based on the work of Schroeder [12] in 1915 and Meyer [13] in 1920, followed by that of a host of investigators, to mention only a few, Novak, Seitz, Shaw, Fluhmann, Tietze, Burch, Jeffcoate and Payne.

The ovaries are sometimes slightly enlarged and may be palpable. On histologic examination their appearance is strongly reminiscent of that observed in women who have had a number of anovulatory cycles such as in the case reported by Laqueur.[10] The most characteristic feature is the absence of active corpora lutea, and in instances of long standing there is no evidence of recent ovulation. The ovaries contain graafian follicles in various stages of development, some with well preserved granulosal and thecal layers but mostly showing all stages of atresia. Since each gonad may display as many as ten to thirty cysts of this type the general picture conforms with the classic description of "cystic degeneration of the ovaries."

It is in the endometrium, however, that one must look for the striking manifestations of this disease. The endometrium grossly is likely to be thickened and edematous, and large amounts of tissue may be obtained on curettage. The final diagnosis is made on histologic examination, and I consider that a differentiation must be made on whether the specimen is obtained at a time when the patient is in a quiescent stage or actually bleeding. The stroma is dense and cellular, the cells are spindle shaped, and active proliferation is evidenced by numerous mitotic figures. The presence of many large blood vessels is a prominent feature, and in some instances there are decidedly dilated veins under the surface epithelium. There are several types of glands which are arranged in a totally disorderly fashion. First, there are glands with a single layer of cylindric epithelium, identical with those normally found during the stage of proliferation. Second, glands with stratified epithelium reflect the pronounced growth activity so characteristic of this disease and at times make one suspect the existence of cancer. Third, cystic glands lined with a low cuboidal epithelium are an important characteristic, and the gross appearance which they impart to the uterine mucosa led Novak to refer to a "Swiss-cheeze" pattern of this lesion. Whenever the specimen of endometrium is obtained while the patient is actually bleeding additional features are observed, namely, areas of necrosis with thrombosis of neighboring blood vessels and an extensive infiltration with leukocytes.

The actual cause of hyperplasia is not known, although it has been suggested that it may result from a disordered anterior hypophysial activity characterized by the production of excessive amounts of the follicle-stimulating hormone and diminished or absent formation of the luteinizing factor. At any rate, there is ample evidence that the endometrial picture is due to estrogenic stimulation in the absence of the corpus luteum factor. It was once thought that it was the direct result of an overproduction of estrogen, and the term hyperestrinism was coined (Fluhmann [14]). However, studies of the estrogenic content of blood have failed to substantiate this theory. In fact, the blood of many patients during the nonbleeding phase manifests a low estrogen content, and there even may be a cycle in its production (Fluhmann [15]). It is of special interest that some women have shown a gradual increase in the amount of estrogen demonstrable just before the onset of a hemorrhagic episode (*fig.* 2), and with the subsidence of the bleeding there has been a corresponding drop in the hormone level (Fluhmann [16]).

When hyperplasia endometrii occurs in young women it is essentially a self limited disease, and ovulation with a restoration of normal menses is to be anticipated. Of 15 juvenile patients observed over many years Klingelhöfer [17] found that only 3 gave any evidence of ovarian disturbance in later life. However, it is of importance to remember that hyperplasia may persist for many months or years, during which time the patient should be under constant surveillance.

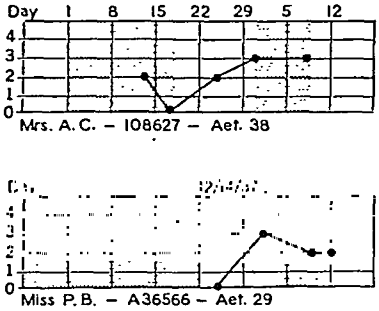

Fig. 2.—Rise in the blood estrogen level with the onset of a hemorrhagic episode in hyperplasia of the endometrium. (Fluhmann [15]).

The treatment should have two aims. First, any anemia resulting from the hemorrhage must be combated with suitable medicaments containing iron, and it may even be necessary to resort to blood transfusions. Second, attempts should be made to control the bleeding, and in adolescent girls the methods at present in vogue are in the main endocrine measures. However, when the diagnosis is obscure, or in occasional intractable cases, a curettage is indicated and may be repeated. A hysterectomy is only resorted to in extremis, and the only instances I know in which it has been performed have been in patients neglected for long periods of time. Although still advocated by some physicians I am opposed to irradiation either with roentgen rays or radium, even at small dosages, because of possible injury to the ovaries and potential harm to the germ plasm, which may manifest itself in the offspring of the second or later generations.

---

[11] In extremely infrequent instances the lesion is a direct result of a granulosa cell tumor of the ovary, which may be palpable.

Of the endocrine preparations of value thyroid extract still remains the most valuable in patients with low basal metabolic rates, and it should be administered to the point of tolerance. Its usage in the absence of any evidence of hypothyroidism is definitely open to question. The anterior pituitary preparations available today are of no value and in some instances appear to intensify the episodes of bleeding. Chorionic gonadotropin long has been recommended, but its employment has been abandoned by most authorities. If it is used it must be given at a time when bleeding is present and at large dosages, such as 1,000 or 2,000 international units a day.

It is remarkable that large doses of either estrogen or progesterone are extremely effective in the control of the bleeding. Their employment over several months for a few days at the start of each bleeding period may also prove of curative value, but the importance of large dosages at such times cannot be overemphasized. Karnaky[18] first advocated the employment of diethylstilbestrol for this purpose, but the nausea and vomiting which this substance often induces is a considerable disadvantage. However, the natural estrogens may be used provided adequate dosages are supplied (for example, 20,000 units of estrone daily or 2.5 mg. estradiol dipropionate or 3.0 mg. estradiol benzoate). Progesterone is used in a similar way and is given at dosages of 10 mg. daily intramuscularly for four or five days. Pregneninolone is also valuable, but 40 to 50 mg. must be taken orally for from five to ten days. Either of these preparations invariably lead to a rapid cessation of the bleeding, but some six or ten days later a moderate flow for a few days often occurs, and the patient must be warned of this possibility. If it does not become protracted no treatment is indicated. The explanation for this secondary bleeding is that a stage of secretion has been superimposed on the hyperplastic endometrium and an artificial menstruation has been produced. Since this results in a desquamation of the endometrium Jones and Te Linde[19] refer to this treatment as inducing a "medical curettage." Although the androgens have a place in functional bleeding in older women they are contraindicated in this age group because of the adverse effects which may result from prolonged treatment.

SUMMARY

Abnormal uterine bleeding is of frequent occurrence during the years immediately following the menarche and may result from any of the lesions found during active sexual life. The most frequent cause, however, is the incomplete ovarian function characteristic of this age period and the endocrine disorder known as hyperplasia of the endometrium. The clinical history, diagnosis and treatment of hyperplasia endometrii are given.

FUNCTIONAL BLEEDING

ARTHUR H. CURTIS, M.D.
Chicago

Definition.—Functional bleeding is loss of blood from the uterus without demonstrable pathologic cause. The term must include normal menstruation. No amount of logic or argument can confute that statement, despite the fact that physicians all prefer to limit the meaning of the term functional bleeding to abnormal loss of blood. A satisfactory explanation of the physiologic basis of normal menstruation, although not yet complete in some essentials, must serve as a basis for adequate understanding of menstrual abnormalities.

In common parlance, functional bleeding includes all cases of excessive uterine flow ascribable to endocrinopathic disturbances except those in which there are tumors of the endocrine glands. It does not include bleeding caused by high blood pressure, blood dyscrasias and other recognizable systemic affections.

Special Factors in Abnormal Functional Bleeding.—In consideration of the causes of abnormal functional bleeding, I shall not elaborate on the accepted belief that pituitary or hypothalamic dysfunction may cause bleeding through excessive stimulation or inadequate control of ovarian activity, particularly in the elaboration of estrogen; nor need I emphasize that bleeding may occur because of failure of the ovary to respond to pituitary gonadotropic stimulation. That fluctuation in the estrogen level, rather than hyperestrinism or prolonged uninterrupted action of estrogen, is responsible for bleeding is common knowledge.

Absence of ovulation with consequent deprivation of progesterone is common during adolescence and during the period of waning ovarian activity at the menopause. At these times without ovulation the uninterrupted action of estrogen tends to be rather self limited: there is almost never endangering menopausal bleeding from this factor alone, but during adolescence the functional flow may be serious.

Although abnormalities of the hormonal rhythm during adolescence and at the menopause are well known, it is apparently not recognized that menorrhagia tends also to occur at the time when ovarian activity begins to falter, usually at an age of from 36 to 38 years. To this last-named period I apply the term "little menopause." Menorrhagia at this time affects particularly those who have led lives of frustration, sexually or otherwise; those with lesser endocrine disturbances; those with endocervicitis, and those with a familial history of menorrhagia.

Intractable bleeding of the menopause, sufficient to demand intervention, is seldom purely functional. Persistent profuse flow bespeaks a pathologic condition, often small myomas which elude identification and are recognized only on palpation with the patient under anesthesia or on dilatation and curettage or on opening the uterus after hysterectomy.

The aim of this article is to assess all practical information pertinent to functional bleeding. Therefore, at this juncture I am impelled to pause for a moment to consider one affection—high blood pressure—in

relation to postmenopausal uterine bleeding. I was surprised at a statement made recently in Chicago,[1] that high blood pressure is not a cause of uterine bleeding, for I have seen many instances of otherwise inexplicable hemorrhage after the menopause in which a pressure of 185 mm. of mercury or more has been the only demonstrable lesion.

Diagnosis.—For clinical purposes, let me evaluate those measures which are of assistance in making an accurate diagnosis of the cause of bleeding and devaluate those which are chiefly of academic interest:

A pelvic examination should include rectovaginal palpation, for the latter gives much more accurate information than does vaginal examination alone.

I am impressed that special endocrine studies are not necessary in the diagnosis of functional bleeding and that diagnostic curettage is required chiefly for recognition of tumors, particularly cancer.

Estrogenic therapy has completely disoriented the medical appraisal of menopausal bleeding: Smears from those who have received enough estrogen to produce bleeding often reveal evidence of cellular activity suggestive of cancer; the uterine curettings may yield patterns simulating adenocarcinoma enough to confuse even an experienced pathologist; the increase in induration, bulk and weight of the uterus is often deceptive. In view of all these factors in bleeding patients who have been receiving estrogenic therapy, discontinuance of the medicament and expectant care for three weeks or more is preferable to immediate diagnostic intervention with unqualified interpretation of the evidence.

Since the advent of "dicumarol" it has been observed that salicylates also have a tendency to produce hemorrhage. Routine inquiry about the amount of acetylsalicylic acid taken by patients who consult the physician for vesical or uterine bleeding permits an occasional diagnosis of otherwise inexplicable functional bleeding.

Elimination of the Hazard of Cancer.—Vaginal smears to rule out otherwise undetectable cancer are an asset, but I must emphasize that the dependability of skilled examination of cervical and vaginal smears in search for evidence of uterine cancer has been overstressed. For example, metaplasia of the cervical epithelium is of common incidence, and isolated cells or groups of cells sloughed from the metaplastic cervix may defy differentiation from malignant cells. This is particularly true if the patient has received estrogenic therapy.

Cervical biopsy for elimination of cancer is a diagnostic asset. Failure to remove a specimen for biopsy preliminary to office cauterization of a dubious cervical lesion is unwise.

TREATMENT

Therapeutic Curettage.—The percentage of cures incident to therapeutic curettage varies directly with the frequency with which one resorts to this procedure. The majority of patients with functional bleeding recover spontaneously; if one curets only those with intractable bleeding, the prospect of relief is scarcely worth the expense of hospitalization unless the procedure is indicated also to determine whether there is a submucous tumor or a malignant growth. To my mind therapeutic curettage in the earlier stages of functional bleeding is in a measure comparable with curettage after spontaneous abortion, which is often a race to determine whether the physician can get the patient to the hospital before bleeding ceases.

Hemostatic Therapy.—My experience with ergot preparations is that they are of limited value in hemostasis. Vitamins B, C (ascorbic acid) and K are in an experimental stage. Commonly accepted measures for the control of anemia require no discussion here.

Radiation Therapy.—Treatment by radiation has lost much of its appeal except in the care of cancer, but surely it merits a permanent place in the therapy of menopausal bleeding, irrespective of whether myomas of small size are present. Preliminary curettage is essential.

Hormonal Therapy.—The value of thyroid medication in selected cases of functional bleeding is widely accepted and requires no further comment.

At no time in the history of gynecology has there been so much confusion regarding other hormonal therapy. If sex hormones are to be employed, some divergence of opinion centers about whether estrogens or androgens are preferable. In evaluation of the rather widespread belief that male hormones are unnatural and harmful to women, certain facts merit mention: Androgens are produced, are metabolized and are excreted by the normal woman. Almost as much androgen is found in the urine of the normal human female as in that of the male. The hazard of masculinization from judicious androgenic therapy has been overstressed.

Prior to further elucidation of the physiology of the sex hormones and more satisfactory demonstration of the efficacy of specific products, I have found it preferable to avoid substances, notably estrogens, which tend to increase the size and activity of the uterus and endometrium. It is known that testosterone inhibits pituitary gonadotropic activity and that it has a direct inhibiting effect on the uterine musculature. And, in any event, it controls bleeding and accomplishes it without producing palpable enlargement of the uterus and hypertrophy of the endometrium.

The routine procedure is the administration of three 10 mg. tablets of methyltestosterone a day when there is free bleeding and two a day when there is moderate bleeding, but none when there is slight flow. It is preferable to allow the tablets to melt in the mouth, for absorption into the circulatory system increases the efficacy of testosterone. In those unusual instances in which methyltestosterone fails to afford satisfactory control of the bleeding, one may give additional intramuscular injections of 25 mg. of testosterone every second day until the flow ceases.

Androgenic therapy is not a specific cure. However, it inhibits bleeding, month after month, usually until the menorrhagia-provoking mechanism has reverted to normal or, sometimes, until a pathologic cause of the bleeding becomes evident.

SUMMARY

1. The nature and causes of abnormal functional bleeding remain undetermined, although less problematic than heretofore.

2. Treatment of abnormal functional bleeding is largely symptomatic and empiric. Hormonal therapy is confused and in a state of flux but fairly satisfactory.

BLEEDING ASSOCIATED WITH THE MENOPAUSE

J. P. PRATT, M.D.
Detroit

Rhythmic bleeding over a period of years is a habit that is accepted. Any variation of duration in rhythm or amount of bleeding causes anxiety to the patient and obligates the physician to find a satisfactory explanation. Cancer education has taught many more women to be aware of irregular bleeding and has induced them to seek professional advice, thereby increasing the opportunity for early diagnosis of cancer. While cancer is the most important cause of menopausal bleeding, many other conditions are to be considered.

The average age at the menopause is about 47, but it may appear years earlier or later. Since cyclic activity of the uterus depends on ovarian function, the menopause is really an expression of the state of the ovaries. The peak of ovarian activity is reached at about the age of 25. From that time there is a gradual decrease of ovarian function until a level is reached that is too low to induce menstrual flow. Hence, the premenopause might be said to begin at 25 years of age.

Normal cessation of menstruation at the menopause varies in different persons, and sudden cessation of flow is not the most commonly observed form. For a few months or years preceding the menopause there may be an increase in the amount or frequency of flow. In such instances the interval must be regular and not less than two weeks to be considered normal. To place a limit on the amount of flow that is normal is more difficult, but much will depend on the patient's previous record; e. g. heavy flow appearing in a woman who previously had scant flow should arouse suspicion. A gradual decrease in the amount or frequency of flow is usually not a cause for concern.

Uterine bleeding may be a symptom of anatomic lesions, or it may occur without any structural change being demonstrable. Physiologic disorders may appear without any evident structural basis, or bleeding may be associated with but not dependent on anatomic lesions. Interpretation of the cause of bleeding, therefore, requires a careful search for a lesion which might explain the symptom. If no lesion is found, disturbance of function is assumed; then a thorough survey of the patient for systemic disease and glandular disorders is indicated.

When a problem of uterine bleeding is presented, many conditions may enter into the differential diagnosis. Some of these may now be briefly mentioned:

1. Hyperplasia of the endometrium may occur at any time during the reproductive period, at the menopause or even long after the menstrual flow has ceased. At any period of life the mechanism is the same—an abnormally persistent and relatively excessive estrogenic influence, producing growth of the endometrium. Bleeding of the hyperplastic endometrium may be explained by the same process of vascular changes as that which occurs in menstruation, but the growth of endometrium and the amount of bleeding are not proportional to the excess of estrogen. Diagnosis is made by history and curettage. Ribbons of tissue as well as the amount of tissue removed by a curet are suggestive. Microscopic examination is usually conclusive, but in some instances it is exceedingly difficult to distinguish between benign adenoma, adenocarcinoma and hyperplasia. In some instances the diagnostic curettage alone is adequate treatment. If the bleeding persists, the relative merits of irradiation (to reduce ovarian function) or hysterectomy are to be considered. Hormonal therapy may be tried, but since any type of endometrium may bleed and since the amount of bleeding is not proportional to the excess of estrogen, choice of the hormone to be used remains problematic.

2. Cervical polyps are frequent in women after the age of 40. These growths may be present for a long time without symptoms. Bleeding, the chief symptom, may be an increase of the menstrual flow or slight spotting between the periods. Postcoital staining may be noted, and occasionally a severe hemorrhage occurs. Although polyps are usually benign, diagnosis of them is important, for the symptoms may simulate those of cancer. Most polyps can be seen and felt, for their presence causes dilatation of the external os. Unusual patency of the os should arouse suspicion that a cervical polyp exists. Growth of a hidden polyp may frequently be stimulated by estrogenic therapy, thus facilitating its detection. The majority of cervical polyps are pedunculated and can be diagnosed macroscopically. Sessile polyps require microscopic analysis. Treatment of cervical polyps is excision, and when they are pedunculated it is a temptation to remove them at the time of the examination in the office. However, it is better to curet the uterus and cervical canal, for other lesions may be present.

3. Endometrial polyps present similar problems of bleeding. Diagnosis may be suggested by the symptoms, but final proof rests on their removal.

4. Adenomyosis of the uterus in women past the age of 40 is a cause of hemorrhage which is often extensive. Treatment is either reduction of ovarian function or hysterectomy. If artificial menopause has been established, the use of estrogens for menopausal symptoms is contraindicated because the bleeding might recur.

5. Fibromyomas of the uterus, particularly in the submucous location, tend to produce a more profuse and prolonged flow and to shorten the intermenstrual interval. When the tumors protrude into the uterine cavity and become polypoid, necrosis with infection may occur with symptoms of intermenstrual bleeding and foul discharge, thus simulating cancer.

6. Functioning tumors of the ovary occur from childhood to old age, but the majority are found after middle life. In the postmenopausal patient the estrogen-producing function of the feminizing tumors stimulates the uterus, producing renewed growth of the myometrium and endometrium. Atypical bleeding occurs, which may be cyclic or regular, scanty or profuse. The presence of an ovarian tumor with renewed bleeding is significant.

7. Vascular changes are accepted as normal for the menopause. As the ovarian function diminishes, the blood vessels of the uterus shrink and show varying degrees of arteriosclerosis. Occasionally a sclerotic vessel ruptures, giving rise to more or less serious hemorrhage. I recall 1 such instance in which the

patient bled profusely, requiring transfusion before she could be moved from her home to the hospital for hysterectomy. Examination of the uterus revealed a single rupture in a sclerotic artery. Her vascular system did not manifest generalized arteriosclerosis.

8. Inflammations of the ovary or uterus are associated with menorrhagias during the earlier years of the reproductive period. The same conditions may persist up to the menopause but cannot be considered characteristic of this period in life. There are certain inflammatory lesions, however, associated with involution; e. g., senile vaginitis. As the estrogenic stimulation diminishes, the vaginal mucosa is reduced in thickness and the blood vessels come to lie close to the surface, giving a characteristic reddish appearance. The smooth surface is easily abraded and often becomes infected. Opposing surfaces may heal together even to the point of obliteration of the upper part of the vagina. The discharge from infected areas and from breaking adhesions is often blood-tinged. Occasionally the bleeding may be profuse.

9. During the process of involution the mucosa may contract about the external urinary meatus with eversion of the urethral mucosa. This delicate tissue is susceptible to injury and may also become infected. Blood stains may be noted either from injury or from infection.

10. Prolapse of the cervix exposes it to injury which may lead to abrasion or even ulceration. The cause of bleeding is obvious on inspection.

11. Stenosis of the cervix is a part of the genital atrophy of involution. As the occlusion of the cervix progresses, secretions of the endometrium may be retained. Bacteria invade the cavity through the partly occluded cervix, and endometritis may result with retention of pus—pyometra. Sometimes the pressure within the uterus reaches a point at which the purulent content is expelled; at other times the occlusion of the cervical canal may be complete, and the infectious process may be isolated in the uterus. It is believed that seepage of the irritating material from the uterus may be a cause of senile vaginitis. The alternate retention and drainage of the uterus has been known to go on for years.

12. Therapeutic bleeding is an innovation of recent years, and it is gaining in significance. Since the discovery of potent estrogens and synthetic preparations with estrogenic activity, estrogenic therapy has expanded tremendously. Even the injection of natural estrogens is no longer exclusively an office practice, for patients have been taught to treat themselves. For the most part, however, hypodermic injections remain in the hands of physicians or office nurses. With the introduction of synthetic preparations, diethylstilbestrol and related compounds, self medication is increasing rapidly, especially since the material can be purchased over the counter without prescription. Cyclic bleeding can be demonstrated in women long past the menopause by the administration of estrogens. Bleeding can be controlled and timed by planning the dose and time of administration. In many instances bleeding occurs when medication is continued at the same level without interruption. Formerly, one expected to find an organic lesion in nearly every instance of bleeding after the menopause. This is by no means true today. Analysis of the cause of premenopausal bleeding is far more difficult than it was before the use of estrogens. It has become necessary in every investigation of menopausal bleeding to determine, if possible, whether the patient has been using estrogens. Correct information regarding the material used or the dosage is often difficult to obtain. In many instances the chief gynecologic complaint is therapeutic bleeding. Emotional disturbance may be important on account of fear of cancer. Judicious use of estrogens is desirable, but thoughtful consideration should be given to the indication for prescribing them and self medication should be discouraged.

13. Carcinoma ranks first in importance among all the causes of menopausal bleeding. It is a murderous disease with an insidious onset. Hope of improving the cure rests on earlier detection of the lesion. Since almost every carcinoma of the uterus, tubes or vagina bleeds, and in many instances bleeding is an early symptom, it is axiomatic that correct interpretation of every instance of menopausal bleeding would expose the brutal invader.

Bleeding appears relatively earlier in cancer of the fundus than in that of the cervix. Nearly every cancer of the fundus bleeds early. The diagnosis may be confused by the presence of fibroids, and because the fibroids are easily felt the possibility of coexisting carcinoma may be overlooked. If irradiation is contemplated for a fibroid tumor, the possibility of cancer should be borne in mind and a thorough curettage of the uterine cavity should be performed. Even then it is possible to miss a malignant growth. Cytologic study of exfoliated cancer cells found in vaginal smears is a valuable contribution to early diagnosis. Desquamation of epithelial cells from a malignant growth is greater than from normal epithelium. Its designation as a prebiopsy method of detection is well justified.

Cancer of the cervix is treacherous because symptoms of the early stage are absent or negligible. The first symptom is leukorrhea, which is an increase of normal secretions due to hyperemia, differing from the normal only in quantity. The local blood vessels, changed by the new growth, become more permeable; plasma exudes, and the leukorrhea becomes watery. Unfortunately, this early symptom is seldom recognized. Later the small blood vessels are broken by the invasion of the growth, and traces of blood are noted particularly after coitus or following a douche. Cancer education has helped to make more women conscious of trivial bleeding. Cancer detection has disclosed many carcinomas of the cervix before appreciable symptoms appear.

14. Other miscellaneous causes of menopausal bleeding include systemic disease, endocrine disorders, particularly thyroid, nutritional disturbances, vitamin deficiencies and inorganic deficiencies, particularly calcium.

Cancer education has unquestionably made many women cancer conscious. Sometimes this is unfavorable, for it may cause profound emotional disturbances from an unfounded cancerphobia. Many women complain of bizarre symptoms that are not explained by physical observations. It has been my practice, when no objective signs are present, to remark casually, "At any rate, you know that you do not have cancer." Frequently, the patient then says, "Doctor, that is what I really wanted to know." A real opportunity for giving comfort would be missed if one did not recognize the possibility of the patient's repression and fear to ask.

Menopausal bleeding is an important subject with many ramifications. Some of the numerous causes of bleeding have been mentioned. In each instance careful consideration of the patient as a whole is demanded. An honest effort should be made to find the true cause. Women should be encouraged to seek an explanation of every bleeding, no matter how trivial. This field offers the physician a great opportunity for giving comfort and saving life.

PANEL DISCUSSION

Arthur H. Curtis, M.D., Chicago, Moderator

The Moderator: In Dr. Fluhmann's absence due to illness in his family I shall ask Dr. Emil Novak, of Baltimore, to answer questions for us.

HYPERESTRINISM

Question: Is equine gonadotropin used to induce ovulation in hyperestrinism?

Dr. Emil Nowak, Baltimore: Practically all of the methods of ovarian therapy used in the treatment of functional bleeding only scratch the surface. They are directed toward the ovarian manifestation of a disturbance which is surely primarily pituitary. Dr. Fluhmann and others have emphasized in this symposium that at the bottom of this disorder is a failure of ovulation, an incomplete ovulatory cycle. If we could give the pituitary principle, equine or not, which would invariably and precisely induce ovulation, we could cure most of these patients of this particular group that we are discussing. Unfortunately, we have in gonadotropin no principle of undoubted virtue. Some years ago an article was published by two excellent gynecologists in Chicago. The belief was expressed that by giving equine gonadotropic hormone it would be possible to induce ovulation in human beings. They are now quite willing to admit the incorrectness of this. No one has as yet devised any way of making a nonovulating woman ovulate. All our present day methods of treating functional bleeding are pretty much in the nature of makeshifts. They are stopgaps, but we have to use them in women with severe and perhaps intractable bleeding. It is not altogether physiologic, perhaps, to give large doses of estrogen for the cessation of bleeding, but it does the work in a great many cases. It probably is not entirely physiologic to give a woman with decompensation digitalis, but it does the work, and we have to treat these women as sick women. The same applies to the estrogenic hormone, concerning which I feel pretty much the same as Dr. Curtis. It is not as unphysiologic, perhaps, as it may seem, but even if it were, if it tides them over until the hoped-for readjustment takes place—as it does in almost all cases—there certainly can be no criticism, especially since we have no ideal method of treatment based on the physiologic disturbance which takes place in these cases.

UTERINE BLEEDING IN PATIENTS WITH HYPERTENSION

Question: Do you believe that uterine bleeding may occur in patients with essential or benign hypertension?

Dr. Novak: I think it may, although it would be explainable on the basis of coincidence. I had not expected to say anything about hypertension. I think that perhaps Dr. Curtis ought to answer that question. I also have seen cases of otherwise unexplainable bleeding in which women happened to have hypertension. I have not felt sure that the hypertension had anything to do with it. The older men will remember discussions of uterine apoplexy. If a woman can have the hemorrhage in the brain, theoretically she could have a little hemorrhage from the uterine blood vessels, but, after all, I think that these cases are not frequent in which uterine bleeding is associated with hypertension, and we cannot be sure. I have seen several cases in my long experience, but I do not know exactly what the hypertension has to do with it.

CANCER AND HYPERTENSION

The Moderator: Dr. Novak, it has been suggested by Dr. Mengert that we have a discussion among the group. I cannot help feeling that we must admit that, other things being absent, a patient who has hypertension should not have quite as certain a precurettage diagnosis of cancer as one who has not hypertension.

Dr. Novak: Many of these patients with hypertension—the majority, I think—do have some other much more common and readily recognized cause, senile endometriosis, or something of that sort. If they take the cases numerically, that would be far more likely to be the cause of bleeding where there is no apparent cause. It is a difficult thing to prove, and I am sure that Dr. Curtis will agree, because of the fact that hypertension in the menopause is common. We cannot always make the proper diagnosis. Dr. Reynolds, do you want to say something about the possible role of hypertension?

Dr. S. R. M. Reynolds, Baltimore: Dr. Curtis asked whether hypertension might not be a factor in uterine bleeding. Of course it could be. If the pressure is transmitted to the capillaries, capillary lakes and venous lakes that may form within the subepithelial portions of the uterus, it might contribute to the bleeding.

The Moderator: It is transmitted through to the brain and causes apoplexy.

Dr. Reynolds: Yes, of course. These are localized episodes. While I do not want to discuss hemodynamics, I might mention the fact that among the factors that govern the pressure transmitted to a terminal artery is the diameter of the branch with relation to the diameter of the stem and the angle of arterial branching. If these relationships assume abnormal proportions, one may have excessive pressure and transmission of fluid to a localized area. I did mention in my paper that hemodynamic factors concerning which we have no objective facts contribute to the menstrual process. Dr. Doris Phelps last week reported at the Association for the Study of Internal Secretions experiments in which she set up in a group of monkeys standard conditions with respect to dosage of estrogen for the purpose of inducing bleeding by deprivation of estrogen. She found that she got better consistency in her results when correlating the bleeding characteristics in any given course of injections with the previous history of bleeding and the length of time that had lapsed between the two periods, rather than the particular course of injections preceding the period of bleeding. There was therefore some controlling factor carried over from one period to the next influencing the bleeding response to a course of injections of hormone.

ROLE OF LYMPHATICS IN MENSTRUATION

Question: Please repeat what you said with regard to the role of lymphatics in menstruation.

Dr. Reynolds: The physiologic factors and morphologic characteristics of the blood vessels which I have reviewed suggest that there is something missing in our present concept of a mere vasoconstriction of endometrial coiled arterioles in the control of menstruation. We have a menstrual toxin, so called, and we have menstruation occurring in species that do not have endometrial coiled arterioles. I merely raise the possibility that there is some other common denominator for the various kinds of menstrual bleeding. It seems to me, as a working hypothesis, that menstruation may well be associated in some way with a deficient mechanism for removing transuded plasma proteins in the endometrium because of a deficient lymphatic capillary circulation. Let those of us on the experimental side take a new tack, adopt a fresh approach and see whether or not we can get some other basis on which to explain the many conflicting facts concerning menstruation from "any type of endometrium." I raise the question of lymphatics in the endometrium as a working hypothesis, rather than as a statement of fact.

BLEEDING FROM ENDOMETRIUM

Question: Bleeding from hyperplastic endometrium has been discussed. Does not functional bleeding also occur from other types of endometrium, such as atrophic?

Dr. Novak: To generalize, bleeding can occur from any kind of endometrium.

The Moderator: I think this query is interlocked with the one you have now, Doctor if you will permit me to interrupt for a moment. There have been extrogenous pigmentation studies made on functional bleeding where the endometrium does not show the typical, nonsecretory Swiss cheese pattern.

Dr. Novak: As I started to say, bleeding can occur from any kind of endometrium. Hyperplasia of the endometrium never causes uterine bleeding in itself. Hyperplasia of the endometrium is simply an expression of the growth effect of the estrogen. We have to think of the endometrium, as having two types of cycle: one, a growth cycle, and the other, the bleeding cycle. The two do not necessarily go together in parallel fashion. In many cases the bleeding spill, whatever the cause may be, may occur at a low growth level in the endometrium. In other cases, hyperplasia may be present, and be present for weeks and weeks, and the woman has no bleeding. A woman with amenorrhea of long standing may have hyperplasia, because in her case the growth level is kept up by a steady, persistent supply and there is no drop in the level to precipitate the attacks. The bleeding of the functional type, therefore, is due to an interlocking, shuttlecock sort of relation between the pituitary and the ovary. The cases of hyperplasia one finds characteristically in an ovulatory functional bleeding but, as one of these questions brings out, functional bleeding may be also of the ovulatory type. In other words, we can get a secretory endometrium in a woman who has bleeding of the functional type. These cases are much less common, and we know much less about the mechanism. We know, in fact, almost nothing. Whether it is due to imbalance between the estrogen and the progesterone, or due to some disturbance of the vascular or muscular mechanism, we can only theorize. But the simplest division to make of our functional cases is the nonovulatory group and the ovulatory group. The ovulatory group is much more common, although the nonovulatory cycle is less common than the ovulatory throughout the reproductive period of life. It is relatively common at those very periods when functional bleeding occurs—puberty and the premenopausal years. It is an aberration of the anovulatory type that causes many cases of functional bleeding.

EFFECTS OF REMOVAL OF NORMAL UTERUS ON PERSONALITY

Question: Discuss the effects of promiscuous removal of comparatively normal uterus on the personality of these persons.

Dr J. P. Pratt, Detroit: As the menopause approaches, it is possible to be more lax in our indications for removal of the uterus, but that does not mean giving carte blanche to remove the uterus on sight. As Dr. Norman Miller recently reviewed the results of removal of the uteri in various hospitals in three different states, he found that something like 50 per cent were removed without demonstration of pathologic lesions after they were removed. That is to be decried; there should be a good reason for removing the uterus. This question implies a psychosomatic angle which is most important. If the uterus is to be removed at any time, it should be discussed thoroughly with the woman, and she should understand in advance what it means. She should not be scared by suddenly being told after operation that her uterus has been removed.

The Moderator: I am afraid I gave an erroneous impression of the therapy of radiation treatment for bleeding. We give a routine amount of radium for bleeding at or near the menopause. We resort to the massive dosage of radium only in those patients who have severe and persistent, intractable flushes; so it is a subsequent administration of radium in selected cases. It would be wrong to give a large dose of radium to every bleeding patient for whom one wished merely to stop menstruation. I wanted to call attention to the fact that if a woman after irradiation has marked flushes, one may be able to relieve those flushes through giving her more radium, such as one would give a patient with cancer.

MENOPAUSAL BLEEDING AND MALIGNANT GROWTHS

Question: What percentage of menopausal bleeding turns out to be malignant?

Dr. Pratt: That would be difficult to fix, because in some regions there is a great deal more therapeutic use of estrogen than in others, and induced functional bleeding is far more common in one community than in another. Even so, the relatively smaller percentage of menopausal bleeding (by "menopausal" I mean at the time of the menopause) would be due to malignant growths. After the menopause, there is a much higher percentage, as much as 50 to 60 per cent.

The Moderator: I am in accord with what Dr. Pratt has said, and I am sure that Dr. Novak is, that we must gage the amount of radium according to the patient.

LATE MENARCHE

Question: A single woman 18 years old has menstruated only once, the duration of which was ten days with no clots. This menstruation was five months ago. Her mother did not menstruate until her eighteenth year and has 4 living children. Please discuss this.

Dr. Reynolds: From the physiologic standpoint there is not much to say. This is probably a case of late menarche. It is entirely possible to have cyclic ovarian activity and not necessarily have menstruation occur. I recall the experiments of Dr. Markee, who observed the endometrial transplant in the eye of a monkey and found that there was a definite relationship between the growth cycle of the endometrium and bleeding in the transplant. Bleeding occurred only when regression or thinning of the endometrium was sufficiently rapid and adequate in amount. So one has to suppose that the menstrual mechanism, as part of the endocrine cycle, is dependent on the rate of withdrawal and so on the rate of thinning as well as the absolute amount of regression of the endometrium. In such a case as this, I think it is entirely possible, though we cannot be certain, that the ovarian hormone withdrawal phase in these persons is much less abrupt, and so the regression is less abrupt. Consequently bleeding does not take place.

CERVICAL METAPLASIA AND CARCINOMA

Question: Does cervical metaplasia produce the same individual cellular morphologic change that carcinoma in situ does?

Dr. Novak: I will say no.

USE OF RADIUM

Question: What is the real objection to using radium in a young woman that curettage has failed to relieve, say 400 to 600 mg.?

The Moderator: Thirty-five years ago I did a long piece of work on the pathology of the cervix. Incidentally, I mentioned the use of radium in checking discharges. Nobody paid any attention to the vital work on pathology, but they all took up with the use of small doses of radium intracervically. In doing intracervical work with a small dose of radium, such as 350, 400 or 600 millicuries, I had opportunity to note the effects on the other pelvic viscera. The use of a small dose of radium is a good deal like putting a too hot sun on Iowa corn: you get radium-sick ovaries. I beg you not to do it.

MENSTRUATION THROUGHOUT PREGNANCY

Question: Some women claim to menstruate regularly throughout a normal pregnancy. What is the nature of such bleeding?

Dr. Novak: Bleeding of that type is usually due to an adventitious factor and is not genuine menstruation. It is often due to such conditions as an eroded cervix, or a cervical polyp which bleeds at irregular intervals. In other words, the bleeding is not as periodic as perhaps the woman herself assumes. Bleeding of an apparently normal menstrual type for one period is relatively common, but it is not genuine menstruation. It is the so-called implantation bleeding which occurs when the egg burrows into the endometrium, which erodes the blood vessels which fill up the little spaces. The blood often breaks through into the uterine glands and makes its way to the surface and externally. Bleeding of this sort is usually less abundant than it is with the normal menstruation. The women who menstruate one month, for example, after they are pregnant, will generally tell you that it is not as free as usual. Even if the bleeding is not present in macroscopic form, it is often present in microscopic form. It would probably be found to be present in a large proportion of cases. One such study has been made and bears out that impression. Whether genuine menstruation can occur is not quite so certain, but it probably can. It can on the basis of a few isolated observations. One German investigator many years ago had an opportunity to operate on pregnant woman, and by the demonstration of corpora lutei of different ages, he concluded that the periodic bleeding was of a genuine menstrual character.

VICARIOUS MENSTRUATION

The Moderator: Do you believe in vicarious menstruation?

Dr. Novak: Yes, I have seen instances—I am sure most of you have—of vicarious menstruation from the nose or from the lungs. We have not sufficient time to discuss it in detail, but I can illustrate. I had a pseudoform hermaphrodite who bled from her nose at about monthly periods, bleeding from various other cavities, and she also had large subcutaneous ecchymoses on her leg, which I could see. She did not have any vagina. She did not bleed externally. The question of the mechanism of these cases is interesting, and the question of distinction of types is interesting. Even if a woman has tuberculosis and has hemoptysis, if it comes only at the time of menstruation I think that it is vicarious menstruation. In case of such lesions in the nose, we have known for many years that there are two little areas in the nose—so-called genital tubercles—which respond to estrogen. It is not necessary to assume the presence of endometrial tissues, because on the basis of animal experimentation such as that done by such excellent investigators as Sutterman, it has been found that estrogen produces a tremendous engorgement of these so-called genital areas. At the time of menstruation it has been shown that there is an increased fragility of the blood vessels throughout the body. There was a study made some years ago on this subject. And so there is every reason to feel that the phenomenon of vicarious menstruation is a genuine one, although of course many menstruations which are not genuinely vicarious in character, in the sense of occurring at regular intervals, are sometimes loosely included under that designation.

The Moderator: In confirmation of what Dr. Novak said, there is no question in my mind, from personal experience and the experience of others, that the taking of large doses of estrogens tends to increase the genital areas of the nose and thus helps to make blockage of the nasal spaces. We must beware of estrogenic medication in large amounts over a long period of time in persons with high blood pressure.

"DYSFUNCTIONAL BLEEDING"

Question: From the standpoint of correct terminology, should not the term "dysfunctional bleeding" be used for "abnormal uterine bleeding?"

The Moderator: "Functional bleeding" is the accepted term and, to me, is less confusing than "dysfunctional bleeding."

VAGINAL OR ABDOMINAL HYSTERECTOMY

Question: Which method of hysterectomy—vaginal or abdominal?

Dr. Pratt: I think that depends primarily on the operator's ability to do one better than the other. There are also definite indications for choice, such as relaxation of the vagina, making the vaginal approach easy or difficult.

TESTOSTERONE FOR FUNCTIONAL MENORRHAGIA

Question: Do you give testosterone for ten days preceding the period in cases of functional menorrhagia?

The Moderator: I give methyl testosterone, three tablets daily, with great bleeding, and only during the bleeding. I give two tablets daily when there is moderate bleeding and none when there is slight bleeding.

EFFECT OF ESTROGEN THERAPY

Question: What is the effect of estrogen therapy on the ovaries of young girls?

Dr. Novak: Moderate doses could cause no effect. If the dosage is excessive, ovarian function is inhibited. It is possible to convert the ovaries of an animal or a woman into functionless organs by sufficiently large doses of estrogen, but the ovary always has a tendency to bounce back, and sooner or later it will reestablish its function.

EFFECT OF ROENTGEN RAYS ON OVUM

Question: Do you believe that the mutations in the fruit fly should influence the use of the only mechanism, roentgen rays, which actually induces ovulation?

Dr. Novak: The question obviously has bearing on the controversial question as to the employment of roentgen rays in various menstrual disorders. This obviously refers particularly to the opposite condition of what we are discussing, amenorrhea and sterility. The chief work along the line of genetics has been done in animals like mice and rats. I do not know whether any of you were present at a discussion of this subject which was held at a previous Atlantic City session of this Section, and the question of roentgen treatment was under consideration. Many of us are rather concerned about it. Others, as you know, are very enthusiastic. It is true that the men who use x-ray stimulation can apparently report fairly good results, probably better than many of us can report from hormone and other therapy, and yet I think that the conservative gynecologist is a little hesitant—I know that I am—about the use of roentgen rays. We feel this conservatism chiefly on the basis of what the geneticists tell us. Dr. Little said he had not for obvious reasons been able to make experiments, but that he knew in the case of lower animals, mice or rats, that roentgen therapy of this sort would have a serious effect not on the immediate offspring but on the offspring of subsequent generations. I do not know whether that is applicable to the human being or not. I think that Dr. Little himself did not pretend to know, but such considerations must make us hesitate somewhat.

STAIN USED FOR VAGINAL SMEAR

Question: What stain is used for vaginal or cervical smear?

The Moderator: Dr. Papanicolaou changes his stain a little, rather frequently. I say that without criticism. He is a wonderful man.

DEFICIENCY IN COAGULATING CONSTITUENTS OF BLOOD

Question: Does a deficiency in the coagulating constituents of the blood cause abnormal uterine bleeding?

The Moderator: All systemic derangements are factors in causing bleeding. We have purposely ruled out all those which the internists should attend to.

ENDOMETRIOSIS AND ENDOMYOSIS

Question: Kindly differentiate between endometriosis and endomyosis, and their role in functional bleeding.

Dr. Novak: "Endomyosis" is a term with which I am not familiar. Endometriosis has no characteristic role. We will assume that the questioner means adenomyosis." Neither has an important effect in bleeding. Of course, either one can be associated with bleeding, but the bleeding in the large proportion of cases is due to an associated dysfunctional factor. Bleeding, in many cases, of the endometriosis is due to associated bleeding of the functional type. The same with endomyosis—not entirely, because we have other possible factors.

TESTOSTERONE AND ESTROGENS

Queston: Is testosterone going to supplant estrogens in menopause symptoms in the future?

The Moderator: We do not know. The problem is in a state of flux, still confused.

SENILE VAGINITIS

Question: What would your treatment be for senile vaginitis?

Dr. Pratt: I would treat local infections with mild antiseptics, and in the early stages, estrogenic therapy. After adhesions are formed, there is no treatment.

"LIQUID" VERSUS "SOLID" PENICILLIN IN OIL AND WAX

The Effect of Particle Size and Type of Penicillin

HARRY F. DOWLING, M.D.
MONROE J. ROMANSKY, M.D.
HENRY WELCH, Ph.D.
JAY A. ROBINSON, M.D.
VELMA L. CHANDLER, M.S.
WILLIAM W. ZELLER, M.D.
and
HAROLD L. HIRSH, M.D.
Washington, D.C.

The incorporation of penicillin in oil and beeswax has been found to be a satisfactory method of prolonging the absorption of penicillin. Romansky and Rittman,[1] the originators of the method, showed that after the injection of 300,000 units of amorphous calcium penicillin in oil and wax 70 per cent of the patients so treated had demonstrable blood concentrations of penicillin for twenty-four hours. Several modifications of the original preparation have now been made and utilized clinically.[2] Crystalline sodium and potassium as well as the amorphous calcium penicillin were found suitable for use in the mixture. Furthermore, certain preparations were devised which were fluid at room temperature and did not require heating before injection.

The liquid preparations of penicillin in oil and wax, which are fluid at room temperature (below 43.3 C. or 110 F.),[3] are now available commercially and are identical in composition with the original viscid (so called "solid") type. These preparations have been prepared by a change in their physical state only. Fluid preparations of penicillin in oil and wax are to be preferred over the more viscid ones because they are easier to administer. The viscid ("solid") preparations require heating before injection, are difficult to extract from the vials and, if administered in 1 cc. disposable syringes, are very expensive.

Because of its purity, crystalline penicillin is less likely to cause reactions than amorphous penicillin. In addition, it is more stable and can be kept at room temperature for longer periods of time than the amorphous preparations. Obviously the liquid preparations, utilizing crystalline penicillin, are preferable, if it can be demonstrated that they will produce as much prolongation of the blood penicillin concentrations as the amorphous and viscid preparations. Data furnished to the Food and Drug Administration by various manufacturers seemed to indicate that preparations of crystalline penicillin were superior to preparations of amorphous penicillin. On the other hand, there was considerable variation in the results obtained with products made by these manufacturers and, in fact, within the batches obtained from a single manufacturer. Only two reports [4] have been published concerning the ability of the liquid preparations to prolong the blood penicillin concentrations. These authors stated that when 300,000 or 600,000 units of penicillin in this form was injected intramuscularly, prolongation of its effect was not as great as had been obtained with some viscid preparations.

Because of the importance of determining which of the available preparations is the more suitable and because more data were needed to clarify these points, the present study was undertaken. A total of 252 patients in the wards of Gallinger Municipal Hospital were treated with various preparations of penicillin produced by eleven manufacturers. These preparations consisted of crystalline penicillin (sodium and potassium) and amorphous calcium penicillin in oil and wax, both in the "solid" and "liquid" forms. Each subject was given 300,000 units of penicillin in 4.8 per cent beeswax in oil contained in 1 cc. by a single intramuscular injection. Blood was collected at the twelfth, sixteenth, twentieth and twenty-fourth hour after injection. Each specimen was identified by a code number, and one half was submitted to the Antibiotic Section Laboratory, Walter Reed General Hospital, for penicillin assay by a modified Rammelkamp method.[5] The other half was sent to the Division of Penicillin Control and Immunology of the Food and Drug Administration for assay by the "subtilis" technic.[6] In the "subtilis" technic, a control was performed with each blood specimen to eliminate false readings due to the presence of an antisubtilis factor in human blood.[7]

Early in the investigation it became apparent that the size of the particles of penicillin used in preparing the liquid forms influenced considerably the prolongation of the blood penicillin concentrations. Accordingly, a method was devised for determining the relative weight of the penicillin particles. The details will be published elsewhere.[8] Preparations found by this method to contain 50 per cent or more of the total relative weight of particles measuring greater than 50 microns were classified as "large particle" preparations. Those with less than 50 per cent of the particle by relative weight in this range were classified as "small particle" preparations.

The percentage of patients showing measurable blood concentrations obtained at various intervals after injection of 300,000 units of penicillin in oil and wax in a single dose using "solid" and "liquid" preparations prepared with large or small particle amorphous or crystalline penicillin are given in the table. The percentage of subjects that showed measurable blood levels by both the Rammelkamp and "subtilis" methods are tabulated for all types of penicillin in oil and wax used. In nearly every instance penicillin was detected in a greater percentage of blood specimens by the "subtilis" technic than by the Rammelkamp method. It should be noted that the "subtilis" method is slightly more sensi-

L.: A Method for Determining the Size and Relative Weight of Penicillin Particles and Its Importance in Preparing Adequate Preparations of Liquid Penicillin in Oil and Wax, to [illegible] ished.

tive than the Rammelkamp technic, since the Bacillus subtilis can measure a minimum of 0.03 unit of penicillin per cubic centimeter of serum, while the streptococcus used in the Rammelkamp method can measure approximately 0.039 to 0.078 unit per cubic centimeter of serum.

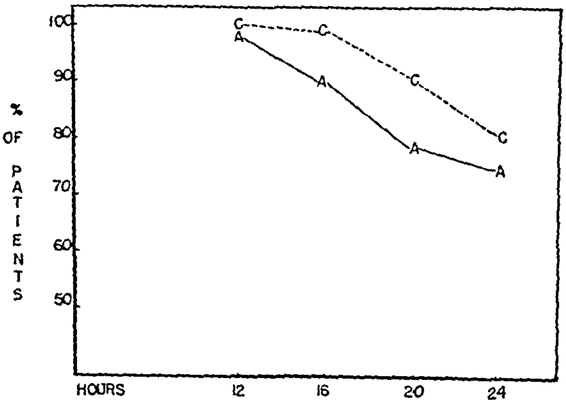

Chart 1.—Comparison of the percentage of patients with measurable blood concentration of penicillin following a singular muscular injection of 300,000 units of crystalline and amorphous penicillin in oil and wax ("subtilis" technic).

It will be seen from this table and chart 1 that when particle size and viscosity are not considered, the crystalline preparations are in general superior to the amorphous, when comparison is made on the basis of the number of subjects showing demonstrable concentrations of penicillin in the blood at various intervals after the original injection. Furthermore, each type of the crystalline mixtures was superior to the comparable type of amorphous.

From the table and chart 2 it is evident that the large particle preparations were apparently superior to those containing small particles when "solid" preparations were used, and definitely superior to small particle preparations when the "liquid" form was used. The best liquid preparation, that which contains crystalline penicillin in large particles, is as good as the best solid preparations, namely, those which contain crystalline penicillin, whether in large or small particles.

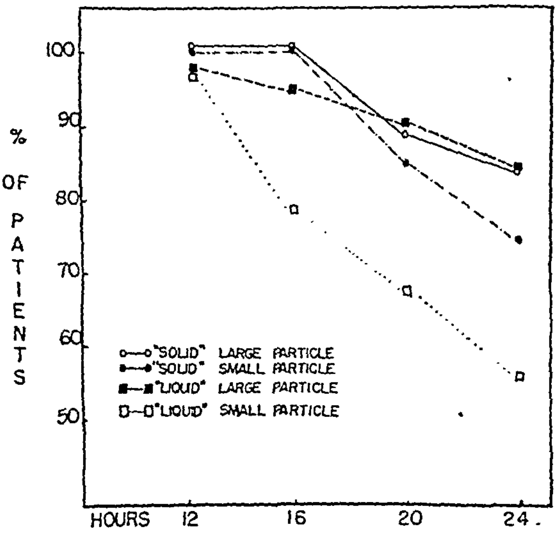

Chart 2.—Percentage of patients with measurable concentration of penicillin in the blood following the injection of 300,000 units of various types of penicillin in oil and wax.

COMMENT

The goal which the physician desires to achieve by the use of repository injections of penicillin is the maintenance of a therapeutic concentration of the antibiotic in the blood for the longest possible time. Since many preparations of penicillin in oil and wax lengthen the period during which therapeutic concentrations are present in the blood, it is desirable to determine which ones will do this best. Our investigations demonstrate that preparations made with crystalline penicillin are superior to those made with the amorphous material, provided that the particle size and the viscosity of these preparations are comparable. Furthermore, liquid preparations are as good as the viscid ("solid") preparations if 50 per cent or more of the total relative weight of the particles consists of measurable particles greater than 50 microns. Liquid preparations containing penicillin of smaller average particle size than this, whether amorphous or crystalline, are definitely inferior to the solid preparations. Since the liquid preparations are easier to administer, it is obvious that they will be the preparations of choice.

Percentage of Patients with Measurable Blood Concentrations Following a Single Intramuscular Injection of 300,000 Units of Penicillin in Oil and Wax

		Blood Levels of Penicillin							
		12 Hours		16 Hours		20 Hours		24 Hours	
Type of Penicillin in Oil and Wax	No. of Patients	Subtilis	Rammelkamp	Subtilis	Rammelkamp	Subtilis	Rammelkamp	Subtilis	Rammelkamp
"Solid"									
Large particle:									
Amorphous........	20	100	90	100	73	90	65	80	47
Crystalline........	20	100	90	100	88	88	84	90	70
Small particle:									
Amorphous........	48*	100	98	100	90	83	63	71	50
Crystalline........	19	100	100	100	94	94	90	90	66
"Liquid"									
Large particle:									
Amorphous........	34	97	86	94	67	85	54	82	34
Crystalline........	37†	100	97	100	97	100	97	92	89
Small particle:									
Amorphous........	50*	96	71	75	56	65	30	41	14
Crystalline........	24	100	96	91	82	83	81	56	43

* Of the 48 and 50 patients in these two groups, the bloods of 6 and 5 patients, respectively, were not assayed by the Rammelkamp technic.

† Of the 37 patients in this group, the bloods of only 11 were assayed by the "subtilis" method.

It should be emphasized, however, that the precautions observed for the "solid" preparations, namely, those concerning the use of dry needles and syringes and deep intramuscular injections, should be followed when the fluid preparations are employed. In addition, the fluid preparations must be shaken vigorously before use.

Preparations containing crystalline penicillin, which is more highly purified, can be stored at room temperature for eighteen months as compared with only twelve months for the amorphous material. In addition, they give therapeutically significant blood concentrations for longer periods than the preparations containing amorphous penicillin. For these reasons crystalline will be preferred to amorphous preparations.

SUMMARY AND CONCLUSIONS

Various preparations of penicillin in oil and wax, crystalline and amorphous, "solid" (viscous) and "liquid," those with large particles and those with smaller particles of penicillin, have been studied by giving a single intramuscular injection containing

300,000 units to patients and then determining the concentrations of penicillin in the blood at twelve, sixteen, twenty and twenty-four hours after the injection.

Preparations of crystalline penicillin in oil and wax were superior to preparations which were comparable in other respects but which contained amorphous penicillin. Solid preparations gave optimal results, if crystalline penicillin was used, whether the particles were of large or small size; or, if amorphous penicillin was used, when the particles were of large size. Liquid preparations gave optimal results if crystalline penicillin of large particle size was used and almost as good results with amorphous penicillin of large particle size. Liquid preparations containing penicillin of small particle size, whether amorphous or crystalline, gave definitely inferior results.

On the basis of ease of administration as well as on the concentrations of penicillin achieved in the blood, the liquid preparations of crystalline penicillin of large particle size are recommended as the most satisfactory form of penicillin in oil and wax.

MULTIPLE SCLEROSIS

Diagnosis and Treatment

NATIONAL MULTIPLE SCLEROSIS SOCIETY
New York

MINIMUM STANDARDS OF DIAGNOSIS

The essential criteria of diagnosis of multiple sclerosis are evidences of lesions affecting white matter chiefly, scattered in time and space (that is, repetitive attacks which often give the disease a recurrent regressive and progressive character). Ordinarily, the diagnosis cannot be made unless there is evidence of more than one lesion or unless there are confirmatory findings in the spinal fluid, but characteristic symptoms such as retrobulbar neuritis with central scotoma, symptoms of acute transverse myelitis, diplopia or blurred vision or weakness or numbness of one extremity, if transient, create a presumption for the diagnosis. This presumption is strengthened if one or more of the common physical findings is present, such as palsy of one of the oculomotor nerves, nystagmus, slight ataxia of the arms, absent abdominal reflexes or Babinski or Oppenheim signs.

In addition to the foregoing manifestations the following are frequently found: difficulty in speech, monoparesis or hemiparesis, spastic paraplegia, spastic-ataxic gait, vertigo, intention tremor, frequency and urgency of urination, impotence, constipation, girdle sensations and other paresthesias, loss of vibration and position sense and general weakness.

Some type of alteration in the spinal fluid is found in about 70 per cent of cases. These include a moderate increase of cells (10 to 100), increase of total protein and alterations in the gold-sol curve (which should always be performed in suspected cases).

Uncommon manifestations are papilledema, psychoses, trigeminal and other types of neuralgia, facial palsy, headache, aphasia, hemianopia and convulsions.

Multiple sclerosis usually begins between the ages of 20 and 40 but is not excluded by an onset before or after these limits. The symptoms are often precipitated by infection, by emotional tension or pronounced fatigue and sometimes by pregnancy, and if so, the diagnosis is rendered more probable.

A steadily progressing disability or one limited to the lower extremities calls for caution in diagnosis. In doubtful cases neurosyphilis, neoplasm, subacute combined sclerosis and hereditary ataxia must be considered.

When the sensory symptoms are decidedly pronounced, hysteria is occasionally mistakenly diagnosed.

The accompanying table, modified from Sachs and Friedman, is often of value:

Symptoms and Signs Enumerated in the Order of the Frequency of Their Occurrence

Total number of cases studied 141 (male cases 77, female 64)

		Cases	Per Cent
1	Abdominal wall reflexes decidedly diminished or absent	118	83.7
2	Chief complaint weakness and stiffness of one or both lower extremities	115	81.7
3	Nystagmus (chiefly horizontal)	99	70.0
	Horizontal and vertical	17	12.0
	Horizontal and rotary	3	2.0
4	Babinski's sign present bilaterally	94	67.0
	Unilaterally	16	11.3
5	Tremor present in extremities alone	78	55.3
	Tremor of the head also	31	22.0
6	Ataxia and adiadokokinesis	66	47.0
7	Deep reflexes in the lower extremities increased	126	90.0
	Ankle clonus	61	43.0
	Patellar clonus	29	20.5
	In 3 instances the knee jerks were diminished (tabetic type)		
8	History of one or more remissions	59	42.0
9	*Bladder symptoms*	57	40.0
	Urgency	18	12.6
	Delay in starting urinary stream alone or in combination with urgency in 23 cases and incontinence in 21 cases		
10	Speech hesitant or otherwise disturbed	51	36.0
11	Gait spastic	43	30.0
	Spastic ataxic	46	32.6
	Ataxic alone	15	10.6
12	Evidence of facial weakness (other cranial nerves very much less involved)	46	32.6
	Tongue deviated to the right	14	10.0
	Difficulty in swallowing	5	3.5
	Uvula drawn to one side	4	2.8
	Cochlear nerve involved	3	2.0
	Vestibular nerve showed no response to stimulation	2	1.4
	Ocular muscles:		
	Internal rectus involved	6	4.3
	Ptosis	2	1.4
	External rectus involved	3	2.8
13	Temporal atrophy	46	32.6
	Blurring of the disks or mild optic neuritis	11	7.8
	Vision impaired without objective disk findings	25	17.7
14	Pain, numbness and tingling	43	30.0
	Objective disturbances in posterior column sensation	24	17.0
	Mild changes in pain, temperature and touch perception (including cases with hyperalgesic zones)	23	16.3
	Astereognosis	5	3.5
15	*History of diplopia*	31	29.0
16	Cremasteric reflexes diminished (males)	17	22.0
17	Mental changes (largely those of mental infantilism and signs of neurosis or neurasthenia; 1 patient was in a state hospital with the diagnosis of dementia precox; 1 patient showed the picture of Korsakoff's psychosis)	22	15.8
18	Emotional instability with explosive laughter	24	17.0
	Defects of memory	7	5.0
19	Spinal tenderness (chiefly middorsal)	17	12.0
20	History of trauma	14	10.0
21	Pupillary disturbances rare:		
	Pupils irregular	6	4.3
	Slightly sluggish to light	12	8.5
	Anisocoria	16	11.3
22	History of pronounced dizziness	12	8.5
23	Disturbances of potency	6	4.3
	(No disturbances in rectal control in any cases)		

TREATMENT

There is no agreement among neurologists in regard to the cause of multiple sclerosis; hence, no specific treatment directed at its cause is generally accepted. Many purely empiric treatments have been described. Since none of them have been shown by adequate statistical method to influence the course of the disease, they

---

Prepared by qualified member neurologists and approved by the Medical Advisory Board of the National Multiple Sclerosis Society, an association for advancement of research on multiple sclerosis, Academy of Medicine Building, Fifth Avenue and 103d Street.

will not be detailed here. An account of them may be found in Brickner's article (*Bull. Neurol. Inst.*, New York. 4: 655, 1936), and an analysis of the results in an article by Putnam (THE JOURNAL, June 17, 1939, p. 2488).

There are certain natural limitations to all forms of treatment in multiple sclerosis. Recent pathologic studies have made it clear that a large proportion of axis-cylinders are often destroyed in the acute phase of the disease process; as the acute phase passes by, a certain tendency to recovery can usually be observed. The larger the lesion and the longer the disease has continued, the more severe the damage to axons. Any useful regeneration of axis-cylinders in the central nervous system is at present inconceivable. Possibly the formation or growth of lesions might be prevented by avoiding precipitating factors or counteracting the disease process; possibly mildly damaged nerve elements might be restored by some alteration in nutrition or circulation, and certainly some long-standing symptoms may be alleviated, for example, by relaxation exercises and retraining, which obviously have no beneficial effect on the disease itself. Whatever course of treatment is chosen in a given case, the physician should always bear in mind its rationale and should not expect more of it than it can conceivably accomplish.

I. MORALE BUILDING

Inasmuch as there is no satisfactory specific treatment for multiple sclerosis the physician must approach the problem somewhat obliquely. These patients are in a situation which they consider threatening and have a strong need for someone on whom they can be dependent. This constitutes a large part of the treatment responsibility. The physician can best serve the patient as a wise counselor who helps to relieve anxiety, to work out ways of overcoming physical handicaps and to develop positive interests which make the situation more tolerable. Since new symptoms often appear in a setting of anxiety and tension, a relief of these anxieties may help to prevent further progress of this disease. This approach to the problem may be called morale building.

Morale building should be constantly in the mind of the physician, because the most insignificant attitude displayed to the patient may be of profound importance in either a positive or a negative direction. The physician should first define his own attitude toward the disease. If possible he should assume a mature perspective which is realistic but takes into account plastic features as well as those which are unmodifiable. The physician who has responsibility for therapy is confronted by a double problem of treating the disease itself and treating the patient, or, more precisely, treating the problem which the disease represents to the patient. The problem is to aid the patient to deal with the disease in an effective manner. The most helpful attitude is to consider that this disease, as any serious life problem, presents a challenge which the patient needs to meet effectively. Though the disease is a serious liability, which need not and cannot be minimized, there is available to the patient the satisfaction of coping with and "overcoming" the liability.

Before informing a patient concerning specific features of the disease and factors which are likely to bring on new symptoms, it is wise to estimate the patient's capacity for dealing effectively with anxiety. Otherwise new fears may be introduced which will only aggravate the situation. After a good patient-physician relationship has been established palliative drugs may have beneficial value out of all proportion to the value of the drug itself. This good relationship is easy to establish, for the patient is seeking frantically for some understanding person who is willing to listen to his problem. The function of the physician is to listen in an understanding way and to give a minimum of directive advice. The physician should rather assist the patient to arrive at his own conclusions. By sympathetic listening the physician helps the patient bring into sharper focus his own plans for dealing with the illness in a constructive way.

The forms of treatment at present in use may be divided into: (1) those aimed at recognized precipitating factors (including climatic treatment); (2) those founded on current theories of the etiologic basis of the disease, and (3) those aimed at alleviating individual symptoms.

II. AVOIDANCE OF PRECIPITATING FACTORS

The usual list of circumstances which may precipitate attacks is as follows: infections, unfavorable climate, pregnancy, fatigue, poor nutrition, emotional disturbances and chilling.

Infections.—The effect of acute infections, such as the common respiratory infections, boils and paronychias, is often striking. In every case a search for foci of infection, such as sinusitis, tonsillitis, infected teeth and prostatitis, should be instituted and the focus dealt with if possible. Avoidance of infections is desirable but difficult to attain. Probably the influence of climate lies chiefly in its influence on incidence of infections.

Climate.—Multiple sclerosis appears to be a disease of cold, damp climates. It is commonest in northern Great Britain, the Baltic countries and certain areas of the United States (the northern Atlantic coast, the Great Lakes states and the northern plains). It is apparently relatively infrequent in the Mediterranean countries and in the Southern and Southwestern states. It seems to be almost unknown in China and Japan. Patients afflicted with multiple sclerosis often complain that in cold or damp weather their symptoms are more pronounced. Patients who move from an unfavorable climate to a mild, dry one such as exists in the Southwestern area of the United States (Arizona, Northern Texas, New Mexico, Colorado, Southern California) are often relatively free from acute relapses and may go into a remission. Further statistical studies on this point are being made by the Society.

Pregnancy.—The onset of multiple sclerosis, or relapses, are precipitated in about 40 per cent of female patients who become pregnant. Measures to be taken are obvious.

Fatigue, Poor Nutrition, Emotional Disturbances, Chilling.—Relapses sometimes seem to be precipitated in persons suffering from multiple sclerosis by periods of overwork, long automobile rides and exposure to cold. Severe reducing diets, carbohydrate "sprees" and other dietary vagaries sometimes seem to have a disadvantageous effect. There is, however, no good evidence that any specific dietary factor—e. g., presence of vitamins—has a bearing on the disease. Indeed, it is rarest in some regions in which vitamin deficiencies are most frequently observed, but care should be taken that the patient has a better than average diet and the best possible living conditions. Emotional disturbances and emotional tension in particular are apt to precipitate attacks. Whatever can be done should be done to maintain as calm an emotional level as possible.

Injury.—The role of injury in the causation of multiple sclerosis is hard to assess, and avoidance of injury is difficult to attain. It should be considered, however, in planning the lives of patients. Sometimes even such trifling trauma as lumbar puncture or venipuncture may appear to precipitate attacks.

III. REHABILITATION AND SYMPTOMATIC TREATMENT

Physical Therapy.—Excellent results have apparently been obtained in a number of cases of chronic multiple sclerosis by muscular reeducation. However, rehabilitation in chronic multiple sclerosis is difficult and may be impossible in the severely involved patient who has been confined to bed or a wheelchair for a number of years. The approach to therapy has been to attempt to restore function by development of substitute motor pathways in the central nervous system. Treatment at one institute devoted to physical therapy consists of daily administration of neostigmine in large dosage and daily intensive muscle reeducation with specialized carefully prescribed resistance exercises.

The following recommendations are made as the result of the experience obtained in the Department of Rehabilitation and Physical Medicine, Bellevue Hospital, New York:

> The methods which have been found useful in disabilities which limit motions at the joints, weakness, spasticity, rigidity and incoordination of muscles are the physical modalities heat, water, massage and therapeutic exercise. Therefore the use of physical and occupational therapy and rehabilitation procedures is useful in the symptomatic treatment of multiple sclerosis.
>
> Before planning a program for patients with multiple sclerosis it is essential that a physical therapeutist evaluate joint motion and muscle strength and function.
>
> 1. *Joint Motion.*—Every joint has a specific number of movements and range of motion. The therapeutist should test each joint to discover if there are any limitations of motion and the extent of the limitation.
>
> 2. *Muscle Test.*—The therapeutist should also give a muscle test, as is done in poliomyelitis, in order to discover the muscle groups which are paralyzed, weak, spastic or rigid. Muscle tests repeated over a period of months will give valuable information on the progress of the disease or results of the treatment.
>
> 3. *Functional Activities Test.*—The functional activities test consists of activities essential for daily living. A detailed classification of activities essential for daily living which is in use in the Department of Rehabilitation and Physical Medicine, Bellevue Hospital, can be obtained from that hospital on request. This test evaluates what the patient can do with his disability in performing activities which require movements at the joints, muscle power and coordination. When the physician has these evaluations he is prepared to plan a program best adapted to meet the physical needs of the patient.
>
> *Treatment of Disabilities.*—The following physical modalities are used in treating the disabilities resulting from multiple sclerosis:
>
> 1. Massage: The movements employed in massage are useful in accelerating the flow of blood in the skin; subcutaneous tissue and muscles. Massage is also useful in producing a sedative effect on the nervous system, thus relieving spasm and rigidity of the muscles.
>
> 2. Hydrotherapy: Warm baths tend to produce relaxation of the muscles and relieve pain.
>
> 3. Exercise: There is no form of physical therapy as useful in the treatment of patients with multiple sclerosis as active and passive movements. By means of such exercises the movements of the joints as well as the strength of muscles and coordination may be maintained and increased.
>
> (*a*) Passive movements are useful in overcoming spasticity and contractures of the muscles, adhesions in the joints and tightening of the ligaments. They prevent deformities which may interfere with use of the extremities should remissions occur.
>
> (*b*) Active movements and the arts and crafts activities are used by the therapeutist to strengthen the muscle groups which are below normal to prevent atrophy from disuse and to maintain or reestablish coordination.

OTHER FORMS OF SYMPTOMATIC TREATMENT

Curare.—The usefulness of curare in multiple sclerosis is limited to those cases exhibiting spasticity. Where indicated, its therapeutic value may be twofold. First, the reduction in hyperactive stretch reflex (characteristic of spasticity) may unmask the patient's remaining motor power by increasing the efficiency of motor management. Second, the lessening of spasticity may permit increased range of motion and, coupled with competent physiotherapy, prevent contractures incident to prolonged abnormal postures.

In cases in which spasticity is associated with good voluntary power, curare therapy along with adequate reeducation may yield striking rehabilitative results. On the other hand, in cases in which voluntary strength is at a minimum the limbs will adopt a position dependent on the strongest muscle groups in spite of reduction in hyperirritability of the stretch reflex. In such instances, administration of a preparation of curare along with frequent passive motion may be of value in preventing or overcoming contractures. In some patients the use of curare appears to increase fatigue.

Two types of drugs are in use: aqueous tubocurarine, which is a crystalline derivative of crude curare, and a suspension of d-tubocurarine chloride in oil and wax. The former has the disadvantage of evanescent effect and possibly a narrower therapeutic margin; use of the latter, while showing more promise in the treatment of chronic states, is still frankly experimental. The rationale in the use of this drug is based on its ability to create a partial neuromuscular block. This may be a different physiologic mechanism from the purely paralytic effect achieved with larger doses.

Curare is known to have histaminic side effects. These occur in about 10 per cent of the cases and are ordinarily not troublesome and do not require special care. However, subjective vertigo is sometimes seen, and this in the presence of ataxia may eliminate the drug as a therapeutic choice in a given case. No tolerance has been seen to develop, and over long periods of time there has been no demonstrable effect on bodily economy. Curare is, of course, a potentially dangerous drug, and several deaths have been attributed to its use. It should be prescribed only by physicians who have had experience with its actions, and a supply of neostigmine, its physiologic antidote, should be kept available.

Neostigmine.—Neostigmine has been used much in the manner recommended in the preceding section for curare. This is curious, because the two drugs have pharmacologically opposed actions. Neostigmine was originally prepared as an antidote to curare.

Miscellaneous Agents.—Various drugs, such as amphetamine, dextro-amphetamine ("dexedrine"), diphenhydramine ("benadryl") and tripelennamine ("pyribenzamine") have been used in the treatment of chronic cases and have occasionally appeared to give symptomatic relief.

Antireticulocytotoxic serum (A.C.S.) is under trial, and results will be reported when the tests are completed.

Vitamins have been extensively used. In some cases they seem to have a tonic effect, and their use is definitely indicated if any signs of actual deficiency, such as redness of the tongue, rhagades, anemia and dryness of the skin and hair, appear. They do not appear to have any specific effect on the course of the disease in well nourished patients.

Treatment of Other Symptoms.—Constipation: Constipation is a common concomitant of multiple sclerosis. It may be treated by laxatives; diets; the use of agar-oil mixtures or mucilaginous laxatives, or by such mixtures as figs, senna and prunes. Salts and drastic cathartics should be avoided if possible. Enemas are often necessary.

Urinary Retention and Incontinence: Frequency and urgency of urination may often be helped by moderate doses of tincture of hyocyamus or other antispasmodics, such as "trasentin" (the hydrochloride of diphenylacetyldiethylaminoethanol).

Urinary infection should be vigorously combated, as it tends to cause progression of the disease. Use of forced fluids and antiseptics, such as sulfadiazine by mouth, may be all that is necessary. The use of tidal drainage should be employed if the infection is rebellious or if the bladder is fibrotic and contracted.

In prescribing the indicated forms of therapy the physician must be guided by the knowledge of the disease which the patient has, as well as by his own knowledge of the patient who has the disease.

IV. TREATMENTS FOUNDED ON CURRENT THEORIES OF THE DISEASE

1. *Treatments Aimed at Possible Specific Infections.*—The idea that multiple sclerosis is the result of a specific infection, for example, by a spirochete or virus, is now an old one, which is revived from time to time. The disease has therefore been treated by many antibiotic substances, such as arsphenamine and its modifications, "germanin" (suramin sodium U. S. P.), silver salts, iodides and penicillin, but without obvious results. Fever treatment has also been generally abandoned, as has the use of various vaccines.

2. *Treatments Based on the Theory of Vascular Spasm or Thrombosis.*—A. "Dicumarol": Based on accumulating evidence which suggests the possibility that vascular obstruction, probably a thrombosis of venules, is a link in the chain of causation of multiple sclerosis, "dicumarol," an anticoagulant, has been used in certain cases. Most of the chronic progressive cases treated with this drug continued their downward course.

1. In view of the special and important technical knowledge and skill required in the use of "dicumarol," the physician in charge should be instructed in the purpose, method and dangers of the treatment (much as in insulin treatment of diabetes) before attempting its use. It should be constantly pointed out to all concerned that the treatment cannot be expected to produce improvement of symptoms but appears merely to afford protection against serious future outbreaks. The danger of hemorrhage, and the steps to be taken should it occur, should be particularly emphasized. The patient should understand that the treatment apparently confers relative protection only while it is being adequately administered and that it will probably have to be continued the rest of his life.

2. Before starting the treatment, the physician in charge should assure himself that reliable determinations of the prothrombin time can be secured as often as necessary. The method of Shapiro and associates is considered as the most reliable one for the prothrombin time, and thromboplastin is the preparation used. In this method the clotting time of plasma diluted 1:8 is determined, as well as that of undiluted plasma. The normal prothrombin times obtained by this method are 18 ± 3 seconds for undiluted plasma and 40 ± 10 seconds for the diluted sample of plasma.

The prothrombin time is determined before treatment is begun, twice the first week, weekly for the next month, then every two or three weeks. Dosage of "dicumarol" is regulated to stabilize the prothrombin time of the undiluted plasma around thirty seconds. If the clotting time of whole plasma rises to forty seconds or that of diluted plasma to more than one hundred and twenty seconds, the dose should be omitted for at least four days, then begun at a lower level.

3. The usual initial dose of "dicumarol" is 150 mg. This is immediately cut down to 50 mg. daily, until a proper prothrombin time is reached. Fifty milligrams of the drug can then be given every other day until the prothrombin time drops below thirty seconds, when the dosage is increased again.

4. If hematuria occurs, administration of "dicumarol" *should* at once be stopped and the patient put to bed. A transfusion should be given within twenty-four hours. In stubborn cases repeated transfusions, as many as five, have been found necessary. Administration of vitamin K, even intravenously, has not seemed to be of immediate benefit.

Instruction in the use of "dicumarol" can be obtained from E. R. Squibb & Sons, 745 Fifth Avenue, New York. It must be emphasized that the use of "dicumarol" is still in the experimental stage.

B. Vasodilating Drugs (Other than Histamine): In many cases of multiple sclerosis there are constrictions of the retinal arterioles, with which there are usually associated scotomas and sometimes also a reduction in visual acuity. In most cases in which they were employed, fast acting vasodilating drugs have caused prompt, temporary reduction of the constrictions and of the size of the scotomas (sometimes to zero) and in several instances an increase of visual acuity as well, although the results were not entirely uniform. The inhalation of amyl nitrite almost uniformly produced general retinal vasodilation, and intravenous injections of papaverine hydrochloride sometimes appeared to produce general vasodilation and sometimes not.

Both drugs caused alleviation of scotomas. No clear-cut and indisputable effects in the course of the disease were observed as the result of orally administered vasodilating drugs over a period. The use of vasodilating drugs as a means of long term treatment is still in early experimental stages, despite the fact that under the experimental conditions previously mentioned such drugs, when administered so as to act rapidly and suddenly, may give transient beneficial results. The drugs now in oral use are aminophylline, "syntropan" N. N. R. and papaverine hydrochloride in tolerance doses.

As will be pointed out later, histamine is a valuable vasodilator. A great defect in its use in multiple sclerosis is the brevity of the period of vasodilatation. Theoretically, good vasodilation should be maintained twenty-four hours a day. Histamine may be given as a continuous infusion, but this limits the activity of the patient, a factor which may be disadvantageous if continued over a long period. When employed daily by brief infusion, histamine may be combined with the aforenamed orally administered drugs.

C. Histamine: Because frequent exacerbations and remissions are characteristic of this disease, evaluation of therapy is difficult. Under the circumstances, it is believed that histamine therapy cannot be adequately evaluated until more time has elapsed. Early diagnosis is important if any new treatment is to be tried and appraised. Later gliosis and irreversible changes take place that no type of treatment will alter.

The procedure which is employed at Mayo Clinic is as follows:

Add 2.75 mg. histamine diphosphate to 250 cc. isotonic sodium chloride solution. This solution is given intravenously by the drip method, beginning at a rate of approximately 20 drops per minute; however, the rate of administration depends entirely on the individual's tolerance. At no time should the patient experience any discomfort from the use of this drug. We limit the time for each treatment to a maximum of one and one-half hours and do not administer more than 250 cc. of the solution at a given treatment. In each instance, the response to treatment is watched carefully and the schedule adjusted accordingly. After daily treatment for a period of two weeks, the patient may notice some weakness and fatigue This is usually an indication of overtreatment, in which case we reduced the length of treatment or administer the solution only on alternate days. Some are under treatment for a period of weeks—others for a period of months. Patients are usually ambulatory. It is well known that histamine stimulates the gastric acids; hence, it is important that the patient have food in his stomach at the time of administration of the drug. This treatment is carried out without danger and is easily administered. Since we began this work in 1942, we have given over fifty-five thousand intravenous histamine injections without any untoward effects. Reactions have not occurred, even though we have administered as many as five hundred and sixty-one such injections to a given subject. Repeated injections do not change the patient's tolerance to the drug.

In man, histamine dilates the arterioles, venules and capillaries. Recently we have had occasion to study and to confirm these observations on the human brain. Furthermore, we have been able to demonstrate that histamine is the most powerful vasodilating agent available for increasing blood supply to the central nervous system; hence the rationale for its use in subjects with multiple sclerosis.

D. Sympathectomy: This form of treatment, founded on the vascular theory of multiple sclerosis, has apparently been abandoned.

COMMENT

The foregoing information has been prepared by members of and approved by the Medical Advisory Board of the National Multiple Sclerosis Society. It is designed to furnish to physicians the best information available at the present time, but the Society assumes no responsibility whatsoever for the accuracy or the completeness of the information or for any consequences of its use. The Society will be pleased to give any physician who requests it the benefit of any references where more details can be found and will be glad at all times to furnish any further information that may come to it as to the diagnosis of or the treatment of multiple sclerosis.

Clinical Notes, Suggestions and New Instruments

CUTANEOUS STAINS REMOVED WITH CHEMICAL DEPILATORIES

THEODORE CORNBLEET, M.D.
Chicago

Some valuable remedies for the treatment of the skin suffer from the disadvantage that they cause discoloration. Thus, solutions of potassium permanganate and of gentian violet medicinal are frequently used but leave unsightly blemishes that limit their usefulness. After their application to the nail weeks are required before growth is sufficient to displace them. It takes days for the discoloration of the skin to wear off.

There are a relatively few substances, such as the steroid hormones and several other materials, which can penetrate the epidermis of the skin. The rest are incapable of going beyond the keratin layer, usually not deeper than the outer two or three cell layers of the keratin. This can be demonstrated most easily visually with staining materials.

Most chemical depilatories take advantage of the fact that the alkaline sulfides are capable of softening and dissolving keratin. This protein material accounts in large part for the structure of the hair, the nails and the outer layer of the epidermis. Therefore, when one applies a depilatory for the removal of hair it acts not only on these keratin filaments but also on the surface of the skin between them. If the procedure is properly carried out with a good product, the hairs and a little of the outermost layer of the epidermis are removed without irritation. It takes longer to dissolve away the hair than it does to remove the outer two or three cell layers of the skin. Consequently, if one wants to remove merely the latter, less time is necessary and there is even less chance for irritation to develop. By test, it was determined that the removal of the outer cuticle, or that part discolored by staining materials, required only about half the time needed to dissolve hair. Thus the commercial chemical depilatories "neet," and "sleek" require about five minutes to remove cutaneous stains. It takes a little longer to clear the nails, but these more rugged structures can stand severer treatment. Cutaneous discolorations are thus easily and safely removed. For stains on hair it is better to make up a dilute solution of a sulfide, such as the calcium, which is to be applied for extremely short intervals and followed by rinsing. The procedure is to be repeated until one obtains the desired effect. Great care and some experience is needed to remove the stains and to leave the hair intact.

The preceding method has been found useful for the removal of adherent scales and crusts, which sometimes remain for a while after a dermatitis has subsided. This method must not be used on areas of active dermatologic lesions unless they are chronic and hyperkeratotic. It can be used on healed sites of impetigo or other dermatoses which remain discolored by a medicament. This method is applicable temporarily to some degree on areas discolored by saprophytic fungi, as in pityriasis versicolor and erythrasma. In some of my unpublished work sulfides have been found decidedly effective against yeasts and certain other fungi. In most of the superficial fungous infections the follicles become involved. The chemical depilatories cannot plumb these structures effectively in the short time that they are permitted to remain on the skin. Further observations, however, are being made to explore these possibilities. Pigmentary stains of the skin, such as those which follow an inflammation, are too deeply imbedded and cannot be removed by this method.

SUMMARY

Chemical depilatories have been proved effective in the removal of stains, such as those made by solutions of potassium permanganate and of gentian violet medicinal, from the skin and nails. Removing the very surface of the skin removes the stain.

1819 West Polk Street.

From the Department of Dermatology, University of Illinois College of Medicine, and the Cook County Hospital.

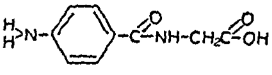
Council on Pharmacy and Chemistry

NEW AND NONOFFICIAL REMEDIES

The following additional articles have been accepted as conforming to the rules of the Council on Pharmacy and Chemistry of the American Medical Association for admission to New and Nonofficial Remedies. A copy of the rules on which the Council bases its action will be sent on application.

AUSTIN SMITH, M.D., *Secretary.*

PARA-AMINOHIPPURIC ACID.—4-aminobenzoylglycine.—The N-acetic acid amide of para-aminobenzoic acid.—$C_9H_{10}N_2O_3$.—M. W. 194.186. The structural formula of para-aminohippuric acid may be represented as follows:



Actions and Uses.—Sodium para-aminohippurate is excreted by the tubular epithelium of the kidneys in addition to being filtered by the glomerulus. It may be used to measure the effective renal plasma flow and to determine the functional capacity of the tubular excretory mechanism. To measure renal plasma flow, low plasma concentrations (1.0 to 2.0 mg. per hundred cubic centimeters) are necessary. At these concentrations 88 per cent of this compound is removed from the renal blood stream in a single circulation. The normal effective renal plasma flow is 697 ± 135.9 cc. per minute for men and 594 + 102.4 cc. per minute for women. This test cannot be applied to patients receiving sulfonamide compounds, because these develop color with the reagents used in the test.

To determine the functional capacity of the tubular excretory mechanism high plasma concentrations (above 60 mg. per hundred cubic centimeters) of sodium para-aminohippurate must be used. The normal mean value of the "tubular excretory mass" is 77.5 ± 12.9 mg. per minute.

Method of Application.—To Determine Effective Renal Plasma Flow: Sterile solution of sodium para-aminohippurate is injected intravenously in a volume sufficient to produce approximately 2 mg. of para-aminohippurate per hundred cubic centimeters of blood plasma. At this plasma level all the para-aminohippurate in the blood that passes through the kidney is removed and appears in the urine. The urine formed during a definite but relatively short period is collected, and the average amount of para-aminohippurate eliminated is calculated in milligrams per minute. This value divided by the para-aminohippurate content of the plasma in milligrams per cubic centimeter is equivalent to the number of cubic centimeters of plasma per minute that must have passed through the kidneys (effective renal plasma flow).

To Determine Tubular Excretory Mass: Sterile solution of sodium para-aminohippurate is injected intravenously in a volume sufficient to "saturate" the capacity of the tubular cells to excrete para-aminohippurate (above 60 mg. per hundred cubic centimeters of plasma), and the para-aminohippurate content of the plasma is determined in milligrams per cubic centimeter. The amount excreted in the urine is determined in milligrams per minute, this value including both glomerular filtration and tubular excretion. The glomerular filtration rate, using mannitol, a compound that is filtered only through the glomerulus, is determined in cubic centimeters per minute (see description of Sterile Solution of Mannitol). From the glomerular filtration rate and the para-aminohippurate content per cubic centimeter of plasma is calculated the amount of para-aminohippurate that was filtered through the glomeruli in one minute (cc./min. × mg./cc.). Then the total number of milligrams excreted in the urine per minute minus that amount filtered through the glomeruli per minute equals the amount of para-aminohippurate in milligrams per minute excreted by the tubules (tubular excretory mass).

Tests and Standards.—

Para-aminohippuric acid occurs as a white, crystalline powder. It melts at 197.5 to 199 C. It is sparingly soluble in water and alcohol and very slightly soluble in benzene, in chloroform and in ether.

Dissolve 0.1 Gm. of para-aminohippuric acid in 50 cc. of water. Add to 5 cc. of this solution 0.5 cc. of dilute hydrochloric acid and 0.5 cc. of 10 per cent sodium nitrite; then add 10 cc. of diluted ammonia solution containing 0.2 Gm. of betanaphthol: a red color develops in the solution.

Place 50 mg. of para-aminohippuric acid in a test tube and add 0.5 cc. of potassium iodide solution, followed by 2 cc. of water. Add 1 cc. of 5 per cent sodium hypochlorite solution: a red color develops in the solution *(distinction from para-aminobenzoic acid).*

Add 0.45 Gm. of para-aminohippuric acid, 0.2 Gm. of freshly fused sodium acetate, 0.25 Gm. of benzaldehyde and 0.75 Gm. of acetic anhydride to a 25 cc. Erlenmeyer flask. Place on a hot plate and shake the flask constantly until the material becomes liquid. Remove the flask immediately; cool, suspend in 10 cc. of water and filter. Wash the crystals with about 10 cc. of alcohol and then with 10 cc. of ether: the dry crystals melt at 236 to 238 C.

Dissolve 1 Gm. of para-aminohippuric acid in a mixture of 10 cc. of normal sodium hydroxide and 40 cc. of distilled water. Add to 25 cc. of the solution 5 drops of fresh normal sodium sulfide solution and acidify with 0.5 cc. of glacial acetic acid: no more darkening of the solution is produced than in that of a control to which 0.01 mg. of lead as lead nitrate has been added (p. 730, U. S. P. XIII).

Render 10 cc. of the original solution slightly alkaline and pass hydrogen sulfide through it for ten minutes: no precipitate appears.

Add 30 cc. of distilled water and 5 cc. of normal hydrochloric acid to 5 cc. of the original solution: the solution shows no more sulfate than corresponds to 0.2 cc. of fiftieth-normal sulfuric acid, when treated by the U. S. P. test (p. 729, U. S. P. XIII).

Dissolve 0.5 Gm. of para-aminohippuric acid in a mixture of 5 cc. of nitric acid and 15 cc. of distilled water: the solution shows no more chloride than corresponds to 0.1 cc. of fiftieth-normal hydrochloric acid when treated by the U. S. P. test (p. 729, U. S. P. XIII).

Dry 0.25 Gm. of para-aminohippuric acid, accurately weighed, at 110 C. for two hours: the loss in weight does not exceed 0.25 per cent.

Ash about 0.25 Gm. of para-aminohippuric acid, accurately weighed: the amount of residue is not more than 0.05 per cent.

Weigh accurately about 2.5 Gm. of para-aminohippuric acid. Dilute to volume in a 250 cc. volumetric flask. Transfer 50 cc. of the solution to a 250 cc. beaker; add about 20 Gm. of ice and 5 cc. concentrated hydrochloric acid and allow to stand for about three minutes. Titrate the cooled solution with tenth-molar sodium nitrite solution previously standardized against sulfanilic acid, using an outside indicator of starch-iodide paste. Each 1 cc. of tenth-molar sodium nitrite is equivalent to 0.0194 Gm. of para-aminohippuric acid: the para-aminohippuric acid content is not less than 98 per cent and not more than 102 per cent.

STERILE SOLUTION OF PARA-AMINOHIPPURIC ACID SODIUM SALT: The para-aminohippuric acid sodium salt solution is prepared by using equimolecular amounts of para-aminohippuric acid and sodium hydroxide in pyrogen-free distilled water. The *p*H is adjusted with citric acid, the solution made to volume, and the ampuls filled under nitrogen and sterilized by autoclave.

The *p*H of the ampul solution is not less than 7 or more than 7.6.

Dilute 10 cc. of the solution to volume in a 200 cc. volumetric flask. Transfer 50 cc. of the diluted solution to a 250 cc. beaker; add about 20 Gm. of ice, 5 cc. of concentrated hydrochloric acid and allow to stand for about 3 minutes. Titrate the cooled solution with tenth-molar sodium nitrite solution previously standardized against sulfanilic acid, using an outside indicator of starch-iodide paste. Each 1 cc. of tenth-molar sodium nitrite is equivalent to 0.0194 Gm. of para-aminohippuric acid: the para-aminohippuric acid content is not less than 98 per cent or more than 102 per cent.

SHARP & DOHME, INC., GLENOLDEN, PA.

Sterile Solution of Sodium para-Aminohippurate: 50 cc. ampuls. Each 50 cc. contains 10 Gm. of sodium para-aminohippurate, buffered to *p*H 7.0 with citric acid.

Para-Aminohippuric Acid (Reagent): 2 Gm. vials. For use in the preparation of standard solutions.

PENICILLIN (See New and Nonofficial Remedies, 1947, p. 144).

The following dosage forms have been accepted:

COMMERCIAL SOLVENTS CORPORATION, TERRE HAUTE, IND.

Tablets Crystalline Penicillin G Potassium: 100,000 units buffered with glycerides and sodium salts of fatty acids.

PREMO PHARMACEUTICAL LABORATORIES, INC., NEW YORK

Tablets Penicillin Calcium: 50,000 units and 100,000 units with calcium carbonate 0.25 Gm. as a buffer.

Troches Penicillin Calcium: 5,000 units.

CHAS. PFIZER & CO., INC., BROOKLYN

Crystalline Penicillin G Potassium: Bottles containing 100,000, 200,000 and 500,000 units and in bulk in bottles containing approximately one billion units.

NICOTINAMIDE (See New and Nonofficial Remedies, 1947, p. 514).

The following dosage forms have been accepted:

COLE CHEMICAL COMPANY, ST. LOUIS

Tablets Niacinamide: 100 mg.

BREWER & CO., INC., WORCESTER, MASS.

Solution Niacinamide, 100 mg. per cc.: 10 cc. vials. Preserved with 0.5 per cent chlorobutanol.

U. S. VITAMIN CORPORATION, NEW YORK

Solution Niacinamide, 50 mg. per cc.: 2 cc. ampuls.

AMINOPHYLLINE (See New and Nonofficial Remedies, 1947, p. 305).

The following dosage forms have been accepted:

BREWER & CO., INC., WORCESTER, MASS.

Solution Aminophylline: Ampuls 24 mg. in 10 cc.

Solution Aminophylline with Benzyl Alcohol 2%: Ampuls 48 mg. in 2 cc.

THIAMINE HYDROCHLORIDE (See New and Nonofficial Remedies, 1947, p. 506).
The following dosage forms have been accepted:

U. S. Vitamin Corporation, New York

Tablets Thiamine Hydrochloride: 1 mg., 3 mg., 5 mg. and 10 mg.

Solution Thiamine Hydrochloride, 10 mg. per cc.: 1 cc. ampuls and 5 cc. and 10 cc. vials. Preserved with 0.5 per cent chlorobutanol.

Solution Thiamine Hydrochloride, 50 mg. per cc.: 10 cc. vials preserved with 0.5 per cent chlorobutanol.

Council on Physical Medicine

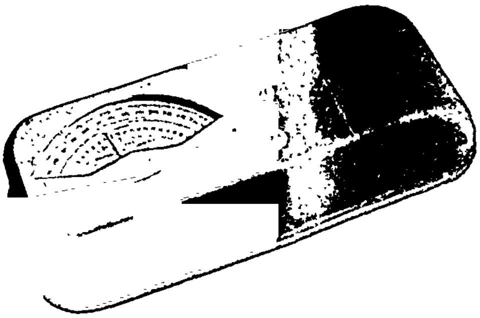
REPORT OF THE COUNCIL

The Council on Physical Medicine has authorized publication of the following reports. Howard A. Carter, *Secretary.*

COLLENS SPHYGMO-OSCILLOMETER ACCEPTABLE

Manufacturer: U. M. A., Inc., 56 Cooper Square, New York 3.

The Collens Sphygmo-Oscillometer is essentially a sphygmomanometer equipped with an aneroid manometer sensitive enough not only to permit readings of systolic and diastolic blood pressure by the oscillatory method but also to permit conclusions as to the patency of peripheral arteries. It does the latter by measuring the amplitude of the arterial pulsations at different cross sections of the upper and lower extremities. The instrument is enclosed in a sturdy metal compartment, which also has a space into which the necessary cuff, rubber tubing and inflating bulb can be tucked. The instrument as a whole is light and portable.



Collens Sphygmo-Oscillometer.

The instrument was examined in a clinic acceptable to the Council on Physical Medicine. It was considered satisfactory for diagnostic use. The directions seem to be well written and include a statement of the disease conditions in which the oscillometer may be expected to give information of diagnostic value.

The Council on Physical Medicine voted to include the Collens Sphygmo-Oscillometer in its list of accepted devices.

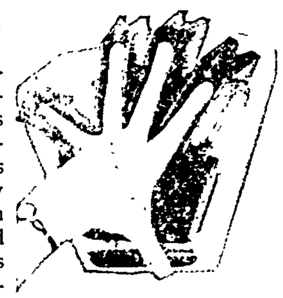
UNDERWOOD MANUFLEX ACCEPTABLE

Manufacturer: Underwood Manuflex Company, 2315 S. W. First Avenue, Portland, Ore.

The Underwood Manuflex is used for manipulating and stretching the joints of the fingers and the wrist.

The device consists of a base to which are attached four freely moving grooved molds. They are so shaped and connected that the base corresponds roughly to the palm of the hand, and the four molds fall into the position of the four fingers from the index to the smallest. Placing the molds in different positions by means of spaced pegs, many variations of movement and stretching of the fingers and wrist can be obtained.

A specimen of the device was examined in a clinic acceptable to the Council on Physical Medicine. The device was used in a wide variety of hand conditions, such as on hands involved by rheumatic arthritis, spastic paralysis, scars following burns, contractures following trauma and infection. When used under supervision of an occupational or physical therapist it was found to be of value in stretching the joints of the fingers, in correcting certain deformities of the fingers and wrist and in assisting in strengthening the intrinsic muscles of the hand. It can be used in a department for occupational therapy or for physical therapy.



Underwood Manuflex.

The folder issued by the company deals mainly with the possibilities of the device for musicians and athletes (e. g. basketball players). The only medical claims made are in a conservatively worded paragraph: "Effective in the treatment and relief of hand conditions resulting from wounds or disease which benefit by exercises for increased circulation and flexibility. Scar tissue, adhesions and swollen joints often come under this category." The fact that it is intended mainly for nonmedical groups is very evident. The promoter is cautioned that the acceptance of the Manuflex by the Council does not carry with it permission to exploit this fact in advertising to nonmedical groups such as musicians and athletes.

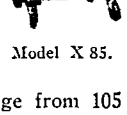
The Council on Physical Medicine voted to include the Underwood Manuflex in its list of accepted devices.

BURDICK CRYSTAL CONTROLLED DIATHERMY ACCEPTABLE

Manufacturer: The Burdick Corporation, Milton, Wis.

The Burdick Crystal Controlled Diathermy, Model X 85, is an apparatus mounted on four casters, equipped with both cable and drum for administration of diathermy to patients and designed to deliver a frequency of 13.66 megacycles per second. The frequency control devices with the unit are actuated by a piezoelectric quartz crystal and are stated to "maintain the frequency within a band width of plus or minus 0.05 per cent of 13.66 megacycles, regardless of how the controls are operated or applications to patient are made." It is also stated that "harmonic and spurious radiations are suppressed to a point well below the allowable limit of 25 microvolts per meter at a distance of 1,000 feet (304.8 meters)."

The firm assumes responsibility for noninterference with radio in case complaints are made. The Federal Communications Commission has awarded "type approval" no. D-471, and a copy of this type approval is on file in the office of the Secretary. Furthermore, the apparatus has been inspected by the Underwriters' Laboratories, Inc., and the device has been accepted for listing.



Model X 85.

The Model X 85 has a voltage tap switch with six positions for operation within tolerable limits of filament and plate voltage on line voltage from 105 to 125 volts. For maximum input of 350 milliamperes of plate current, with a line voltage of 117 volts and voltage tap switch on position four, the line input measures 9.50 amperes and 1,100 watts. The size of the cabinet is 36 cm. by 48 cm. by 54 cm. (14 by 19 by 21 inches). The unit weighs 150 kilograms (330 pounds).

The power output for the appliance in question has been measured in various ways by Council investigators using both the drum and the cable applicators, and the apparatus has been tested clinically. The apparatus conformed to all the requirements as set forth in the Council-adopted article, "Minimum Requirements for Acceptance of Diathermy Apparatus."

The Council on Physical Medicine voted to include the Burdick Crystal Controlled Diathermy, Model X 85, in its list of accepted devices.

with alcohol. Aside from its usefulness in withdrawal treatment, the technic seems about as illogical as the sugar treatment of diabetes or the morphine treatment of the opium habit.

With regard to a possible desensitizing action of alcohol given intravenously, little is known. Ethyl alcohol has never been considered to be antigenic, although some of its contaminants may be. In other countries scientists have studied the effects of injecting beer and wine under the skin of patients with chronic alcoholism. They reported that immunity did not develop and that untoward symptoms were absent after the pain subsided.

Estimates indicate that seven to ten years of heavy drinking are necessary to establish confirmed chronic alcoholism. At least an equal period of successful abstinence under medical observation is required before permanent cure can be claimed. Other aids to treatment will almost surely be developed. Slow or rapid withdrawal of patients from alcoholic beverages, adjuvant medical treatment and psychotherapy for the underlying personality disorder constitute present day approved therapy. "Alcoholics Anonymous" have invoked the additional factors of spiritual inspiration and mass psychology.

YOUR DIRECTORY INFORMATION CARD

Preparations are now being made to publish the new eighteenth edition of the "American Medical Directory." The last previous edition of the Directory was issued late in 1942; wartime restrictions and the shortage of paper and labor have prevented any intervening issues. About November 15, a directory card will be mailed to every physician in the United States, its dependencies and Canada, requesting information to be used in compiling the new Directory. Physicians who receive an information card should fill it out and return it promptly whether or not any change has occurred in any of the points on which information is requested. Physicians should also fill out the right half of the card, which information will be used exclusively for statistical purposes. Even if you have sent in similar information recently, mail the card promptly to insure the accurate listing of name and address. There is no charge for publishing the data, nor are physicians obligated in any way. The Directory is one of the most important contributions of the American Medical Association to the work of the medical profession in the United States. In it, as in no other published directory, may be found dependable data concerning physicians, hospitals, medical organizations and activities. Full information on medical schools, specialization in the fields of medical practice, memberships in special medical societies, tabulation of medical journals and libraries and, indeed, practically every important fact concerning the medical profession in which any one might possibly be interested is also included. If you fail to receive one of these Directory Information cards by December 1, write at once to the Directory Department requesting that a duplicate card be mailed.

LEUKERGY, THE CLUMPING OF WHITE CELLS IN INFLAMMATION

American scientific missions to Europe have returned with a few reports of effective research work in the occupied and devastated countries. The medical mission to Poland for the United Nations Relief and Rehabilitation Administration, for example, returned with a series of contributions from Polish medical scientists. Some of these have recently been published. Among them is a report by L. Fleck and Z. Murczynska on the clumping of white blood cells in cytologically homogeneous groups in inflammation.[1] This condition is called "leukergy." It was found that leukergy increases in infectious diseases. The phenomenon appears to be associated with the agglutination of platelets. Ordinarily the process is slow, taking three to five hours, and involves only a small portion of white cells. In such infectious diseases as typhus, pneumonia or sepsis the process is intensified, and practically all the leukocytes are clumped in groups of 8 to 20 cells within ten to twenty minutes. This increased leukergy persists during the stage of convalescence. The clumping of lymphocytes becomes more definite with decrease of temperature, whereas neutrophils clump more readily in fever. The authors suggest that serologic factors may be involved. A study of these factors may lead to further understanding of the inflammatory process.

LOCAL HEALTH UNITS

Under the auspices of the American Public Health Association a conference to consider effective ways of improving local health services was attended recently by delegates of sixty-five organizations, including the American Medical Association. The role of the local health department, the state health department and voluntary citizen organizations were discussed. Throughout the conference the six basic functions of a local health department that were set forth in the report by Emerson and Luginbuhl [1] were emphasized. What each organization can provide for the community must be determined by careful study. One plan cannot be applied nationally with the hope that it will be equally effective for all communities. County and state medical societies should take active parts in all planning. The House of Delegates of the American Medical Association has expressed its approval of plans to cover the population by local units of health jurisdiction. The members of the medical profession must participate and lend sufficient aid to achieve complete local health protection in cooperation, not competition, with medical practice.

Washington Letter

(From a Special Correspondent)

Oct. 30, 1947.

Dr. Hawley Reports Increase in Alcoholism Among Veterans

Dr. Paul R. Hawley, medical director, Veterans Administration, stated in a speech before the Southern Governor's Conference at Asheville, N. C., that chronic alcoholism is increasing among veterans "by leaps and bounds." He said that in two thirds of 10,000 patients expected to require treatment this year for alcoholism the condition involved pure uncomplicated alcoholism and had nothing to do with mental illness. The agency also announced that it plans a special research project on fertility problems of the 1,600 paraplegics of World War II. Rejected was a proposal for setting up an artificial insemination clinic for married veterans who had suffered loss of natural sexual function. Dr. Hawley announced the transfer of Dr. Robert C. Cook, deputy medical director since January 1946, to the managership of the Veterans Hospital at Fort Logan, Colo.

Science, Research and Public Policy

The fourth report of a five volume series, "Science and Public Policy," issued by the President's assistant, John R. Steelman, as head of the President's Scientific Research Board, stresses that the shortage of scientific personnel is dangerous to national welfare and security. It is attributed to heavy postwar demand for scientists and severely reduced wartime training of potential scientists. Mr. Steelman said it is "of the utmost urgency that steps be taken to increase and improve our scientific manpool."

In the last of his five reports to President Truman Mr. Steelman declared that national expenditures for research, including government expenditures for this purpose, should eventually be tripled. The report was titled "The Nation's Medical Research," and it warned that there is a critical shortage of research workers in medicine and allied subjects. The report pointed out that some of the most prevalent diseases are receiving little attention in federal medical research programs, among them heart disease, influenza, rheumatism, kidney disease, sinusitis and the common cold. The 118 page report recommended that the nation as a whole, government, industry, universities and other private groups, triple outlays for research as quickly as possible with an objective of spending $300,000,000 annually by 1957. Mr. Steelman declared that most of this expansion must come from public funds but that federal support for research should supplement and not replace other financing.

Increased Basic Scientific Research Need Stressed

W. W. Waymack, one of the five members of the U. S. Atomic Energy Commission, told a Unitarian Association audience here that the present wave of nationalism may cut the United States off from foreign discoveries in basic science on which it has long depended. He said that it is vital for America to strengthen herself in basic scientific research. "We have a nucleus of unquestioned genius in basic research. But up to now the American superiority has been in applied science, not in what is called basic or pure scientific research—the search for new fundamental knowledge about the nature of things, regardless of whether anybody can see an immediate practical application or not. Yet, it is in that field that the great advances are made. Let's be blunt about it—there is today no assurance that basic science is going to be as freely international as it used to be. There is danger, if the world situation deteriorates, that a wave of alarmed nationalism will for the first time engulf science, too."

Health Service Studying Russian Treatment for Cancer

The National Cancer Institute of the U. S. Public Health Service is reported to have obtained an original manuscript describing in detail the Russian "KR" treatment for cancer and to have procured from London the same strain of organism as that used by Klyueva and Roskin in their reported successful treatment. Institute research workers are endeavoring to check the claims made by Nina Klyueva and Gregori Roskin in their treatment of cancer.

Medical Supplies Stocked by War Department

The War Department revealed that among its vast stockpile of strategic materials being accumulated in the event of an international emergency are medical supplies. The stockpiling plan, part of an industrial preparedness program, will cost $2,100,000,000 over a five or six year period.

Sells Entire Sulfonamide Stock

The War Assets Administration announced here that it was offering its entire $2,500,000 stock of sulfonamide drugs in an "inventory clearance" sale beginning October 27.

Limb Manufacturers

Delegates to the thirtieth annual convention of the Orthopedic Appliance and Limb Manufacturers' Association were so pleased with their deliberation here that members decided to hold their 1948 convention in the capital of the United States.

Coming Medical Meetings

Conference of State Medical Society Secretaries and Editors, Chicago, A.M.A. Headquarters, Nov. 7-8. Dr. George F. Lull, 535 N. Dearborn St., Chicago 10, Secretary.

American Academy of Allergy, St. Louis, Hotel Jefferson, Dec. 15-17. Dr. Theodore L. Squier, 425 E. Wisconsin Ave., Milwaukee 2, Secretary.

American Academy of Dermatology and Syphilology, Chicago, Palmer House, Dec. 7-11. Dr. Earl D. Osborne, 471 Delaware Ave., Buffalo, N. Y., Secretary.

American Academy of Pediatrics, Dallas, Texas, Dec. 8-11. Dr. Clifford G. Grulee, 636 Church St., Evanston, Ill., Secretary.

American Association of Railway Surgeons, Chicago, Nov. 23-25. Dr. Raymond B. Kepner, 547 West Jackson Boulevard, Chicago 6, Secretary.

American Otorhinologic Society for the Advancement of Plastic and Reconstructive Surgery, New York, Nov. 13. Dr. Norman N. Smith, 291 Whitney Ave., New Haven 11, Conn., Secretary.

American Society for the Study of Arteriosclerosis, Chicago, Hotel Knickerbocker, Nov. 2-3. Dr. O. J. Pollak, Wilmington General Hospital, Wilmington 14, Delaware, Secretary.

American Society of Anesthesiologists, New York, Hotel New Yorker, Dec. 4-5. Dr. Curtiss B. Hickcox, 745 Fifth Ave., Room 1503, New York 22, Secretary.

American Society of Tropical Medicine, Atlanta, Ga., Dec. 2-4. Dr. Norman H. Topping, National Institute of Health, Bethesda 14, Md., Secretary.

Association of Military Surgeons of the United States, Boston, Hotel Statler, Nov. 13-15. Col. James M. Phalen, Army Medical Museum, Washington 25, D. C., Secretary.

New York State Association of Public Health Laboratories, Albany, Nov. 7. Miss M. B. Kirkbride, New Scotland Ave., Albany 1, Secretary.

Post Graduate Medical Assembly of South Texas, Houston, Texas, Coliseum, Dec. 1-3. Dr. E. Trowbridge Wolf, 229 Medical Arts Bldg., Houston, Texas, Secretary.

Puerto Rico, Medical Association of, San Juan, Dec. 10-14. Dr. Jeramfel Cordero, Box 3866, Santurce, Secretary.

Radiological Society of North America, Boston, Nov. 30-Dec. 5. Dr. Donald S. Childs, 607 Medical Arts Bldg., Syracuse 2, N. Y., Secretary.

Seaboard Medical Association of Virginia and North Carolina, Virginia Beach, Va., Dec. 2-5. Dr. Clarence Porter Jones, 3117 West Ave., Newport News, Va., Secretary.

Southern Medical Association, Baltimore, Nov. 24-27, Mr. C. P. Loranz, Empire Bldg., Birmingham 3, Ala., Secretary.

Southern Surgical Association, Hollywood, Fla., Dec. 9-11. Dr. Alfred Blalock, Johns Hopkins Hospital, Baltimore 5, Secretary.

Southwestern Medical Association, Phoenix, Ariz., Hotel Westward Ho, Nov. 6-8. Dr. Louis W. Breck, 116 Mills St., El Paso, Texas, Secretary.

Western Surgical Association, Colorado Springs, Broadmoor Hotel, Dec. 4-6. Dr. Warren H. Cole, 1853 West Polk St., Chicago 12, Secretary.

JOINT COMMITTEE FOR THE COORDINATION OF MEDICAL ACTIVITIES

Report of Meeting in Chicago, August 16

The Joint Committee for the Coordination of Medical Activities met in the Board Room of the American Medical Association Building in Chicago on Saturday, Aug. 16, 1947. The meeting was called to order by the Chairman, Dr. Ernest E. Irons, at 10 a. m. Members and liaison members present were:

Dr. Arthur W. Allen, Boston. (American College of Surgeons)
Dr. Donald G. Anderson, Chicago. (Secretary, A.M.A. Council on Medical Education and Hospitals)
Brig. Gen. George E. Armstrong, Washington, D. C. (Office of the Surgeon General, U. S. Army)
Dr. Walter L. Bierring, Des Moines, Iowa. (Federation of State Medical Boards)
Mr. George W. Cooley, Chicago. (A.M.A. Council on Medical Service)
Dr. W. Palmer Dearing, Washington, D. C. (U. S. Public Health Service)
Dr. Warren F. Draper, Washington, D. C. (American Medical Association and American Red Cross)
Capt. William E. Eaton, Washington, D. C. (American Medical Association and U. S. Navy)
Dr. Charles H. Evans, Warrenton, Ga. (American Pharmaceutical Association)
Dr. Robert P. Fischelis, Washington, D. C. (American Pharmaceutical Association)
Dr. Johnson F. Hammond, Chicago. (American Medical Association)
Dr. Elmer L. Henderson, Louisville, Ky. (American Medical Association)
Mr. Thomas A. Hendricks, Chicago. (A.M.A. Council on Medical Service)
Dr. Hugo F. Hullerman, Chicago. (American Hospital Association)
Dr. Ernest E. Irons, Chicago (American College of Physicians)
Dr. Victor Johnson, Rochester, Minn. (A.M.A. Council on Medical Education and Hospitals)
Dr. George F. Lull, Chicago. (American Medical Association)
Dr. J. J. Moore, Chicago. (American Medical Association)
Dr. H. B. Mulholland, Charlottesville, Va. (A.M.A. Committee on Rural Medical Service)
Dr. James E. Paullin, Atlanta, Ga. (American Medical Association)
Col. Paul I. Robinson, Washington, D. C. (Office of the Surgeon General, U. S. Army)
Rev. A. M. Schwitalla, S.J., St. Louis. (Catholic Hospital Association)
Dr. R. L. Sensenich, South Bend, Ind. (American Medical Association)
Dr. E. R. Serles, Chicago. (American Pharmaceutical Association)
Dr. H. H. Shoulders, Nashville, Tenn. (American Medical Association)
Mrs. M. V. Shuler, Chicago. (A.M.A. Bureau of Information)
Miss Mary Switzer, Washington, D. C. (Federal Security Agency)

CHANGES IN MEMBERSHIP

The Chairman announced the appointment of Dr. Walter L. Palmer, Chicago, as a member of the American College of Physicians Committee to take the place of Dr. LeRoy H. Sloan, resigned.

There was presented a communication addressed to the Chairman by Major Gen. R. W. Bliss, Surgeon General of the U. S. Army, in which it was stated that Lieut. Col. William N. Piper had been transferred from the Office of the Surgeon General and that Brig. Gen. George E. Armstrong, Deputy Surgeon General and Col. Paul I. Robinson, Chief of Personnel, had been appointed to represent the Office of the Surgeon General in the liaison membership of the Joint Committee.

The Chairman announced that the American Pharmaceutical Association had been invited to appoint representatives to liaison membership in the Joint Committee, and that Dr. E. R. Serles of Chicago, president, Dr. Charles H. Evans of Warrenton, Ga., chairman of the Professional Relations Committee, and Dr. Robert P. Fischelis, secretary of the American Pharmaceutical Association, had been appointed and were in attendance.

Father Schwitalla asked permission to bring an "understudy" to the next meeting in the person of Father John P. Flanagan, who has recently been appointed Executive Director of the Catholic Hospital Association. The Committee concurred in the expression of the Chairman that Father Flanagan would be more than welcome but sincerely hopes that Father Schwitalla will retain his own membership.

REPORT TO THE HOUSE OF DELEGATES

The Chairman presented the annual report of the Joint Committee for the Coordination of Medical Activities, which he had submitted to the House of Delegates of the American Medical Association at its annual session in June, and read the following adopted report of the reference committee to which it had been referred:

> "The reference committee believes that the work of this Committee in acting as a liaison with all medical services is invaluable. It strongly urges that the Committee continue to function and recommends the adoption of the report.

The Joint Committee, on motion duly seconded and carried, approved the annual report as prepared by the Chairman. (This report was printed in THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, June 21, p. 715.)

HOSPITAL RESIDENCIES AND GRADUATE EDUCATION

Dr. Donald G. Anderson, successor to Dr. Victor Johnson as Secretary of the Council on Medical Education and Hospitals, submitted the following statement on the present status of hospital residencies and graduate education:

During the past year the number of residencies and fellowships approved by the Council on Medical Education and Hospitals of the American Medical Association has increased from 8,930 to 12,003, a gain of 3,073. In 1941 there were only 5,256 approved residencies, so that the current figure represents an increase of 6,747 residencies, or 128 per cent over the peak prewar figure. There is no way of accurately determining how far this great expansion of training opportunities has gone toward meeting the demand for residencies. Very few unfilled residencies have been reported to the Council office; on the other hand, the number of physicians who are seeking information about open appointments has dwindled to handful. It probably would be fair to estimate that most physicians seeking residency training have been able to secure satisfactory appointments although at times only after some delay. Until there is clear evidence tha the need for this type of training has been met fully, it would appea desirable to continue to strive to expand the residency program to th capacity of the hospitals and their personnel for giving effective training A steady flow of applications for approval of newly created residencies i still coming in to the Council office, so that a further increase in th total number of residencies during the coming year definitely can b expected.

In the field of graduate education represented by graduate assemblie and postgraduate and continuation courses, 1,644 courses were offere during the past year. Of these, 239 were short review courses of fiv days' duration or less, 1,291 were courses of more than five days' duratio and 14 were classified as clinical conferences or graduate assemblies. Th steadily growing popularity of such courses can be judged from the fac that in two years the annual attendance has increased from 18,000 t 59,000. At the moment there is no evidence of any slackening of intere in providing such training since more than 800 courses already have bee listed for the period July 1 to Dec. 30, 1947.

Following is a résumé of the discussion on Dr. Anderson' presentation:

The trend in the increase of hospital residencies is general througho the country and not confined particularly to the larger communities. Th Council on Medical Education and Hospitals has no definite informatio as to any tendency on the part of residents to drift from place to plac because of dissatisfaction. In almost every field the present availab residencies are such as to qualify the men for certification by specialt boards; after the Council passes on a residency, it is submitted to t specialty board concerned for approval, and the Council does not gi final approval or list a hospital as approved for residencies in specialti unless it is also approved by the specialty boards; a few of the boar do not cooperate with the Council in this connection.

When a man takes a residency in a hospital approved by the Coun on Medical Education and Hospitals, nothing is said in his appointm as to whether the residency is for one, two or three years, and in th cases in which a board requires a three year residency it is up to candidate to obtain those three years wherever he can. It is not requi that a three year residency be continuous in the same institution. Sc hospitals consider themselves capable of providing only one year residency training and say that if they cannot get residents unless they provide three year residencies, they may be obliged to consider dropping their residencies altogether. However, although the student is prone to throw the burden on the hospital, it would appear that if he has one year at one hospital, one at another and so on, the specialty boards would be satisfied. Such migratory residencies may not be the best thing for the person in that by serving as resident in perhaps three different hospitals, he might merely be repeating his work each year and thus gain little growth. One of the best examples of a residency of limited duration is in orthopedic surgery in a children's hospital; a man seeking certification in orthopedic surgery would not want to spend his whole time in a children's hospital; it is that sort of limitation which is involved in many institutions where only one year of residency is allowed.

Father Schwitalla asked for opinions as to the necessity for agreement between universities and specialty boards and also asked if there has been any coordinate attempt to harmonize efforts of universities with board requirements. He thought there probably is room for interchange of opinion and perhaps, some time in the future, conferences might be desirable between schools—graduate schools and universities that are recognized as clinical schools—and the specialty boards. Dr. Johnson thought that if a hospital had a program leading to a master's degree, such conferences probably would be acceptable. As an illustration of what he had in mind that should be clarified, Father Schwitalla presented the following example: A man has spent one or two years in an approved residency in a nonuniversity hospital; in another hospital, perhaps in the same community, members of the university faculty are doing the teaching and the resident wants to transfer to the university program. However, if he does so, he is not allowed full credit for the year, or two years, in the first hospital because the university refuses to recognize the control of the residency in that hospital; the same thing sometimes applies when a man transfers from one university hospital to another; the men concerned are mostly those who already have an M.D degree and are working toward an M.A. or Ph.D. degree.

It was Dr. Johnson's opinion that the specialty boards would have no concern over that sort of situation, that it is entirely an academic matter and that the boards would not be even slightly concerned in cases in which a man is working for a degree other than the M.D. Dr. Irons agreed with Dr. Johnson and saw no need for the specialty boards to be concerned.

LICENSURE

Dr. Bierring offered the following report on the status of medical licensure with particular reference to licensure of graduates of foreign extramural schools:

Three of the extramural European *schools* with which the United States licensing boards have had reason to be concerned are located in Scotland. They have been in existence for a considerable number of years and have been, principally, clinical schools in which the faculty is comprised of members of the faculty of the University of Glasgow and the University of Edinburgh *and, in* a few instances, of St. Andrews University and also of Fellows of the Royal College of Surgeons and the Faculty of Medicine of Glasgow University. The teaching of anatomy and the basic sciences in these schools always has been below that of university training. While there has been no special inspection of these schools, a great deal of attention has been paid them, particularly by the Association of American Medical Colleges.

Since 1939 the tendency on the part of the American licensing boards has been not to accept for licensure graduates of these schools. However, *since 1944* such graduates have been accepted for licensure in New York state and as a result they are now applying in other states for reciprocity. In some few instances, they have been accepted because the states concerned have reciprocity agreements with New York. The general tendency at the present time is to look *more closely into the credentials of these* graduates and not to admit them to licensure. An item in The Journal of the American Medical Association for August 9 (p. 1254) stated that a newly appointed assistant director in the headquarters of the United Nations World Health Organization is a graduate of St. Andrews and has a degree of Doctor of Public Health. In Great Britain such graduates receive no degree; they are admitted to the Conjoint Examination Board of England and the Triple Qualification Board of Scotland, are placed on the Register to practice and are designated as Licentiate of the Royal College of Physicians and Member of the Royal College of Surgeons.

Another matter troubling licensing bodies at present is the tendency toward development of more state boards of examiners in the basic sciences. There are now nineteen such boards in eighteen states and the District of Columbia. One of the main purposes in the original establishment of these boards was *to limit* the licensure of improperly educated practitioners of the healing arts. Only six of the basic science boards accept the certificate of the National Board of Medical Examiners, and five of them have no reciprocal argreements with other boards. The problem with respect to medical licensure is that while the basic purpose of these boards was to determine a general knowledge of the basic sciences in order to qualify an applicant for admission to examination for licensure *in the healing* arts, gradually they have come to be agencies that actually determine medical licensure. A year ago a prominent physician said that the basic science examination was the "alpha of the omega of medical licensure." An osteopath or a chiropractor may be a member of a basic science board. There are three states in which a Doctor of Veterinary Medicine is a member; in five states an osteopath is a member and in four states a chiropractor is a member.

In response to a question from Miss Switzer, Dr. Bierring said that there have been graduates of the best medical schools who have failed to pass the basic science board examinations, largely because of the nonmedical examiners, and that another difficulty is in the methods of grading, which vary from subject passing grades of 70 to 75 per cent for a general average; a number of states require 75 per cent in each subject—the board in New Mexico requires 85 per cent passing grade and 75 per cent in each subject!

Dr. Johnson expressed the opinion that the basic science board constituted another barrier to the movement of physicians from one state to another and that the recent graduate does not have much trouble in the examinations but a graduate of twenty or thirty years ago is often in difficulty.

In reply to a question by Dr. Moore, Dr. Bierring stated that by action taken at a meeting of the Federation of State Medical Boards a year ago and confirmed again in February 1947 no medical graduates of foreign schools, except those of the university medical schools of Great Britain, would be considered for admission to examination for licensure unless they had taken an additional year of training in this country.

THE GENERAL PRACTITIONER

REPORT OF SUBCOMMITTEE ON SPECIALTY BOARD FOR GENERAL PRACTITIONERS

Dr. Sensenich, a member of the Subcommittee, presented the following:

The meeting of county medical society officers in Atlantic City at the time of the annual session of the American Medical Association, the so-called Grass Roots Conference, afforded a good perspective of the present situation in the general practice of medicine. To this meeting were invited the officers of the county medical societies, the organizations which are *the backbone of the organized medical profession in this country.* More than 300 physicians from widely distributed areas were in attendance. The desirability of a specialty board for general practitioners was discussed at some length, and it is doubtful that the movement to that end is gaining any particular strength. The Indiana Board of General Practice, the pioneer in the field, was established with excellent motives and outlines; it is still very young and it is not yet definite as to what its place in medicine is or as to what should be done to carry out its objectives. However, the position of the general practitioner with respect to his place *in the hospital is acute. It does not appear from study and observation* that the general practitioner himself is particularly interested in the establishment of a specialty board which will "certify" him. He is interested, however, in the position that he is a member of the only group in the whole medical profession that is not organized for itself and he feels himself to be on the defensive and unable to protect himself. This feeling will stimulate some kind of united effort on the part of general practitioners and may add to the tension that is evident in their hospital relationships. Out of all this a certifying board, or at least some machinery *for recognizing superior work, might evolve, a board to improve the* standards of the general practitioner and not too much involved in attempts to protect his selfish interest.

Some kind of general practitioners' organization is inevitable. It is not sure that that would improve the situation at all, but they are sufficiently distressed and unhappy to try almost anything. The danger lies in the fact that such an organization, will be more concerned with protecting the group against what they believe to be inequities and disadvantages suffered only by their group.

SECTIONS ON GENERAL PRACTICE IN HOSPITALS

Dr. Anderson informed the Committee as follows regarding the activity of the Council on Medical Education and Hospitals with respect to the establishment of general practice sections in hospitals:

The Council on Medical Education and Hospitals has been active in advancing the development of general practice sections in hospitals. At the meeting of the House of Delegates of the American Medical Association in June, the Council presented a supplementary report which reviewed the policy of the Council, the Advisory Board for Medical Specialties and *the House of Delegates with respect to the appointment of general practitioners* to hospital staffs. This report was later published in The Journal, June 21, page 711.

In the report it was pointed out that any policy of limiting staff appointments to physicians certified by specialty boards or holding membership in certain special societies is contrary to the principles of the Council and of

> the Advisory Board for Medical Specialties. The report went on to cite the action of the House of Delegates in 1946 when it passed a resolution encouraging hospitals to establish general practitioner sections. This resolution specifically stated that the creation of such services would not prevent hospitals from being approved for the training of interns or residents.
>
> The Council requested the authorization of the House of Delegates to amend the section of the Essentials of a Registered Hospital dealing with the establishment of staff sections so as to include specific mention of general practice sections. This amendment was approved by the House of Delegates.
>
> Reprints of the supplementary report and copies of the revised Essentials of a Registered Hospital have been sent to every one of the Council's registered hospitals and to all the hospital associations. Also included were reprints of an article by Dr. M. H. Miller describing the operation of a general practice section in a large general hospital over a period of eight years.
>
> In addition to these activities, the Council has been active in advising physicians and hospitals seeking information about the establishment of general practice sections in specific hospitals. In order that it may be prepared to render maximum assistance in this respect, the Council is trying to collect detailed information regarding the working arrangements in hospitals that have already established general practice sections. In conducting the annual census of registered hospitals this fall, the Council will secure information as to how many hospitals have established general practice sections. The data obtained in this way should be helpful in determining how much progress is being made in securing the place of the general practiitoner in the hospitals of this country.

During the discussion and in reply to various questions, Dr. Anderson stated that a general practice section is simply the part of the hospital where the general practitioner enjoys staff membership and has the privilege of bringing his patients. It is more an administrative than a physical set-up. The Council on Medical Education and Hospitals has discussed but has not succeeded in finding a satisfactory definition of a general practice section or of general practice itself. For the present, at least, it would seem wise to hold to general principles such as that the general practitioner should be allowed to do whatever he is qualified to do. As far as a patient is concerned, a general practice section in a hospital means that if he is being taken care of by a general practitioner, that practitioner can continue to take care of him in the hospital.

Dr. Bierring asked if it should not be the purpose of the Council to develop a standard that the general practice section is the part of the hospital which should be the principal service in the hospital from which reference to special services should be made, and Dr. Anderson thought the Council certainly should encourage such a development.

Dr. Sensenich suggested that it might be advantageous if, for certification, the specialty boards would require a certain amount of general service either inside or outside a hospital on some basis that would carry out Dr. Bierring's idea. Father Schwitalla asked whether Dr. Bierring implied that the functions of the general practitioner and the diagnostician are identical, and Dr. Bierring stated that to be his opinion. Father Schwitalla said that the direction the general practice development is taking in some hospitals is not exactly the direction pointed out by Dr. Bierring, but that perhaps the whole tension could be relieved if Dr. Bierring's plan could be maintained.

Dr. Bierring expressed the opinion that the general practitioner of the future is going to be able to recognize the conditions that require his services, that he is going to take care of 75 per cent of all illnesses and that the young man now coming up, with two years of rotating internship and possibly two years of residency training in general practice, is going to be the family physician of the future.

REPORT ON ACTION OF THE HOUSE OF DELEGATES OF THE AMERICAN MEDICAL ASSOCIATION

Dr. Shoulders presented a statement as follows:

> During my two years as President-Elect and President of the American Medical Association, I was the recipient of many complaints that the medical profession was not giving the best service to the people. One criticism which I heard many times was that the medical student during his education is entirely under the influence of specialists, that his training is all to the end that he may be qualified to take a specialty board examination. It seemed to me that a committee of the American Medical Association might be appointed which would be widely representative of the profession and which might conduct a study and present a report that could be very helpful. My entire thought in making a recommendation to that effect to the House of Delegates was that by this means it might be discovered whether or not the complaints have any justification in fact. The proposed committee could: (1) define the term "general practitioner," or "general physician," on a functional basis; (2) determine whether or not there is need for a large increase in the number of medical graduates and, if so, its extent; (3) study the present program of medical education and training, both undergraduate and postgraduate, to determine whether or not the content and administration of the program is properly adjusted to the present day needs of the people; (4) study the possibility and feasibility of utilizing smaller community hospitals in a program for the training of general practitioners and the possibility of approving such institutions for such training when a teaching program is properly organized and administered; (5) study the means by which communities in need of additional services may be aided; (6) study such other questions as the committee itself may determine to be necessary in arriving at sound conclusions concerning the entire field of medicine, and (7) propose a long range program designed to overcome present insufficiencies and to meet future needs.
>
> The House of Delegates approved my recommendation, and I understand from Dr. Irons that the committee will be appointed by the Board of Trustees at its September meeting.

Miss Switzer remarked that there are many efforts on the part of both public and private agencies in special fields—as, for instance, in the Federal Security Agency, the well financed projects in cancer research and mental hygiene—which seek to encourage medical schools to give emphasis in their curriculums to special subjects, and that this prodding for orientation of medical education on the special side should be taken seriously into consideration in any study that is pointed to improve the education of a medical student who may become a general practitioner; if the funds available for special projects could be used to improve education for general practice, the natural result would be to bring eventual improvement in the practice of specialties.

Dr. Lull discussed the economic side of the matter, saying that a man who is certified as a specialist is supposed to limit his practice to that specialty and eventually he is going to find that he cannot make a good living because the country can absorb only so many specialists.

Dr. Johnson spoke in behalf of the specialty boards: It is clear that no one knows how to meet the situation, but making the American boards the whipping post ought to be avoided. The boards have done a fine job. On several occasions the whole blame for the present situation has been laid at the door of the boards; that is loose thinking and entirely unwarranted.

AMERICAN ACADEMY OF GENERAL PRACTICE

Dr. Bierring presented a report which he had prepared, after some investigation, on the newly organized American Academy of General Practice.

After discussion, the Joint Committee adopted a motion that Dr. Bierring inform Dr. Davis, president of the Academy, that the House of Delegates of the American Medical Association has authorized the appointment by the Board of Trustees of a committee to study the problems of the general practitioner and of general practice, and that this Joint Committee will be glad to recommend that the conclusions of the new committee be transmitted at the proper time to Dr. Davis.

REPORT OF SUBCOMMITTEE ON LEGISLATION FOR A NATIONAL DEPARTMENT OF HEALTH

Miss Switzer reported for the Subcommittee on Legislation for a National Department of Health as follows:

> The original Taft Bill, S. 140, was somewhat amended to eliminate the professional qualifications required of the three undersecretaries, to create the three divisions—health, education and security—and to charge each of the three undersecretaries with special responsibility for each division. The Bill was reported out of committee but did not come to a vote in the Senate. It probably will come to a vote early in the next session of Congress. Then, of course, it has to go to the House.
>
> The relation of S. 140 to H. R. 545 would be very important if the latter should retain its provision for the establishment of an independent health agency. If S. 140 is enacted into law, it is probable that the health agency provisions of H. R. 545 will be eliminated.
>
> The chances of a purely professional person being in charge of the proposed Division of Health would be about 50-50, depending on the personal preference of the President making the appointment. If the present programs remain more or less as they are, the present situation probably will not be changed much, but if there should be an elaborate medical care program, it is reasonable to expect some changes.

The Chairman thanked Miss Switzer for her report and stated that the subcommittee would be continued to report when there are further developments.

Permission was requested by the Chairman, and was granted, for the continuation of the subcommittees which reported at this meeting so that further progress reports on hospital residencies, licensure, general practice and so on can be heard at the next meeting.

HOSPITAL SURVEY AND CONSTRUCTION PROGRAM

The Chairman asked Miss Switzer to inform the Joint Committee regarding the progress of activity authorized under the Hill-Burton Hospital Survey and Construction Act, which she did as follows:

> Shortly after the last meeting of this Joint Committee, followed by a meeting of the Federal Hospital Council in Washington, D. C., Mr. Graham Davis of the American Hospital Association, a member of the Joint Committee, discussed with me his concern that in the state advisory councils provided for under the Hospital Survey and Construction Act there is not enough leadership taken by the state medical societies. I have found that more has been done than perhaps Dr. Davis or I realized. I think Dr. Davis felt that some direct recommendation to state and county medical societies as to what they might do in connection with the advisory councils would be helpful. Perhaps something could be printed in THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION to call special attention to the necessity for greater activity on the part of the state associations.
>
> A pamphlet summarizing the law and regulations governing the Hospital Survey and Construction Program was distributed widely at Atlantic City, N. J., during the annual session of the American Medical Association in June. There has been good response to this pamphlet, and it is felt that considerable progress is being made. However, we still continue to need the very close cooperation of the state medical societies with the state advisory councils. Almost all the states have physicians on the advisory councils. It would be helpful, increasingly so as money becomes available and as state plans come up for discussion and approval, to remind the medical societies that they have an obligation and a stake in this program. There is no crisis, but there is need for a constant urging of attention. A good deal of public education is needed, not only of the patient public but also of the physician public. There are several things the U. S. Public Health Service is doing through the Federal Hospital Council, one of which is the establishment of an Office of Program Planning.
>
> Dr. F. S. Crockett, chairman of the Committee on Rural Medical Service, is a member of a special rural subcommittee of the Federal Hospital Council and, to fill a vacancy, Dr James E. Paullin, a member of this Joint Committee, is being asked to become a member of the Council.

Dr. Lull said he would include in his Secretary's Letter at an early date a statement such as that suggested by Miss Switzer and would recommend that the Council on Medical Service include a similar statement in its News Letter.

Dr. Sensenich said that one reason for slowness or lack of applications to participate in the program may be that some communities which have been accustomed to getting things done on their own without outside aid are far down on the priority list and thus have little or no interest; that obviously the areas which have first, second and third priorities are not organized, nor have they given much thought to the program, and that in such instances the state medical societies can be of considerable assistance. Miss Switzer agreed emphatically, saying that the state medical associations through their component county societies—community units most accustomed to working in an organized manner—could do a splendid job if they would. Dr. Mulholland stated that many areas which could get "A" priority do not have the finances to construct and maintain the facilities even with federal aid, and that some communities which have set aside money for the purpose still cannot do it because of present costs and are becoming discouraged. Miss Switzer agreed that costs probably were having a delaying effect on completion of the plans. Only a few state plans, she said, have been completed and approved.

STUDENT NURSE RECRUITMENT PROGRAM

The following communication from Mr. George Bugbee, executive director of the American Hospital Association, was read by the Chairman, who presumed that it contained the substance of what Mr. Graham Davis would have reported if he could have been present:

> I thought you would like to be brought up to date on the progress of the 1947 Student Nurse Recruitment Program which, as you know, is being conducted by the American Hospital Association and the Advertising Council, Inc., in cooperation with national nursing organizations and the American Red Cross. The program also has the endorsement and active support of such national organizations, in addition to the American Medical Association, as the American Medical Association Woman's Auxiliary, the U. S. Chamber of Commerce, Rotary International, Kiwanis, the National Tuberculosis Association and the American Public Health Association, to name a few.
>
> In addition to the initial contribution of $10,000 made by the American Hospital Association, the American Red Cross has also contributed $10,000 and more than $16,000 has been received as voluntary contributions from more than five hundred schools of nursing. These funds, for the most part, have been allocated to the Advertising Council for newspaper advertising mats, posters, car cards, billboard posters and other promotional material. A series of newsletters is being distributed, approximately weekly, to all schools of nursing and to local student nurse recruitment committees.
>
> An important part of the national backdrop of publicity has been the allocation of seven weeks of national radio network time on behalf of the program. The Advertising Council Radio Division estimates that during the first fifteen weeks of 1947 more than 527,295,000 listener-impressions have resulted. During the month of July 45,000 window display posters, 70,000 street car and bus posters and 2,000 billboard posters have been distributed by the Advertising Council throughout the country. This, together with a week of national radio network time (which began Monday, July 28) climaxed the national publicity program for the campaign.
>
> Preliminary surveys among the schools of nursing indicate that, in some areas, a marked degree of optimism prevails regarding the likelihood of obtaining desired fall class quotas. In other areas, however, the situation does not look too promising.
>
> The 1947 Student Nurse Recruitment Committee, of which Dr. Arestad is a member, expressed the opinion at its recent meeting that an effort should be made to secure additional and more active support from the American Medical Association and particularly from its local medical societies. In the last analysis the success of the program rests primarily with the initiation and active development of local student nurse recruitment programs. One of the main objectives of the committee has been to stimulate and assist the further development of such programs. As you well know, the members of the medical profession have a vital interest in seeing that the need for student nurses is filled. The shortage of professional nurses affects the physician in two ways: (1) lack of graduate nurses in hospitals has forced hospitals to close beds which are greatly in demand by physicians for their patients, and (2) physicians have been unable to obtain the number of professionally trained nurses desired for employment in their offices.
>
> Therefore, I would like to suggest that you consider the following as an important contribution the American Medical Association may make to 1947 Student Nurse Recruitment:
>
> 1. Through THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, continue to call the attention of your membership to the interest they have in assisting in obtaining the 45,000 student nurses needed this year.
> 2. Urge local medical society officers and members to fully investigate the situation locally, determine the various ways in which they may most effectively participate in local programs, and point out specific activities they may carry out which will directly aid the program. (These may take the form of distributing information and material to young women whom they believe are likely candidates for nursing school; active participation in recruitment programs; underwriting of scholarships for young women financially unable to pay for the costs of nursing education and who are otherwise qualified; conveying to the public whenever and wherever possible, the opportunities and advantages which a career in nursing offers.)

Dr. Hullerman, in attendance in place of Mr. Davis, spoke as follows:

> The Student Nurse Recruitment Committee has recommended that this recruitment be continued in 1948 on somewhat the same pattern, from an organizational standpoint, as obtained this year. The initial steps have been taken; also, the matter of necessary financing has been investigated. The 1947 program had much more substance than the 1946 one had. The Committee is rather hopeful that the enrolment this year is going to be large. Preliminary figures indicate that 80 to 85 per cent of the number of students desired have been obtained.
>
> The Recruitment Committee has expressed the opinion that the local physician can either set or alter the decision of a girl to enter nursing. In 1948, if the program continues to the extent that specific action can be taken so that the recruitment program can be brought to the attention of the physicians themselves, their influence would be most helpful.

In reply to a question as to what had been or is obstructing recruitment, Dr. Hullerman stated that many persons complain of unfavorable hours and, often, circumstances which they claim are inseparable from the profession of nursing, and there is prevalent a great deal of misinformation. However, he continued, the recent survey of the U. S. Department of Labor presents quite a favorable picture of the profession, and many hospitals are offering positions that are comparable with other positions available to women.

PRACTICAL NURSES

Father Schwitalla presented the following statement concerning the education, necessity for and supply of practical nurses:

> I felt at first that this was a rather minor matter, but when I went over some of the papers and books that have been published, I discovered that a great deal has been written, that there has been much discussion and that it concerns a large number of persons. The schools of nursing seem to be fearful as to what is happening, anticipating the disappearance of the so-called basic professional nurse who has her three years of training·

> they do not welcome a diffusion of professional attitudes, such as certainly would be the case if a great deal of the nursing were to be done by practical nurses. Another factor in the picture is that universities with a policy of issuing nursing certificates are preponderantly opposed to the issuance of anything lower than a degree. Hospitals in some localities are greatly concerned in the development of the practical nurse. Strange to say, those hospitals that seemed most in favor of the volunteer help during the war and shortly after seem now to be least in favor of the practical nurse. It seems to be the concensus of the hospitals that the practical nurse of today should be used to do the things which the Nurse's Aide did during the war. I find a growing lack of interest in the practical nurse today, even in those hospitals that had favorable experience with the volunteers. Some of this lack of interest may be due to a lack of understanding as to where the lines will be drawn. There are fifty schools for the training of practical nurses; only a very few require one year of high school education and only one requires two years.
>
> It seems to me that those who are guiding the future of nursing are inclined to regard the development of more practical nurses as something that is here to stay. I am most concerned as to what the fate of the patient will be if any appreciable number of practical nurses are used either in the hospitals or in private practice.

During the discussion Dr. Fischelis asked how many states license practical nurses and was informed that there is some reference to them in the laws of nineteen states and the territory of Hawaii. He thought that when the practical nurses see that they have some status in a state and can obtain licenses, they are likely to think they are as good as registered nurses. Miss Switzer noted that there is much variety in the requirements of the states and the schools, that Massachusetts has had a practical nurse-training program the graduates of which were substantial people in what they could do and the responsibilities they could take. Father Schwitalla said that the woman who heads the organization of practical nurses seems to have a definite conviction that unless we do have practical nurses we are not going to be able to provide a healthy American people, and that in one of her recent papers she stated that there is a place for this kind of woman in health care quite distinct from the place of the graduate nurse. He mentioned an interesting expression in a recent article to the effect that a graduate nurse should be looked on as an Army officer and the practical nurse as one of the rank and file, the implication being that we should have very many more practical nurses and few graduate nurses.

AMERICAN MEDICAL ASSOCIATION COMMITTEE TO STUDY NURSING PROBLEMS

The Chairman informed the Joint Committee that pursuant to action by the American Medical Association House of Delegates in June a Committee to Study Nursing Problems had been appointed by the President of the Association with Dr. Thomas P. Murdock of Connecticut as chairman, and that while the new committee has not yet had a meeting its members have been studying available material and literature. He read the following excerpts from a letter received from Dr. Murdock:

> As yet the Committee to Study Nursing Problems has not met due to vacations and previous commitments. So far we have reviewed all of the nursing journals having to do with this problem. We have the statements made by Dr. Frank Lahey and Dr. Naffziger. We have reviewed the report of the American Surgical Society and have reviewed all of the literature gathered by Dr. MacEachern from the American College of Surgeons. We have reviewed the study that was made for the nurses by the U. S. Department of Labor. We have had correspondence with many of the leaders of nursing in America. We have been in contact with Mr. Frederick Ayer of Boston, who seems to know a good deal about this situation as a layman. Dr. Frank Dickinson is working on retirement studies. We have purposely postponed meeting with the American Hospital Association group and the nursing groups until we are in better position to discuss this problem.
>
> It looks like an enormous job, and I think that probably we will only report progress at the meeting in Cleveland but that we will have a full report for the annual meeting in Chicago.

NAVY EDUCATIONAL PROGRAM

Captain Eaton informed the Joint Committee regarding the program of the Navy in medical education as follows:

> The Navy's program in medical education is now well established. Continual improvement is being made in the hospital provisions; libraries are being established and elaborated, and the eight specifically named hospitals to carry on a major portion of the program are now functioning. We are sending men into the civilian hospitals for training courses, some of which cover many months.
>
> The entrance of new officers into the Navy Medical Corps is not encouraging. The following memorandum has the approval of those in the Bureau of Medicine and Surgery who have to do with this program:
>
>> The legal office of the Surgeon General has been asked to consider and make recommendations concerning scholarships to medical students with the idea in mind of having a reliable and constant source of medical officers for the Medical Corps of the Navy. It is believed that if legislation is introduced it will apply in the case of the Armed Services generally and possibly the Public Health Service, although that will of course be a matter for the Congress to determine.
>>
>> It is considered that the granting of scholarships to worthy students would to a measure aid in alleviating the present shortage of physicians, not only in the Armed Services but also in civilian life. In addition, it would enable capable and ambitious young men, who otherwise could not do so because of lack of money, to pursue a medical education.
>>
>> Such a program would depend on the cooperation and support of civilian medical agencies and medical schools and it is desired to ascertain their reaction, not only to the desirability of the idea, but also as to the practical details involved. Should opportunity present itself, it is requested that you present the matter informally to the planning board of the American Medical Association or the Emergency Medical Service Committee of the American Medical Association.

Miss Switzer asked if it was implied that a man accepting the terms outlined committed himself to service for a certain length of time, and Captain Eaton answered in the affirmative. Miss Switzer said that one or two states are attempting to finance medical students in that way with the provision that they practice in the state for a stated period.

RURAL MEDICAL SERVICE

Dr. Mulholland presented the following information with respect to activities of the Committee on Rural Medical Service:

> The plans for the next National Conference on Rural Health to be held in Chicago in February 1948 are well under way. The main theme probably will be Rural Health and the Child. The Committee on Rural Medical Service is cooperating with the Council on Medical Service in connection with its regional meeting to be held in New Orleans this fall. The Committee feels that it is of great importance to stimulate members of local and state medical societies to consider the problems of rural medical service. It is sometimes difficult to get the state and local societies to do very much. It is planned that each regional chairman of our Committee will visit each state medical society meeting in his district and ask for support.
>
> Material is being sent to the various farm journals from the American Medical Association in the hope that those publications will print it. Representatives of our Committee met recently with the Women's Committee of the National Cooperative Milk Producers Federation and discussed ways and means of improving the health of persons in rural areas.

PROGRESS REPORT ON AMERICAN RED CROSS BLOOD PROGRAM

Dr. Draper offered the following statement concerning the Red Cross Blood Program:

> The program of the Red Cross for the collection of blood was approved by the House of Delegates of the American Medical Association at its annual session this year. The Board of Governors of the Red Cross approved the program at a recent meeting in Cleveland. Vice Admiral Ross T. McIntire, former Surgeon General of the U. S. Navy, has accepted the directorship of the program and is now engaged in organizing the work. It is hoped that by Christmas this year there will be at least one blood donor center set up in each of the five Red Cross areas. Many applications for the establishment of blood donor centers have been received, and these applications are given very careful consideration with respect to facilities offered.
>
> The principal features of the program are: (1) collection; (2) processing—breaking it down into its derivatives, packaging and storing; (3) distribution; (4) continuation of research; (5) maintenance of the highest standards in collection, processing and distribution, and (6) educational and promotional activities which are extremely necessary in getting persons to donate blood. The budget for the blood program has been set up, and several key persons have been employed. Admiral McIntire and I are determined that this program shall be conducted only with the hearty approval of the medical societies and health authorities in the areas where it is established.

COURSES IN MEDICAL ASPECTS OF ATOMIC ENERGY

General Armstrong asked how many medical schools have recognized the impact of public opinion to the extent that they have instituted courses in the medical aspects of the atom. Father Schwitalla said he knew of none in the undergraduate classes, and Dr. Mulholland stated that his school at Charlottesville, Va., had sent five of its medical students to Oak Ridge, Tenn., for study and observation. General Armstrong knew of two schools that have set up such courses and supposed that they are the graduate schools. It was his opinion that the military services are recognizing the importance of every medical officer knowing something about the subject, and he wondered how soon a similar recognition on the part of civilian physicians might be expected.

TIME AND PLACE OF NEXT MEETING

It was decided to hold the next meeting at American Medical Association Headquarters in Chicago on Saturday, Dec. 6, 1947.

GOVERNMENT SERVICES

ARMY

NEW CHIEF OF ARMY NURSES

The Surgeon General's Office announced October 1 the appointment of Col. Mary G. Phillips as chief of the Army Nurse Corps to succeed Col. Florence A. Blanchfield, who has retired after nearly thirty years of service. Colonel Phillips is a native of Wisconsin. She has been in the Army Nurse Corps since 1939 and during the recent war was deputy superintendent and later was director of nurses in the Pacific theater of operations.

NURSES AND DIETITIANS COMMISSIONED

The President tendered recess appointments in the Regular Army in October to one hundred and fifty-three officers and former officers of the Army Nurse Corps, thirty-one hospital dietitians, nineteen physical therapeutists and three occupational therapeutists, many of whom had served during World War II. These appointments are the first in the integration program resulting from the establishment by the last Congress of the Army Nurse Corps and the Women's Specialist Corps as part of the Regular Army. This is the first time that commissioned officer status has been given to occupational therapeutists. Among the nineteen physical therapeutists commissioned was Major Emma E. Vogel of Mankato, Minn., who has continuously served the medical department of the Army for twenty-eight years and who during World War II was director of physical therapeutists in the Surgeon General's Office.

DEPENDENTS OFFERED AIR TRAVEL TO PACIFIC AREA

A limited number of dependents of the Army and Air Force enlisted and officer personnel stationed in the Pacific area will be flown to their destinations in four-engine planes of the U. S. Air Transport Command, which will carry special equipment for the preparation of baby foods en route, since infants aged 6 months or over may now be flown. All dependents may be given the opportunity to indicate preference for air or surface travel. This arrangement, the War Department announced, has been made to avoid delay during the reconversion of many Army transport vessels for peacetime use.

ARMY AWARDS AND COMMENDATIONS

Lieut. Col. Philip S. Foisie

The Bronze Star Medal has been awarded to Lieut. Col. Philip S. Foisie (then Major), M. C., U. S. A., of Boston. The citation read as follows: For meritorious service in connection with military operations as Assistant Chief of Surgical Service, 7th General Hospital, from Dec. 20, 1943 to July 19, 1944. On two occasions Major Foisie was charged with establishing and opening hospital plants and placed in command of hospital detachments. Although inexperienced in the administrative and executive duties required, he demonstrated such qualities of adaptability, leadership, wisdom and devotion to duty that these missions were performed with complete success. The outstanding accomplishments of Major Foisie reflect great credit on himself and the armed forces of the United States. He was also awarded the Legion of Merit for outstanding service as chief, Surgical Service, 129th General Hospital in the ETO from July 20, 1944 to June 11, 1945. Dr. Foisie graduated from Harvard Medical School in 1924 and entered the military service June 19, 1943.

PERSONALS

Major Gen. Merritte W. Ireland, retired, formerly Surgeon General of the Army, has resigned as president of the Army Mutual Aid Association after eighteen years of service and as a director of that organization for thirty-two years. He has been succeeded on the board by the present Surgeon General, Major Gen. Raymond A. Bliss.

George W. Hervey, Ph.D., former chief administrative analyst for the director of plans of the Surgeon General's Office, has been named head of the statistical division of the American Red Cross National Blood Program and will establish methods for collecting and analyzing the data related to a program which will undertake, under the general direction of Ross T. McIntire, former Surgeon General of the Navy, to provide blood and blood derivatives without charge throughout the nation. Dr. Hervey is a veteran of both World Wars, having been released as a colonel in 1946. He is a graduate from Rutgers, receiving his M.A. degree from Missouri and his Ph.D. degree from Harvard.

NAVY

NAVY DAY

The twenty-sixth observance of Navy Day, October 27, was celebrated at all naval medical establishments. At the Medical Center, Bethesda, Md., there was an "open house" to the public, and staff members conducted visitors through the Center. The Surgeon General, Rear Admiral C. A. Swanson, was the principal speaker in the evening.

FLIGHT SURGEONS GRADUATE

On Sept. 12, 1947 eighteen naval medical officers received their designations as flight surgeons at the Naval Air Station, Pensacola, Fla., after having completed twelve weeks of classroom and laboratory work followed by seven weeks of flight training and ground school. The class convened on May 8, with thirty-three officer members. Fifteen were graduated as aviation medical examiners at the end of twelve weeks of instruction, while the remaining members continued in active flight training for seven more weeks. Capt. William Sinton, U. S. N., commanding officer of the Naval Air Station, gave the commencement address.

Capt. Bruce V. Leamer (MC) was relieved as officer in charge of the School of Aviation Medicine and Research by Capt. Wilbur E. Kellum (MC), Sept. 12, 1947. Other recent additions to the staff of the school are Comdr. Charles F. Gell (MC), as executive assistant to the officer in charge with additional teaching duties in physiology, and Lieut. Comdr. Philip B. Phillips (MC), as head of the Neuropsychiatry Department.

PERSONALS

Rear Admiral T. C. Anderson (MC), commandant, Naval Medical Center, Bethesda, Md., recently addressed the University of Michigan Medical School, Ann Arbor, at their annual convocation on "Progress of Medical Education."

Rear Admiral Lamont Pugh (MC), Assistant Chief, Bureau of Medicine and Surgery, was guest speaker at the first regular monthly meeting at the Naval Hospital, Philadelphia, October 24.

The Swedish government recently appointed Capt. Erik G. Hakansson (MC), U.S.N., commanding officer, Naval Medical Research Institute, Bethesda, Md., a Knight of the Royal Order of Vasa, first class, in recognition of his services during the tenth International Congress of Military Medicine and Pharmacy in 1939. The award was presented by Rear Admiral T. C. Anderson, commandant, National Naval Medical Center, Bethesda, Md.

Dr. Kronfeld to Give the Schoenberg Lecture.—The Mark J. Schoenberg Memorial Lectureship has been established in honor of Dr. Schoenberg's interest and original work in the control of glaucoma under the joint sponsorship of the New York Society for Clinical Ophthalmology, of which he was founder and president, and the National Society for the Prevention of Blindness, which he served as chairman of the committee on glaucoma. The first lecture will be held at the New York Academy of Medicine December 1 at 8 p. m., with Dr. Peter C. Kronfeld, Chicago, speaking on "The Canal of Schlemm." For many years Dr. Schoenberg was instructor in ophthalmology at Columbia University College of Physicians and Surgeons, and chief in the glaucoma clinic, Herman Knapp Memorial Hospital. He died Feb. 15, 1945.

OKLAHOMA

Hospital News.—A gift of $300,000 from the Price Foundation of Greenwich, Conn., to the Benedictine Sisters' charity hospital at Guthrie was announced at recent ceremonies attending the laying of the cornerstone.

Outing at Lake Murray.—The Carter County Medical Association, under the direction of Dr. James M. Gordon, Ardmore, president, met at Lake Murray early in October. After dinner Dr. George Garrison, professor of pediatrics, University of Oklahoma School of Medicine, Oklahoma City, spoke on diseases and nutrition of the newborn. A sight-seeing tour in motor boats along the hundred and thirty-five mile shore line of Lake Murray preceded the feast.

WISCONSIN

First Gundersen Lecture.—The first in a series of lectures, made possible through the generosity of the Gundersen Clinic in honor of the late Dr. Adolf Gundersen of LaCrosse, was given at the University of Wisconsin October 15. Dr. Erik Ask-Upmark spoke on "The Spleen and Some of Its Disorders." Dr. Gundersen was one of the pioneer physicians and surgeons in Wisconsin. He served the state university as one of its regents.

Form Rheumatism Association.—Physicians from various parts of the state met September 15 and formed the Wisconsin Rheumatism Association (1) to cooperate with the American Rheumatism Association, (2) to sponsor and assist in a state program for the prevention of rheumatism and for improved care and rehabilitation of patients with rheumatism, (3) to promote the education of physicians regarding the prevention and treatment of rheumatism, (4) to accumulate data on the rheumatic diseases and (5) to receive and expend money to foster the purposes of the association. Dr. Milton C. Borman, Milwaukee, was elected president, and Dr. Campbell C. Edmondson, Waukesha, secretary-treasurer.

GENERAL

Social Work Fellowships.—A limited number of $2,400 fellowships are available to experienced social workers who have a masters degree for advanced training in teaching and administrative responsibilities leading to a certificate for advanced psychiatric social work. The fellowships are offered by the University of Pittsburgh, the School of Social Work, in cooperation with the Veterans Administration Hospital at Topeka, Kan., and the Menninger Foundation Field Training Center for Psychiatric Social Work.

Shoes for Mismated Feet.—The Benefit Shoe Foundation, a nonprofit corporation offering single shoes and odd pairs at cost for amputees, paraplegics and others with mismated feet, began operation October 14 at the Bristol Manufacturing Corporation, Bristol, R. I. The foundation will not attempt to provide orthopedic or special shoes of any kind. It will simply make available regular standard make shoes singly or in mismated pairs. The foundation was started at the suggestion of the National Foundation for Infantile Paralysis.

Women Doctors Designate Blackwell Day.—The one-hundredth anniversary of the entrance of the first woman into medical school, November 7, has been designated as Blackwell Day by the Medical Women's Library Committee of the American Medical Women's Association, in honor of Dr. Elizabeth Blackwell, the first woman in the world to receive an M.D. degree. The association is raising a fund of $500,000 with which to erect a Medical Women's Library and Blackwell Memorial Hall on the campus of the Woman's Medical College, Philadelphia, which has given the site and vouched for the upkeep. The library is also seeking books written in any language by or about women in medicine, dentistry or science for the library (The Journal, July 19, p. 1035).

Southern Association to Meet in Baltimore.—The Southern Medical Association has accepted the invitation of the Baltimore City Medical Society to hold its annual meeting in Baltimore November 24-26. The entire scientific program will be presented by faculty members of the Johns Hopkins Medical School and the University of Maryland School of Medicine and College of Physicians and Surgeons, as well as by prominent members of the profession in Baltimore. A general public session will be held Monday evening. The twenty-one sections of the association will hold their meetings Tuesday and Wednesday.

Dr. Verhoeff Awarded Dana Medal.—The National Society for the Prevention of Blindness has awarded the Leslie Dana Medal this year to Dr. Frederick H. Verhoeff, Boston, for outstanding achievement in the prevention of blindness and the conservation of vision. The medal was presented during the faculty luncheon of the American Academy of Ophthalmology and Otolaryngology in Chicago, October 16. Dr. Verhoeff is professor of ophthalmic research emeritus at Harvard Medical School and consulting chief of ophthalmology, Massachusetts Eye and Ear Infirmary, Boston. He graduated from Johns Hopkins School of Medicine in 1899; he served as a major in the medical corps of the U. S. Army in 1918, as president of both the American Ophthalmological Society and the New England Ophthalmological Society and as chairman of the Section on Ophthalmology of the American Medical Association. Dr. Verhoeff was selected for the Dana Medal by the St. Louis Society for the Blind, through which it is offered by Mr. Leslie Dana, St. Louis, on recommendation of the Association for Research in Ophthalmology.

Research on Orthopedic Appliances.—A multiple research fellowship on orthopedic appliances has been established at the Mellon Institute, Pittsburgh, by the Sarah Mellon Scaife Foundation of Pittsburgh. Under the guidance of orthopedists and with the cooperation of leading organizations in the field and manufacturers of orthopedic appliances, the fellowship will accord particular attention to problems of mechanical design, improvements in materials of construction and methods of fitting braces and other orthopedic devices. John L. Young, Ph.D., a research specialist in metallurgy and mechanical engineering who has been active on the investigatory staff of Mellon Institute since 1928, heads the program as senior fellow and assistant director. Eugene F. Murphy, M.E., staff engineer, committee on artificial limbs, National Research Council, Washington, D.C., will serve as advisory fellow. Several research assistants will complete the initial personnel of the fellowship. The medical advisory committee of the fellowship is under the chairmanship of Dr. Paul B. Steele, professor of orthopedic surgery, University of Pittsburgh School of Medicine. Other members of the committee are Drs. John A. Heberling and Carl C. Yount.

International Cancer Research Commission.—At the Fourth International Cancer Research Congress, in St. Louis, September 2-7, an International Cancer Research Commission was established as an almost autonomous division of the Union Internationale Contre le Cancer by the thirty-nine nations represented. It is expected that the number of member nations soon will be increased. Each nation, regardless of size, has but one representative on the commission, and all representatives have equal voting power. Meetings are to be held annually, never consecutively in the same country. The following executive committee of the International Commission was elected, each member having an alternate to act for him if necessary: Ignacio Millan, Mexico, chairman, with F. Leborgne, Uruguay, alternate; Edmund V. Cowdry, United States, with William U. Gardner, United States, alternate; V. R. Khanolkar, India, with Tu-Shan Yung, China, alternate; J. H. Maisin, Belgium, with A. Lacassagne, France, alternate, and A. Haddow, England, with J. Engelbreth-Holm, Denmark, alternate. The purpose of this commission is to promote international cooperation in cancer research. This newly created International Cancer Research Commission does not in any way replace the much larger International Cancer Research Congress, which will continue to meet in different parts of the world at intervals of about three years.

Nobel Prize Winners in Medicine.—The 1947 Nobel Prize in physiology and medicine has been awarded to Dr. Carl F. Cori and his wife, Dr. Gerty Cori, of St. Louis, and Dr. Bernardo A. Houssay of Buenos Aires, Argentina. Half of the $48,580 cash prize will go to Dr. Houssay, and the Coris will share the other half. Dr. Cori and his wife were given the award for their discovery of the process in the catalytic metabolism [illegible] en. The enzyme phosphorylase, which they isolate[illegible] e c [illegible] al starch into sugar in the bod[illegible] ssa [illegible] his discovery of the significance of the hormone produced by the frontal lobe of the hypophysis and its importance in the distribution of glycogen in the body and in the control of diabetes. Dr. Cori is head of the biochemistry department and his wife is an associate professor of research in biological chemistry at Washington University School of Medicine, St. Louis, where they have been on the faculty since 1931. They graduated in medicine in Prague in 1920, came to this country in 1922 and became naturalized citizens in 1928. Dr. Houssay received his M.D. degree at the Colegio Britanico and Faculties of Pharmacy and Medicine, Buenos Aires, 1904. He was professor of physiology at the University of Buenos Aires, 1919 to 1943, and with the assistance of the Rockefeller Foundation organized the Instituto de Biologica y Medicina Experimental in 1944. He has been a frequent lecturer in the United States.

Prevalence of Poliomyelitis.—Reports of cases of poliomyelitis for the periods indicated have been received from the division of public health methods, U S Public Health Service:

* Last two columns show reported incidence since approximate seasonal low week (week ended between March 15 and 21).

† Figures changed by corrected reports.

Analysis of the Nursing Crisis.—The American Nurses' Association, 1790 Broadway, New York, has analyzed the underlying problems in the nursing crisis, pointing out that the demand for nurses has skyrocketed in the last few years and that several factors deter young women from joining the profession and discourage many already registered from continuing. Long hours, split shifts, lack of retirement provisions and minimum salary increases characterize the nurses' working conditions. Their responsibilities have increased, thus requiring higher standards of education and performance. The U. S. Department of Labor statistics for October 1946 gave the average salaries for nurses in all fields, with the majority providing their own living quarters, as $170 to $175 per month. The majority of nurses work forty-eight hours a week, and many work fifty-four or more hours. Twenty-six states, Hawaii and Puerto Rico have laws requiring licensure of all who nurse for hire. Without laws in all states the public is at the mercy of many unqualified persons. Increased demands for nursing service arise from increased public interest in health, the development of hospital plans, increased hospital construction and federal social legislation. The American Nurses' Association, in cooperation with state nurses' associations, has organized a counseling and placement service available without charge to nurses and employers to promote a more equitable distribution of nursing service. The association is cooperating with committees from other groups to assist in meeting the nursing problem.

LATIN AMERICA

Medical Election.—The Sociedate Médico-Cirúgica do Pará, Brazil, elected the following officers for 1947 to 1949: Drs. Luiz Araujo, president; Quaresma Gama, vice president, and Afonso Rodrigues Filho, secretary. Other officers are Drs. Orlando Bordalo, Oscar Miranda, Avertano Rocha, Otávio Lobo, Rosário Conte, Orion Loureiro and Raimundo Chaves.

Pan American Congress on Ophthalmology.—The Third Pan American Congress on Ophthalmology will meet at Havana, Jan. 4-10, 1948, to which the governments of all Pan American countries have been officially invited by the government of Cuba. Drs. Duke, Elder and Cass of England; Fuchs, Lindner, de Viena, Bailliart, Velter, Dollfus and Hartman of France and Verhagen and Thiel of Germany will be guests of honor. There will be an exhibit of amateur art by ophthalmologists, and space in the exhibit should be requested before November 15. Books, pamphlets and other publications of American ophthalmologists can be exhibited by request in the exhibits of ophthalmologic literature or distributed during the Congress. On the social program there will be a "Pan American evening" in which ladies and gentlemen will wear typical regional dress. Information may be obtained from Dr. Miguel A. Branly, General Secretary, Edificio Bacardi 70, Piso, Havana, Cuba.

FOREIGN

International Congress on Biology.—The first International Congress on Clinical Biology will be held in Paris, France, November 20-22 with Professor Polonovski as chairman and Professors Justin Besançon and Fleury as vice chairmen. The opening session will be devoted to reports on syphilis, anemias, new results of examination of the cerebrospinal fluid and new observations in gastric physiology and pathology. During the second day, reports will be presented on methods of determination of hemoglobin, blood proteins, hepatic insufficiency and the dosage of hormones. The final session will be on new methods of demonstration of Löffler's bacillus, exploration of cytohormones in sterility, diagnosis of bronchial tumors and the clinical importance of 17-ketosteroids.

Marriages

FRANK J. KROBOTH Jr. to Miss Teresa Musolino, both of Binghamton, N. Y., in Canandaigua, July 5.

JOHN F. MCCABE, Hartsdale, N. Y., to Miss Margaret Ellen Bradley of Glenside, Pa., June 24.

PHILLIP PENNINGTON, Bloomington, Ind., to Miss Barbara Boyer of Indianapolis, August 29.

ROBERT CHARLES HAILE to Miss Lucele Clare Brady, both of Washington, D. C., September 6.

ROBERT PAGE BOUDREAU, Syracuse, N. Y., to Miss Elizabeth Davis of Geneva, Ill., July 2.

THEODORE KATZ, Linden, N. J., to Miss Ilse Steinberger of New York, September 7.

FRANK L. KARP, Brooklyn, to Miss Thelma Rita Goldman of New York, October 12.

MEYER DEWITT SCHNALL to Miss Ruth Vivian Renick, both of New York, June 29.

JAMES J. SRAIL to Miss Bernice Belden, both of Moline, Ill., August 3.

RALPH J. KAHANA to Dr. Eda Malisoff, both of New York, July 28.

Deaths

Ewen Murchison MacEwen ⊕ Iowa City; born in Greenwich, Prince Edward Island, Canada, Sept. 16, 1885; State University of Iowa College of Medicine, Iowa City, 1912; dean and professor of anatomy at his alma mater, where he joined the faculty as an instructor in anatomy in 1914, later serving as assistant and associate professor of anatomy and head of the department; president of the Association of American Medical Colleges in 1943, and in 1944 chairman of the executive council; member of the American Association for the Advancement of Science, American Association of Physical Anthropologists and the American Association of Anatomists; served as consultant for the Veterans Hospital; president of the First Federal Loan and Investment Company and vice president of the Iowa State Bank and Trust Company; died in the University Hospital September 2, aged 61, of coronary occlusion.

Charles Porter Small ⊕ Chicago; born in Bangor, Maine, Nov. 16, 1863; Medical School of Maine, Portland, 1889; an Affiliate Fellow of the American Medical Association; past president of the Chicago Ophthalmological Society; formerly physician to the University of Chicago, instructor in ophthalmology at the Chicago Policlinic and clinical associate in the eye department at Rush Medical College; served as a captain in charge of the aviation examination unit, Central Department of the U. S. Army during World War I; secretary and director of the Ophthalmic Publishing Company; at one time contributor to the American Encyclopedia of Ophthalmology and others; died in Princeton, Ill., September 25, aged 83, of hypertensive heart disease.

Vaclav Horace Podstata ⊕ San Francisco; born April 24, 1870; Chicago Homeopathic Medical College, 1895; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1900; associate clinical professor of psychiatry, emeritus, at the University of California Medical School; specialist certified by the American Board of Psychiatry and Neurology, Inc.; member of the American Psychiatric Association; formerly physician in charge of Oakwoods Sanitarium in Lake Geneva, Wis., superintendent of the Elgin (Ill.) State Hospital and physician in charge of the Livermore (Calif.) Sanitarium; for many years psychiatrist for the child welfare department of the schools of Berkeley; died August 15, aged 67, of pneumonia.

William Neer, Paterson, N. J.; born in Paterson, Aug. 22, 1866; College of Physicians and Surgeons, medical department of Columbia College, New York, 1891; fellow of the American College of Surgeons; formerly health officer; examiner for the draft board during World War I; part-time medical officer for the Wright Aeronautical Corporation during World War II; past president of the Passaic County Medical Society; for many years on the staff of St. Joseph's Hospital; died in Point Pleasant Hospital in Point Pleasant August 7, aged 81, of uremia, following fracture of the neck of the femur received in a fall from a bicycle.

Stephen L. Walczak ⊕ Buffalo; born in Buffalo, Nov. 30, 1897; University of Buffalo School of Medicine, 1921; specialist certified by the American Board of Surgery; fellow of the American College of Surgeons; associate in surgery at his alma mater, 1942-1943; formerly member of the city board of health; served during World War I; chairman of the Selective Service Board of Appeals number 23 during World War II; consulting surgeon, J. N. Adam Memorial Hospital, Perrysburg; affiliated with the Millard Fillmore, Mercy and Edward J. Meyer Memorial hospitals; died August 11, aged 49, of coronary heart disease.

William Albert Taylor ⊕ Ellensburg, Wash.; born in Toronto, Canada, Nov. 21, 1881; University of Toronto Faculty of Medicine, Toronto, 1907; specialist certified by the American Board of Surgery; member of the Western Surgical Association, Pacific Coast Surgical Association, North Pacific Surgical Association and the American Association for the Surgery of Trauma; fellow of the American College of Surgeons; affiliated with the Ellensburg General Hospital; surgeon for the Chicago, Milwaukee and St. Paul Railway and the Pacific Railway; died in Boston June 17, aged 65, of cerebral hemorrhage.

Lindley Dobson, Presque Isle, Maine; born in 1864; Bellevue Hospital Medical College, New York, 1891; member of the founders group of the American Board of Surgery; fellow of the American College of Surgeons; member of the American Medical Association and the New England Surgical Society; in 1941 received a "fifty year" medal of the type presented to members who have practiced for half a century by the Maine Medical Association; affiliated with the Presque Isle General Hospital; died July 4, aged 82, of carcinoma of the pancreas.

Mark Heiman ⊕ Syracuse, N. Y.; Syracuse University College of Medicine, 1897; formerly demonstrator of anatomy at his alma mater; member of the American Academy of Dermatology and Syphilology, of which he had been president; past president of the Syracuse Academy of Medicine; past chairman of the section on dermatology and syphilology of the Medical Society of the State of New York; on the staffs of St. Joseph Hospital and St. Mary's Maternity Hospital and Infants Asylum; died July 2, aged 71, of hypertensive heart disease.

Joseph Richard Adams, El Dorado, Kan.; University of Louisville (Ky.) Medical Department, 1901; served during World War I; died in Wichita July 21, aged 66.

John T. Anglin, Dover, Okla.; University of the South Medical Department, Sewanee, Tenn., 1900; served as president of the Kingfisher County Medical Society; died in the General Hospital, Enid, July 4, aged 70, of arteriosclerosis.

Harriet D. Covert Battles, St. Petersburg, Fla.; Toledo Medical College, 1900; died May 4, aged 87, of acute dilatation of the heart.

Charles Franklin Kingsbury Bean ⊕ Medford, Mass.; Harvard Medical School, Boston, 1912; past president of the Medford Medical Society and the Rotary Club; for many years affiliated with Lawrence Memorial Hospital; died July 23, aged 61, of hypertensive heart disease.

Norbert George Benesh, Minneapolis; University of Nebraska College of Medicine, Omaha, 1931; member of the American Medical Association; on the staff of the Lutheran Deaconess Home and Hospital; died June 28, aged 39, of coronary disease.

Harry Applebee Cheney, Campton, N. H.; University of Vermont College of Medicine, Burlington, 1894; member of the American Medical Association; served on the staff of the Sceva Speare Memorial Hospital, where he died July 15, aged 76, of carcinoma of the prostate.

Cyrus Eben Coffee ⊕ St. Louis; St. Louis University School of Medicine, 1911; affiliated with the Christian Hospital; died in the Barnes Hospital August 9, aged 69, of coronary thrombosis.

Victor C. Eddy ⊕ Colby, Kan.; the Hahnemann Medical College and Hospital, Chicago, 1884; served as county health officer; on the staff of St. Thomas Hospital, where he died August 9, aged 85, of pneumonia.

Robert Donald Ferguson ⊕ Ocala, Fla.; Tulane University of Louisiana School of Medicine, New Orleans, 1915; formerly vice president of the Florida Medical Association and member of the committee on venereal disease control; served overseas during World War I; died in the Municipal Hospital, Tampa, July 26, aged 55, of hypertensive heart disease.

Ben Bigelow Fisher, Wild Rose, Wis.; Wisconsin College of Physicians and Surgeons, Milwaukee, 1898; died June 11, aged 77, of cerebral thrombosis and hypertension.

Hugh Vincent Foley, Troy, N. Y.; Albany (N. Y.) Medical College, 1913; member of the American Medical Association; past president of the Rensselaer County Medical Society; died July 16, aged 59, of arteriosclerotic heart disease and nephritis.

Victor Ethel Fox, Tomnolen, Miss.; Memphis (Tenn.) Hospital Medical College, 1913; died August 12, aged 60, of heart disease.

Ephraim D. Friedrichs ⊕ New Orleans; Medical Department of Tulane University of Louisiana, New Orleans, 1900; died June 10, aged 70, of pneumonia following a fractured hip received in an accident.

Max M. Gara, New York Mills, N. Y.; Medizinische Fakultät der Universität, Wien, Austria, 1920; died June 30, aged 55, of coronary infarction and hypertension.

Harry Goldberg, Baltimore; Maryland Medical College, Baltimore, 1907; died June 23, aged 62, of brain tumor.

John Clifford Hancock ⊕ Dubuque, Iowa; Harvard Medical School, Boston, 1898; fellow of the American College of Surgeons; on the staffs of Finley and St. Joseph Mercy hospitals; died June 18, aged 75, of chronic myocarditis.

Benjamin George Haumesser, St. Louis; St. Louis University School of Medicine, 1919; died July 26, aged 53, of cirrhosis of the liver.

John Paul Keating ⊕ Philadelphia; University of Pennsylvania School of Medicine, Philadelphia, 1927; served during World War I; member of the staffs of Fitzgerald-Mercy Hospital in Darby and Misericordia Hospital; died July 17, aged 50, of acute coronary thrombosis.

Adam J. Knapp, Evansville, Ind.; University of Tennessee Medical Department, Nashville, 1893; died July 9, aged 93, of cerebral hemorrhage.

George Koeppel, Milwaukee; Illinois Medical College, Chicago, 1899; retired public school principal; died July 31, aged 87, of myocardial degeneration.

Harry Marcus Loewenstein ⊕ St. Louis; Washington University School of Medicine, St. Louis, 1902; for many years on the staff of the Missouri Baptist Hospital, where he died August 6, aged 69, of multiple sclerosis.

Lorenzo Peyton McCuistion ⊕ Paris, Texas; Kentucky School of Medicine, Louisville, 1889; fellow of the American College of Surgeons; selected as the 1931 recipient of a certificate of distinction awarded annually by the Winfield F. Brown post of the American Legion at Paris to a distinguished citizen of the town; physician in charge of the Sanitarium of Paris, where he died July 16, aged 77, of cardiac failure and myasthenia gravis.

Earle McCormick McLean ⊕ Bradford, Pa.; Jefferson Medical College of Philadelphia, 1904; past president of the McKean County Medical Society; served during World War I; on the staff of the Bradford Hospital, where he died August 3, aged 66, of sarcoma.

Angeline Martine ⊕ La Jolla, Calif.; Woman's Medical College of Pennsylvania, Philadelphia, 1892; at one time practiced in Utica, N. Y., where she was a member of the board of education and on the staff of St. Luke's Hospital; on the staff of Scripps Memorial Hospital, where she died July 17, aged 80, of cerebral hemorrhage.

Robert J. Nelson, Robersonville, N. C.; Louisville (Ky.) Medical College, 1890; member of the American Medical Association; died July 24, aged 83, of arteriosclerosis and cerebral hemorrhage.

David Joseph O'Connor, Croghan, N. Y.; University of Toronto Faculty of Medicine, Toronto, Canada, 1930; member of the American Medical Association; health officer since 1938; died July 15, aged 41, of an injury to the head received in a fall down the stairs.

John Panos ⊕ Dayton, Ohio; Eclectic Medical College, Cincinnati, 1925; died recently, aged 54.

Jesse Henley Phillips, Montezuma, Iowa; the Hahnemann Medical College and Hospital, Chicago, 1897; member of the American Medical Association; died July 30, aged 96, of senility.

Walter Ashby Plecker, Richmond, Va.; University of Maryland School of Medicine, 1885; member of the American Medical Association; joined the bureau of vital statistics of the state department of health in 1912, serving as director until he resigned in 1946; died in the Hospital Division of the Medical College of Virginia August 2, aged 86, of injuries received when he was struck by an automobile while crossing the street.

George Louis Preston, Canisteo, N. Y.; Eclectic Medical College of the City of New York, 1882; for many years health officer, county coroner and school physician; on the staff of Bethesda Hospital in Hornell; died August 2, aged 86, of acute dilatation of the heart.

Elum M. Russell, Salida, Colo.; Chattanooga (Tenn.) Medical College, 1899; at one time a resident of Gunnison, where he served as physician at Western State College; died August 7, aged 75, of myocarditis.

William Stephen Schuler, Chicago; Jenner Medical College, Chicago, 1905; member of the American Medical Association; on the staff of the Swedish Covenant Hospital; died August 24, aged 74, of cerebral hemorrhage.

Lloyd S. Settle, Mount Washington, Ky.; University of Louisville (Ky.) Medical Department, 1895; died August 11, aged 87, of uremia.

Guy Otey Shirey, Williams, Ariz.; University of Tennessee College of Medicine, Memphis, 1914; served during World War I; accompanied Admiral Richard E. Byrd to the South Pole on the second Antarctic Expedition; formerly district surgeon for the Southern Pacific Railroad, serving on the staff of Southern Pacific Hospital in Tucson; died in Fort Whipple June 30, aged 56, of cirrhosis of the liver.

Vladimir Nicholas Sikorsky, North Grafton, Mass. (licensed in New Hampshire in 1897); member of the American Medical Association and the New Hampshire Medical Society; died in St. Vincent's Hospital, Worcester, August 1, aged 80, of arteriosclerotic heart disease.

William Ebert Simon ⊕ Alva, Okla.; University of Kansas School of Medicine, Kansas City, 1913; served during World War I; died in the Alva General Hospital July 19, aged 60.

Jefferson B. Simons, Buckhannon, W. Va; Eclectic Medical Institute, Cincinnati, 1899; died July 25, aged 73, of heart disease.

Alexander Lorne Smith, Jersey City, N. J.; Queens University Faculty of Medicine, Kingston, Ontario, Canada, 1902; served in France as a captain in the medical corps of the U. S. Army during World War I; died July 1, aged 68, of cerebral thrombosis.

James Frederick Stafford, Lovilia, Iowa; Jefferson Medical College of Philadelphia, 1906; member of the American Medical Association; died July 5, aged 66, of coronary thrombosis.

Eugene W. Stevens, Onalaska, Wash.; Marion-Sims College of Medicine, St. Louis, 1893; member of the American Medical Association; served on the staff of St. Helen's Hospital in Chehalis; died in Chehalis June 27, aged 76, of carcinoma.

Joseph Alfred Stoner, York, Pa.; University of the City of New York Medical Department, 1886; died June 28, aged 85, of osteoarthritis of the lumbar spine.

Edward Francis Sullivan ⊕ Staunton, Ill.; St. Louis University School of Medicine, 1924; died August 1, aged 51, of coronary thrombosis.

Hugh H. Tabor, Weir, Miss.; Mississippi Medical College, Meridian, 1910; died June 10, aged 66, of heart disease.

William Francis Traughber, Lancaster, Calif.; College of Physicians and Surgeons, Los Angeles, 1911; died in July, aged 72, of cerebral hemorrhage.

Irving Emanuel Uram, Philadelphia; Jefferson Medical College of Philadelphia, 1942; member of the American Medical Association; interned at the Jefferson Medical College Hospital and served a residency at Philadelphia General Hospital; found dead near Thornhurst August 13, aged 30, following an airplane crash.

Algernon Stubblefield Vaiden, Monterey, Va.; University of Virginia Department of Medicine, Charlottesville, 1910; died August 1, aged 60, of heart disease.

Frederick Eugene Vest ⊕ Topeka, Kan.; State University of Iowa College of Medicine, Iowa City, 1885; Jefferson Medical College of Philadelphia, 1887; on the staff of Stormont Hospital; died in Kansas City, Kan., August 4, aged 88, of congestive heart failure.

Wilson Davenport Webb ⊕ Hackensack, N. J.; University of Buffalo School of Medicine, 1913; fellow of the American College of Surgeons; affiliated with the Hackensack Hospital; died August 6, aged 58, of cerebral hemorrhage.

Robert W. White, Youngstown, Ohio; Western Reserve University Medical Department, Cleveland, 1897; died July 23, aged 82, of coronary thrombosis.

Joseph Herbert Willis ⊕ Evansville, Ind.; Hospital College of Medicine, Louisville, Ky., 1897; fellow of the American College of Surgeons; on the staffs of the Deaconess and St. Mary's hospitals; died August 6, aged 75, of heart disease.

Arthur Lee Wilson, Lynchburg, Va.; Bellevue Hospital Medical College, New York, 1898; member of the American Medical Association; served during World War I; formerly president of the board of health and member of the city council; died August 4, aged 72, of cerebral hemorrhage.

Edwin Barnes Wilson ⊕ Brooklyn; Albany Medical College, 1905; for many years on the staffs of the Coney Island, Caledonian and St. Mary's hospitals; died August 3, aged 69, of cerebral hemorrhage.

John Thomas Winn, Cullman, Ala.; University of Tennessee Medical Department, Nashville, 1893; died in the Cullman Hospital August 4, aged 81, of chronic endocarditis with cardiac hypertrophy.

John Magee Wise ⊕ Watertown, Mass.; University of Buffalo School of Medicine, 1907; at one time superintendent of the New Hampshire State Sanatorium in Glencliff and the Sassaquin Sanatorium in New Bedford; formerly affiliated with the Middlesex County Sanatorium in Waltham; died August 7, aged 71, of coronary heart disease.

Sept. 27, 1947.

Congress of the International Society of Surgery

The twelfth congress of the International Society of Surgery was held in London, with the president, Dr. Leopold Mayer, of Brussels, Belgium, presiding. About one hundred members, including seventy official delegates from national committees of more than forty countries attended. The congress of the society had been held only once previously in London, in 1923. The president delivered an address, partly in French, partly in English, in which he recalled some of the famous members of the society: Emil Theodor Kocher would always be associated with the treatment of goiter; Czerny, of Heidelberg, Germany, would ever be famous for his researches on cancer, and Lucas-Championnière, of Paris, France, was immortalized by his work on orthopedic surgery. His own master, Antoine Depage, of Brussels, Belgium, showed organizing powers and military foresight equalled only by his surgical skill. The treatises of William Keen of Philadelphia on surgical technic are still [illegible]rred to. Others mentioned were Macewen, of Glasgow, [illegible]land; Giordano, of Venice, Italy; Hartmann, of Paris, and [illegible]s, of New Orleans. It was fitting that the country so valiantly led by Churchill should witness the first postwar international congress of surgery.

I. Penicillin in Surgery

At the first scientific session Sir Alexander Fleming discussed penicillin in surgery. He largely repeated what he said at the International Conference of Physicians. As the drug does not affect all microbes, the infecting organism must be susceptible to it. The dose must be adequate. There is now a tendency to higher dosage since correction of the original scarcity of penicillin. The drug must be administered so that it reaches the organisms. Intermittent injection is customary and there is evidence that it is not necessary to maintain a constantly high bacteriostatic level of the antibiotic in the blood. Ten minutes after injection a maximum concentration in the blood occurs; advantage can be taken of this in prophylactic use in extraction of septic teeth in rheumatic fever. Duration of treatment is important. While gonorrhea can be cured by one dose, subacute endocarditis may require treatment for months. Local treatment has definite possibilities. Pure penicillin can be injected into the theca in high concentrations without local irritation. Subconjunctival injections give hi[illegible] ncentrations in the eye.

Professor Walters, of the Mayo Clinic, said [illegible] ore the advent of penicillin staphylococcic septicemia car[illegible] ality of over 90 per cent in patients over 40 years o[illegible] on-amide drugs reduced the mortality to 40 per [illegible] ith penicillin it is well under 20 per cent. The effecti[illegible] drug in pyogenic meningitis and abscess of [illegible] remarkable. In thoracic surgery 50,000 units in isotonic sodium chloride solution have proved of imm[illegible] against empyem[illegible] In postoperative pneumonias it [illegible] outstandingly e[illegible]

II. Vascular S[illegible]

An ovation was g[illegible] Blalock, Johns H[illegible] Hospital, for the pr[illegible] operation for cong[illegible] pulmonary stenosis. U[illegible] ory treatment for [illegible] form of congenital heart [illegible] Since then a[illegible] advance has been made in [illegible] oups, patent ductus arteriosus, coarctation [illegible] sis. The object of his operation was to [illegible] vessel of the general circulation with high pressure to one of the pulmonary arteries with low pressure. On the right side the innominate, carotid or subclavian artery and on the left, the subclavian artery or possibly the aorta could be used. The object was to connect the systemic and pulmonary circulations. He usually performed end to side and occasionally an end to end anastomosis. Dr. Blalock showed a motion picture of the entire operation, ligation of the azygos vein, division of the mediastinal pleura, exposure of the right pulmonary artery, exposure of the innominate artery under the superior vena cava and anastomosis between the end of the subclavian artery and the side of the pulmonary artery. A fortnight after operation cyanosis had usually disappeared. Disappearance of clubbing of the fingers usually occurred later. In 474 cases there had been 86 deaths, but 18 fatalities followed operations in which it had been impossible to find a pulmonary artery. Among the last 38 successive cases there had been no deaths. Most of the patients who survived the operation had improved. Some who could walk only a few steps before now could walk miles. He showed 2 patients, a girl aged 3 and a boy aged 9, who had recently undergone this operation. They appeared to be normal children.

III. Social Functions

The president and council of the Royal College of Surgeons entertained representatives of most of the nations taking part in the congress at dinner. Professor G. Grey Turner led delegates and members on a pilgrimage of homage to places in London associated with John Hunter and Joseph Lister. Hunter's famous house in Leicester Square was visited first, then the church of St. Martin's in the Fields, where Hunter was originally buried. After sixty years his remains were removed at the expense of the Royal College of Surgeons to Westminster Abbey. The Abbey and the College, which has the marble statue of Hunter by Henry Weekes, were visited. Here the portrait of Lister by Ouless was displayed, as well as various pictures and instruments having an association with Hunter.

Lister's house and his statue in Portland Place were also visited and lastly University College, where exactly one hundred years ago Lister received his bachelor of arts degree.

IV. American Surgeons Honored; Gift to the Royal College of Surgeons

At a special ceremony five American surgeons were made honorary fellows of the Royal College of Surgeons, one was presented with the [illegible] ry Medal of the College and another with the Lister Me[illegible]

Sir Alfred Webb-[illegible] the president, said that the records of those it was pr[illegible] honor were a reminder of many great achievements [illegible] d States and Canada. The first recipient of the hon[illegible] ship was Dr. Arthur W. Allen, president of the A[illegible] ollege of Sur[illegible] He was introduced by Sir [illegible] lvie, who sa[illegible] Dr. Allen had made contributi[illegible] importance [illegible] ic surgery. Dr. Irvin Abell, of [illegible] t president [illegible] American College of Surgeons [illegible] oward La[illegible] Dallas B. [illegible] hemister, presiden[illegible] r. Alfred [illegible] were the [illegible] recipients. [illegible] Medal o[illegible] was [illegible] ed to Dr. W[illegible] past pre[illegible] Ameri- [illegible] of Su[illegible] Evarts [illegible]

(From Our Regular Correspondent)

Florence, Aug. 30, 1947.

Association for the Study of Allergy

The first scientific meeting of the Italian Association for the Study of Allergy was held in Milan Professor Amilcare Zironi was chairman and Professor Sangiorgi, whose initiative and activity was instrumental in the establishment of the association, acted as secretary. Professor Zironi announced that the invitation to join the International Association for Allergists had been officially accepted

Professor Guido Melli reported on antihistaminic compounds in the treatment of allergic diseases; he reported the results obtained with nicotinamide and with two recent antihistaminic compounds, "antergan" (dimethylamino-ethyl-benzylamine) and "antistin" (2-(N-phenyl-N-benzyl-aminomethyl)-imidazolin. The definitely different therapeutic behavior and the different degree of biologic activity are responsible for the statement that nicotinamide works by another mechanism, although it possesses an antihistaminic activity. The speaker did not obtain immediate results with nicotinamide, but a protracted course of treatment yielded relatively favorable, permanent results in bronchial asthma and serum disease, both prophylactically and therapeutically. The results were doubtful in hemicrania. The treatment was practically ineffective in urticaria and in exudative eczema.

The results with the two other compounds experimented with were on the contrary obtained rapidly but were often only transitory. Good results were obtained in pruritus, in urticaria, sometimes in hemicrania and in exudative eczema. Results were negative in bronchial asthma, in serum disease, in 2 cases of acute articular rheumatism and in 1 case of erythema nodosum. The speaker considered it peculiar that bronchial asthma, the most typical allergic disease, proved completely refractory to this method of treatment and that favorable results were likewise obtained only occasionally by other authors. Professor Melli stated that this behavior may be explained by the fact that allergy may not be considered as a pathogenic factor in all cases of asthma.

Professor Piero Redaelli reported on morphologic manifestations of gastric allergy in describing 1 case of lead poisoning with nephritis and severe hypertension in a man aged 53; death resulted from cerebral hemorrhage. Necropsy revealed that the gastric mucosa, at the level of the pyloric antrum toward the lesser curvature, presented three elevated patches, each with a diameter of 1 cm., while the corresponding mucosa was curved like a watchglass and was pale. Microscopic examination revealed a circumscribed serous imbibition of the mucosa corresponding with a small inflammatory infection of the submucosa manifested by some polymorphonuclears and by monocytic elements which were accumulated in small congested blood vessels. Professor Redaelli emphasized that this change is something more important than a simple elevated patch; it may be interpreted as equivalent to a local anaphylactic process of Arthus' type, analogous to the well known manifestations of gastric allergy, such as urticaria, or Quincke's edema, which many times has been demonstrated clinically but very seldom pathologically.

Dr. Mario Staffieri stated that many times he has been able to observe factors of specific allergic sensibilization in patients who presented acute catarrhal manifestations of the middle ear. In 1 patient an endotympanic transudate and signs of auricular pain arose unexpectedly after the allergogenic *stimulus* of some intensely positive cutaneous tests. Also, in some cases in which the diagnosis of chronic catarrhal otitis media was made the auricular lesions were due to the acute endotympanic hydrops which, following the allergic stimuli, may recur and become chronic with the ensuing organization of the transudate. Other aspects of disturbances of the middle ear may be attributed to an allergic mechanism by interpreting them as complications of an allergy of the upper portion of the respiratory tract and sometimes as a manifestation of an allergic-hyperergic reaction localized in the middle ear. In those cases one has to deal with endotympanic transudates following an allergy to food or to inhaled agents; or tubal stenoses, depending on nasopharyngeal allergies; or tubal otorrhea in infants with exudative diathesis, with alimentary intolerance or with intestinal parasites depending on an allergizing action.

The papers presented at this meeting and those which will be presented at coming meetings will be published in the *Quaderni della allergia,* which will soon resume publication as the official bulletin of the Italian Association for the Study of Allergy.

Sept. 15, 1947.

International Union Against Tuberculosis

The Council of the International Union Against Tuberculosis, whose secretary general is Professor Fernand Bezancon, met in Paris on July 28-29, with Professor Lopo de Carvalho in the chair. Twenty-five nations were represented at this meeting: Austria, Belgium, Canada, Cuba, Czechoslovakia, Denmark, Finland, France, Great Britain, Greece, Hungary, India, Ireland, Italy, Luxemburg, the Netherlands, New Zealand, Norway, Poland, Portugal, Sweden, Switzerland, the United States, Uruguary and Yugoslavia.

Delegates from the United States included Dr. Kendall Emerson, Dr. Corwin Hinshaw, Dr. Herman E. Hilleboe, Dr. Esmond Long and Mr. F. D. Hopkins; from France, Professor Fernand Bezancon, Professor Etienne Bernard, Dr. Guerin, Dr. Rist and Dr. Poix (representing Dr. Bariety); from Great Britain, Drs. A. Morland, F. R. C. Heaf, Lloyd Rusby, R. R. Trail and Harley Williams.

The council decided that the closest cooperation is to be kept up with the World Health Organization; that the proposed modifications of the by-laws of the Union be examined and discussed. The constitution of the executive committee is to be altered, so that it should include, as well as existing members, delegates from South America, Canada, Denmark, India, Norway and Soviet Union.

The first scientific session, at the Laënnec Hospital, was devoted to the report by Professor Etienne Bernard on streptomycin. From a wholly objective point of view and with the help of excellent pictures, the speaker described the cures he had obtained and the negative results he had observed. This report was followed by a discussion in which the following members took part: Dr. Mollaret, Dr. Derscheid, Dr. Andre, Professor Omodei Zorini, Professor V. Fici and Dr. Yevrem Nedelkowitch.

During the second scientific session, at the great amphitheater of the Pasteur Institute, under the presidency of Professor Trefouel, director of the Pasteur Institute, Dr. Corwin Hinshaw described the research which he and Dr. Feldman accomplished on streptomycin, the clinical results they obtained, the hopes which could be entertained and the precautions which should be taken. The next conference of the Union is to be summoned in Copenhagen, Denmark, in 1950.

Correspondence

DOCTORS DISTINGUISHED AS SCIENTISTS

To the Editor:—Many doctors have done such excellent scientific research that they have been widely recognized as distinguished scientists. William James became America's most distinguished psychologist, David Starr Jordan one of the greatest zoologists, Samuel W. Williston an outstanding paleontologist, Asa Gray the most distinguished botanist of his period, Hrdlička one of the great anthropologists.

Among scientists sketched in the biographic directory, "American Men of Science," seven editions, 1906-1944, are some three hundred and fifty M.D.s starred as especially distinguished in research by secret vote of their fellow scientists.

Six anatomists had their undergraduate training at Harvard, 6 at Toronto, 5 at Michigan, 4 at Hopkins, 4 at Yale, 3 at Pennsylvania, and 2 each at Brown, Chicago, Cornell, Kansas, Missouri, Princeton and Washington (St. Louis). Teachers listed as especially stimulating by the anatomists who filled out the 1946 questionnaire were S. H. Gage (Cornell), F. P. Mall (Hopkins), C. M. Jackson (Harvard) and J. B. MacCallum (Hopkins).

Twenty pathologists had their undergraduate training at **Harvard,** 14 at Yale, 6 at Hopkins, 5 at Princeton, 4 at Michigan and 3 each at Amherst, Columbia, Massachusetts Institute of Technology and Toronto. Teachers reported as especially stimulating were W. H. Welch, W. H. Howell, *J. B. MacCallum* and William Osler (all at Hopkins).

Of the physiologists, Harvard gave college degrees to 12, Hopkins and Yale to 7, Chicago and Michigan to 6, Columbia and Wisconsin to 4, Illinois, Kansas and Pennsylvania to 3. *Physiology teachers listed as especially stimulating were* A. J. Carlson (Chicago), W. B. Cannon (Harvard), Jacques Loeb (Columbia), L. B. Mendel (Yale) and J. J. Abel (Hopkins).

Doctoral Training

Anatomists.—Hopkins conferred doctorates on 17 of the subsequently starred anatomists, Harvard on 9, Columbia on 7, Chicago and Michigan on 6, Brown, Pennsylvania and Yale on 3. Notably prominent in the graduate training of anatomists were F. P. Mall (Hopkins), R. R. Bensley (Chicago) and C. S. Minot (Harvard).

Pathologists.—Harvard with 30, Hopkins with 31, Columbia with 23 and Pennsylvania with 17 were the leading universities in the doctoral training of pathologists. No other school graduated more than 5. Graduating 4 or 5 were Bellevue, Chicago, Maryland, Michigan, Rush, Yale and McGill. Relatively important teachers in the doctoral training of pathologists were W. H. Welch, W. S. Halsted, W. H. Howell, W. G. MacCallum and William Osler (all at Hopkins) and G. H. Parker at Harvard.

Physiologists.—In the doctoral training of physiologists the early leader was Hopkins, by a wide margin; for those starred 1909-1943, Chicago led, with Harvard close behind. The totals for all periods were Hopkins 23, Chicago 14, Columbia 10, Harvard 10, Pennsylvania 8, Yale 7 and Michigan 6. Persons that were apparently relatively significant in the graduate training of physiologists were A. J. Carlson (Chicago), W. B. Cannon (Harvard), B. H. Chittenden and L. B. Mendel (Yale), J. Loeb (Columbia), J. J. Abel, F. P. Mall and *E. V. McCollum* (Hopkins) and G. Lusk (Cornell).

Birthplaces

Anatomists.—Of the 11 foreign-born starred anatomists, 6 wer [illegible] 2 British, 1 Czechoslovak and 1 Scandinavian. O [illegible] States, the Middle Atlantic States ([illegible] New Jersey) yielded 20, New E [illegible] al States 12, the West North C [illegible] the country only 10.

Pathologists.—Of the 25 foreign-born pathologists, Canada yielded 8, Britain 4, Germany 3, Russia 3, Austria, France and Switzerland 2 each and Asia 1. In proportion to the number of immigrants in the United States from those countries, the yield was highest from Switzerland, Austria, Russia and Canada. Of those born in the United States, the Middle Atlantic States *yielded 45, the East North Central States 32, New England 31,* the South Atlantic States and the West North Central States each 10, the South Central 9 and the West 3.

Physiologists.—Of the 26 foreign-born physiologists, Canada and Britain each yielded 6, Germany 4, Austria and Russia 2, the Netherlands, Scandinavia, Spain, Switzerland, Africa and Asia each 1. In proportion to the number of immigrants, Austria, Canada, the Netherlands and Switzerland led, with about 1 per 100,000; Britain and Russia did half as well; Germany, one fifth. Of those born in the United States, the East North Central States led with 27, followed by the Middle Atlantic States 23, West North Central States 14, New England States 12, South Atlantic States 10 and the rest 9.

The available information indicates that about a quarter of these distinguished doctors were of Puritan ancestry, a fifth were of other English, about a sixth were Scotch, a sixth German and about 5 per cent each, Dutch and Scandinavian. About 5 per cent of the total were Jewish.

Professor Stephen S. Visher, Bloomington, Ind.

THE BOY SCOUT JAMBOREE

To the Editor:—The international Boy Scout Jamboree, held for this quadrennial at the quiet little village of Moisson, some 40 miles northwest of Paris, and opened officially on August has just closed (August 18). Some 40,000 scouts attended from many different countries. The meeting has proved highly successful and important from many social and international points of view.

Medical interest centers in the facilities organized to cope with surgical, medical and dental needs, mostly of emergency character. The chief in charge was Dr. Francis Lazard, who served in North Africa and Italy and on the southern and Atlantic coasts of France. The Moisson organization included 150 beds for medical cases distributed among three tents, 50 beds for surgery in two tents and two mobile dental units. Two operating rooms were provided and radiologic, laboratory and accessory facilities were available. The equipment was provided by the medical section of the French army. Twenty-five physicians and surgeons were allotted to the hospital service and 20 more were stationed at first aid points distributed throughout the camp.

Occasionally as many as 228 patients (mostly with sore throats) were hospitalized at once. The average number per day was stated as 2 cases. However, the most important service was surgical, the cases largely consisting of arm and leg fractures mainly occasioned through accidents occurring on the belt-line train which circulated throughout and around the camp. There were a few cases of drowning, the camp lying close to a beach in the Seine, and the total mortality is reported at 6 cases.

These details reported were taken from a statement published in the *Jamboree France* of August 19 (the journal issued by the camp authorities and printed in several languages) and also from information supplied by a group of the Scouts.

This is scarcely the place for an essay on the moral, social and political influences which will emanate very fruitfully from this assembly of international youth, but at least its great importance may be briefly stressed, self evident as it is to any careful observer.

Theodore C. Merrill, M.D., Paris, France

Medical Examinations and Licensure

COMING EXAMINATIONS AND MEETINGS

NATIONAL BOARD OF MEDICAL EXAMINERS EXAMINING BOARDS IN SPECIALTIES

Examinations of the National Board of Medical Examiners and the Examining Boards in Specialties were published in The Journal, Oct. 25, page 533.

BOARDS OF MEDICAL EXAMINERS

Alabama: *Examination.* Montgomery, June 22-24, 1948. Sec., Dr. D. G. Gill, 519 Dexter Ave., Montgomery 4.

Arkansas:* *Examination.* Texarkana, Nov. 6-7, 1947. Sec., L. J. Kosminsky, Texarkana. *Eclectic.* Little Rock, Nov. 6. Sec., Dr. Clarence H. Young, 1415 Main St., Little Rock.

California: *Oral.* Los Angeles, Nov 8-9. Sec., Dr. Frederick N. Scatena, 1020 N St., Sacramento 14.

Colorado:* Denver, Jan. 6-9. Final date for filing application is Dec. 20. Sec., Dr. J. B. Davis, 831 Republic Bldg., Denver 2.

Connecticut:* *Examination.* Hartford, Nov. 11-12. Sec., Dr. Creighton Barker, P. O. Box 1438, New Haven.

Delaware: *Examination.* Dover, Jan. 13-15. *Endorsement.* Dover, Jan. 20. Sec., Dr. J. S. McDaniel, 229 S State St., Dover.

District of Columbia:* *Examination.* Washington, Nov. 10-11. Sec., Commission on Licensure, Dr. G. C. Ruhland, 6012 Municipal Bldg., Washington.

Florida:* *Examination.* Jacksonville, Nov. 25-26. Sec., Dr. Harold D Van Schaick, 6675 Windsor Lane, La Gorce Island, Miami.

Hawaii: *Examination.* Honolulu, Jan. 12-15, 1948. Sec., Dr. S. E. Doolittle, 881 S. Hotel St., Honolulu, T. H

Idaho: Boise, Jan. 13-15. Sec., Miss Estella S. Mulliner, 355 State House, Boise.

Indiana: *Examination.* Indianapolis, June 1948. Sec., Board of Medical Registration and Examination, Dr. Paul R. Tindall, K of P Bldg., Indianapolis.

Kansas: Topeka, Dec. 3-4. Sec., Board of Medical Registration and Examination, Dr. J. F. Hassig, 905 N. 7th St., Kansas City.

Maine: Portland, Nov. 12-13. Sec., Dr. A. P. Leighton, 192 State Street, Portland.

Maryland: *Medical Examination.* Baltimore, Dec. 9-12. Sec., Dr. Lewis P. Gundry, 1215 Cathedral St., Baltimore. *Homeopathic Examination.* Baltimore, Dec. 9-10. Sec., Dr. J A. Evans, 612 W. 40th St., Baltimore.

Massachusetts: *Examination.* Boston, Nov. 18-21. Sec., Dr. H. Q. Gallupe, 413-E State House, Boston.

Michigan:* *Examination.* Lansing, Nov. 19-21. Sec., Board of Registration in Medicine, Dr. J. E. McIntyre, 100 W. Allegan St., Lansing 8.

Mississippi: *Endorsement.* Jackson, Dec. 1947. Asst. Sec., State Board of Health, Dr. R. N. Whitfield, Jackson.

Nebraska:* *Examination.* Omaha, Dec. Dir., Bureau of Examining Boards, Mr. Oscar F. Humble, 1009 State Capitol Bldg., Lincoln.

Nevada: Carson City, Nov. 3. Sec., Dr. G. H. Ross, 215 N. Carson St., Carson City.

New Hampshire: *Examination.* Concord, March 11-12. Sec., Board of Registration in Medicine, Dr. John S. Wheeler, 107 State House, Concord.

New York: *Examination.* Albany, Buffalo, New York, Syracuse, Feb. 16-19. Sec., Dr. J. L. Lochner, Jr., Education Bldg., Albany.

North Dakota: Grand Forks, Jan. 6-9. Sec., Dr. G. M. Williamson, 4½ S. Third St., Grand Forks.

Ohio: *Examination.* Columbus, Dec. 2-4. Sec., Dr. H. M. Platter, 21 W. Broad St., Columbus.

Pennsylvania: *Examination.* Harrisburg, Jan. 1948. Acting Sec., Board of Medical Education and Licensure, Mrs. M. G. Steiner, 351 Education Bldg., Harrisburg.

South Carolina: Columbia, Nov. 10-12. Sec., Dr. N. B. Heyward, 1329 Blanding St., Columbia.

South Dakota:* Pierre, Jan. 20. Sec., State Board of Health, Dr. Gilbert Cottam, Capitol Bldg., Pierre.

Texas: San Antonio, Nov. 12-14, 1947. Sec., Dr. T. J. Crowe, 918-20 Texas Bank Bldg., Dallas 2.

Utah: *Examination.* Salt Lake City, June, 1948. Asst. Dir., Department of Registration, Miss Rena B. Loomis, 324 State Capitol Bldg., Salt Lake City.

Virginia: Richmond, Dec. 4-6. Sec., Dr. K. D. Graves, 30½ Franklin Rd., Roanoke.

West Virginia: Charleston, Jan. 12-14. Comm., Public Health Council, Dr. N. H. Dyer, State Capitol, Charleston 5.

Wyoming: *Examination.* Cheyenne, Feb. 2. Sec., Dr. G. M. Anderson, Capitol Bldg., Cheyenne.

---

* Basic Science Certificate required.

BOARDS OF EXAMINERS IN THE BASIC SCIENCES

Arizona: Dec. 16. Sec., Mr. Francis A. Roy, Science Hall, University of Arizona, Tucson.

Colorado: *Examination.* Denver, Dec. 17-18. Sec., Dr. Esther B. Starks, 1459 Ogden St., Denver.

Iowa: Des Moines, Jan. 13, April 13, July 13, Oct. 12. Sec., Dr. Ben H. Peterson, Coe College, Cedar Rapids.

Michigan: *Examination.* Ann Arbor and Detroit, Jan. 9-10. Sec., Miss Eloise LeBeau, 101 N. Walnut St., Lansing.

New Mexico: *Examination.* Santa Fe, Nov. 2. Sec., Miss Marion M. Rhea, 114 E. Marcy, Santa Fe.

Oklahoma: Spring 1948. Sec., Dr. Frank Clinton Gallaher, 813 Braniff Bldg., Oklahoma City.

Oregon: *Examination.* Portland, Dec. 6. Admin., Mr. C. D. Byrne, Univ. of Oregon, Eugene.

South Dakota: Aberdeen, Dec. 5-6. Sec., Dr. G. M. Evans, Yankton.

Wisconsin: *Examination.* Milwaukee, Dec. 6. Sec., Prof. W. H. Barber, Scott and Watson Sts., Ripon.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Photographs: Who Owns Negatives?—The plaintiff filed an action in replevin to recover the negatives of some photographs taken by the defendant, a professional photographer. From a judgment in favor of the plaintiff, the defendant appealed to the Supreme Court, Appellate Term, First Department, New York.

The question involved on this appeal, said the court, is whether, in the absence of an agreement on the subject, negatives belong to the customer or to the photographer. The photographs in question were taken for an agreed price, were delivered and the bill was paid. The plaintiff then demanded delivery of the negatives. Testimony was given that there was an established custom with reference to the retention of negatives; that "it has always been the custom for photographers to retain the negatives." There having been no agreement with respect to the negatives, it would seem that the custom and usage of the industry with respect thereto should prevail. The plaintiff urges, however, that it is established law that the customer has the right to the possession of the negatives. If that is so, any alleged custom or usage to the contrary would be ineffective. Research, said the court, has failed to disclose any case, in this jurisdiction at least, where the ownership of negatives was decided by the court in the absence of an agreement. It is true that the photographer's right to retain the negatives gives him no right to use them for any purpose whatsoever, except at the request of the customer. The photographer, for example, cannot sell the negatives or make photographs from them for any one except the customer. There is nothing inconsistent with proprietary rights in the customer and the holding that the custody of the plates should remain with the photographer. This view would seem to represent the expectations of the party in the absence of any special agreements to the contrary. There are indications in some of the decisions, although no definite adjudication on the subject, that the photographer has the right to retain the custody of the negative. For example, in a case decided in the federal court (*Corliss* v. *E. W. Walker Co.*, 64 F. 280) it was said, "When a person engages a photographer to take his picture, agreeing to pay so much for the copies which he desires, the transaction assumes the form of a contract; and it is a breach of contract, as well as a violation of confidence, for the photographer to make additional copies from the negatives. The negative may belong to the photographer, but the right to print additional copies is the right of the customer." And in an English case (*Pollard* v. *Photographic Co.* [1888], 40 Ch. Div. 345) the court said, "It may be said that in the present case the property in the glass negatives is in the defendant (photographer) and that he is only using his own property for a lawful purpose, but it is not a lawful purpose to employ it, either in breach of faith or in breach of contract."

In conclusion the court held that where a customer employed a photographer to make pictures of him, the photographer, in the absence of any agreement to the contrary, has the right to retain the negatives. He may not, however, make any use of the negatives without the permission of the customer. The judgment in favor of the plaintiff was therefore reversed.—*Hochstadter v. H. Tarr, Inc., 68 N. Y. S. (2d) 762 (New York, 1947).*

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1937 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied with stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted.

Meningitis Caused by Friedlander's Bacillus or Aerobacter Aerogenes: Report of 2 Cases with Autopsies. P. T. Hough and L. Adelson. —p. 534.

Liver Function Tests in Infectious Mononucleosis.—According to Gall, enlargement of the liver, with or without jaundice, is often observed in infectious mononucleosis. The present study was carried out as the result of an accidental observation of an elevated serum phosphatase in a nonjaundiced patient with infectious mononucleosis. Subsequently, 33 patients with this disease were encountered and were investigated with a view to determining the frequency with which phosphatase alteration occurred in infectious mononucleosis. Icterus index, cephalin flocculation and thymol turbidity were also determined. All 34 patients exhibited the blood picture and other clinical manifestations of infectious mononucleosis and all but 1 had heterophil antibody titers of at least 1: 112, a diagnostic level. Only 1 patient was frankly jaundiced, and 2 others exhibited a subicteric hue. Significantly elevated alkaline phosphatase, slightly increased icterus indexes and positive cephalin flocculation and thymol turbidity tests were found whether or not clinical jaundice was present. Alteration in liver function as manifested by these tests was present in almost all patients with infectious mononucleosis.

Perforation of Gallbladder.—Hyman and Steigmann state that postmortem material of biliary tract disease in the Cook County Hospital for the past thirteen years revealed 45 instances of perforation of the gallbladder. In only 10 of the 45 was some type of biliary tract trouble diagnosed prior to death. The correct diagnosis of perforation of the gallbladder was not made in a single instance prior to death. In the other 35 cases there was a variety of diagnoses, the commonest being intestinal obstruction and acute cholecystitis. There were 17 males. This comparatively high incidence of perforated gallbladder in the male is astonishing because of the general belief that disease of of the gallbladder is rare in the male. Over 90 per cent of the patients with perforation of the gallbladder had stones either in the gallbladder or the common duct and over 80 per cent had evidence of chronic cholecystitis. The reasons for delay in surgery in gallbladder disease are procrastination by patients, acquiescence in this by their physicians and uncertainty in the minds of some physicians as to the indications for surgery of the gallbladder.

Intercapillary Glomerulosclerosis.—Henderson and his co-workers report 61 cases of intercapillary glomerulosclerosis in 313 cases of diabetes mellitus. In 30 patients hyalin-like, globular, deeply staining lesions like those originally described by Kimmelstiel and Wilson could be demonstrated and were classified as "advanced." In 31 patients small, deeply staining, club-shaped masses situated in the midst of a diffuse thickening along the axis of the lobule could be demonstrated; these lesions were classified as "early." That intercapillary glomerulosclerosis is not specific for diabetes mellitus at least morphologically is shown by the fact that among 81 cases of glomerulonephritis in nondiabetic patients there were 7 patients with early intercapillary glomerulosclerosis and 3 with advanced lesions. Seven cases with early lesions were observed among 134 cases in which the death of nondiabetic patients was due to hypertension and its complications. Severe lesions were by far the most frequent in diabetes. There were important differences in the clinical behavior in cases of diabetes mellitus and in those of glomerulonephritis in which intercapillary glomerulosclerosis was present. Intercapillary glomerulosclerosis may be considered as a slowly progressive process related to the duration of diabetes mellitus. The diagnosis of intercapillary glomerulosclerosis cannot be established with complete certainty during life, but the condition can be strongly suspected in patients who have diabetes mellitus of long standing associated with albuminuria, hypertension, renal insufficiency and mixed vascular and diabetic retinopathy. The more complex and advanced the retinopathy, the more likely is its association with intercapillary glomerulosclerosis.

Penicillin Blood Levels After Caronamide.—Shaw and his co-workers gave 100,000 units of penicillin and 2.0 Gm. of "staticin" (caronamide, 4'-carboxyphenylmethanesulfonanilide) by mouth every four hours to 6 afebrile patients for six consecutive days. Penicillin was given intramuscularly and caronamide by mouth to an additional 5 patients. The effect of caronamide by mouth on penicillin in beeswax-oil was studied in 3 patients. Each patient served as his own control. During the control phase of forty-eight hours, the patient received penicillin only. This was followed by a period during which the administration of penicillin was supplemented by oral administration of caronamide (the drug phase), followed by a third period when penicillin only was administered (the postdrug control phase). Caronamide inhibited the renal tubular excretion of penicillin and thereby elevated the concentration of penicillin in the plasma from twofold to sevenfold after the oral and/or parenteral administration of penicillin. Caronamide produced no evidence of renal, bone marrow or hepatic impairment, dermatitis or drug fever. These preliminary clinical studies indicate that caronamide should be of definite value in the treatment of disease conditions in which high levels of penicillin in the blood are required.

Atelectasis After Tonsillectomy.—Sawyer reports a case of atelectasis twenty-four hours after tonsillectomy under local anesthesia in a woman aged 25. There was an average amount of bleeding during the operation which was readily controlled without ligatures or stitches. The patient was an actress, high strung and nervous. She was given more than the average preoperative sedation. Despite this she did not sleep after the operation and was given 0.011 Gm. of "pantopon" (a mixture of hydrochlorides of opium alkaloids) three and a half hours postoperatively. Her sedation plus her fear of pain from coughing may have favored the inspiration of blood and saliva which acted as a nucleus. Bronchoscopy was performed and the right main bronchus was found to contain a bloody mucous plug which was aspirated. The patient showed considerable improvement immediately. She was discharged on the sixth postoperative day in good condition. Bronchoscopy with visual aspiration is one of the safest and best methods of treating collapse of the lung.

Insufflation of Sulfonamide Drugs.—Ballenger applied sulfathiazole, sulfanilamide and sulfadiazine powders, alone or in combination, by insufflation to the mucous membrane of the upper respiratory tract in 1,500 patients with various acute infections of the nose and throat. Six thousand applications were made during a three year period from July 1, 1943 to July 1, 1946. An average of about 2.5 treatments were given for each acute attack. Many of the patients have had two, three or more attacks during the three year period. The sore throat and inflammation, especially that of the palate, nasopharynx and pharynx, were frequently stopped within twenty-four hours. The rhinitis and the cough would continue to develop in many patients but not in as many as had been formerly observed. The numbers in whom sinusitis and the various forms of otitis developed were definitely lessened when compared with the numbers of patients not so treated in whom these complications appeared. The greatest value of the insufflation of the powdered sulfonamide compounds appeared to be in the first three or four days of the acute infection. Insufflation of the sulfonamide compounds proved to be as safe as their oral use. Only 7 out of the 1,500 treated gave evidence of sensitivity as manifested by dermatitis, hives or hay fever–like symptoms.

Penicillin and Sulfonamide Drugs in Acute Hematogenous Osteomyelitis.—Mathews and Hutter present a comparative study of the effectiveness of the sulfonamide compounds alone and of the sulfonamide compounds and penicillin combined in the treatment of 25 cases of hematogenous Staphylococcus aureus osteomyelitis at the Children's Hospital, Los Angeles. The expected mortality rate of penicillin-treated cases of osteomyelitis should be less than 1 per cent; the course of the disease is considerably shortened; the roentgenograms reveal less destruction in these cases and the necessity for surgical intervention and drainage of bone abscesses has been reduced. The authors stress the importance of repeated hemoglobin determinations, red blood cell counts, white blood cell counts and differential counts, urine examinations and blood cultures. Transfusions of 150 to 200 cc. should be given daily or at least once a week, depending on the hemoglobin content. Penicillin should be administered by the intravenous route in doses of 400,000 units daily for the first two days, then in somewhat smaller dosage. Sulfadiazine should be given in amounts to maintain a blood level of about 12 mg. per hundred cubic centimeters of blood. A high dosage may be necessary to secure this blood level. Positive fluid balance with adequate output of urine should be insured by intravenous administration of fluids if necessary. The affected parts should be immobilized and a diet high in vitamins should be provided.

Asphyxial Death Due to Pulmonary Cryptococcosis.—Moody reports the case of a Mexican laborer, aged 38, who was admitted with the probable diagnosis of pulmonary tuberculosis, submiliary type. His chief complaint was shortness of breath of fifteen days' duration. He had lost 13 pounds (5.9 Kg.) in weight during the preceding two months, had started coughing one month before entry and had been bringing up a mucoid sputum with the cough. Three examinations of sputum were made for tubercle bacilli and none was found. Roentgenoscopy suggested a submiliary lesion, possibly tuberculous, and pleuritis with adhesions and fluid at the base of the right lung. Later, obstruction of a major bronchus or a tracheal obstruction was suspected. Bronchoscopic examination disclosed a fungating tumor mass below the larynx. Treatment was largely symptomatic. The patient died on March 24, although nearly 1,000,000 units of penicillin and 390 grains (23.4 Gm.) of sulfadiazine had been given. Sections of cystlike masses and smears of the mucinous material from the bronchi contained many encapsulated organisms characteristic of Cryptococcus neoformans (Torula histolytica). There were additional lesions of cryptococcosis in sections from several different areas of each lung. Areas of silicosis were also demonstrated in sections, but no tuberculosis was found. The organisms (C. neoformans) were numerous and easily demonstrated by direct wet smears mixed with a small amount of india ink. The mucinous capsules of the organisms with their included centrally located yeastlike bodies could be clearly seen.

Inhalation Therapy.—Levine treated 42 patients, 26 men and 16 women, of the average age of 50 years, with inhalation of a nebulized solution of penicillin for chronic bronchial infection. The following criteria were used in selection of cases: (*a*) definite bronchographic evidence of bronchiectasis; (*b*) a history which is definitely of this type of infection for a long period of time; (*c*) previous treatment of all the patients by all other methods, including rest in bed, postural drainage, sulfonamide drugs by mouth and penicillin by injection. All of the patients have been followed for at least one year. Symptoms disappeared completely in 19 of the 42 patients; 14 patients showed pronounced improvement in symptoms and general condition and 9 did not present any clinical improvement. Recurrence of symptoms with an entirely new bacterial flora suggesting a new infection was the rule rather than exception. The sensitivity of the organism to penicillin was the more important factor in the determination of the result. The concentration of penicillin per cubic centimeter in the nebulized solution did not appear to be an important factor per se. Inhalation therapy has a definite value in the treatment of bronchial infection while continued medical supervision and customary treatment, including postural drainage, remains an essential element.

Treatment of Bronchial Adenoma.—Bronchial adenoma, according to Goldman, is a slowly growing epithelial tumor which is locally invasive, clinically benign, but apparently capable in rare instances of becoming malignant. According to this concept, patients with bronchial adenoma between the ages of 24 and 48 were treated with pulmonary resection. There was 1 surgical death from infection. Results were satisfactory in the remaining 9 cases and were superior to bronchoscopic removal in treatment of patients with bronchoscopically inaccessible and large tumors, with recurrent tumors following bronchoscopic removal, with distal pulmonary suppuration and with involved mediastinal lymph nodes. No metastases have occurred in any of these 9 patients, although in 3 the tumor was left in the pulmonary stump without apparent spread. With modern preoperative and postoperative care, intratracheal anesthesia and surgical technic for conservation of the upper lobe applicable to adenomas located in a stem bronchus and accomplished by combining lobectomy with bronchotomy, pulmonary resection is the method of choice for the treatment of benign tumors of the lung.

Epilepsy in Old Age.—According to Brown epilepsy is thought to be an inherent, inherited abnormality of the nerve cells of the brain or paroxysmal cerebral dysrhythmia. In the absence of cerebral injury, it would seem unlikely that the onset of cerebral dysrhythmia in the aged would be due to age alone. The case histories of the 2 patients presented here would seem to bear this out. One of the patients was a woman, aged 61, and the other was a man, aged 71 when the seizures started. Each had a sibling who had epilepsy. Neither of the patients had retinal arteriosclerosis, hypertension, glandular dysfunction or Stokes-Adams disease. In both patients recent memory had been poor since the onset of convulsions. There were no abnormal neurologic signs or psychotic behavior. The electroencephalogram of 1 patient was normal and that of the other was abnormal only after hyperventilation. The symptoms of idiopathic epilepsy may begin at any age. The probable cause lies in an inherent dysrhythmia of the cerebral nerve cells.

Enhancement of Blood Levels of Penicillin by Caronamide.—Beyer reported that the excretion of penicillin could be inhibited by 4′-carboxyphenylmethanesulfonanilide, a compound called caronamide. Seeler and his co-workers administered caronamide orally to patients over 60 years of age in doses of 2 Gm. every four hours and noted an enhancement of the plasma penicillin levels resulting from the intramuscular administration of 100,000 units of penicillin every eight hours. It was necessary to increase the caronamide dosage to 4 Gm. every four hours to produce a similar effect in younger persons. The penicillin blood levels following intramuscular administration of 100,000 units of penicillin every eight hours to patients receiving approximately minimal effective oral doses of caronamide were significantly higher than those obtained by giving 300,000 units of penicillin alone to similar subjects.

Caronamide and Sodium Benzoate for Enhancement of Penicillin Concentrations.—Strauss and his co-workers studied the effectiveness of caronamide (4′-carboxyphenylmethanesulfonanilide) in enhancing the plasma penicillin concentration in 35 adult subjects. The effect was compared with that of sodium benzoate. The only toxic effects of caronamide were nausea and mild diarrhea in a few persons. When 100,000 units of penicillin were given by mouth concurrently with caronamide, a twofold or greater increase in plasma penicillin concentrations were observed in 80 per cent of the blood samples and a fourfold or greater increase in 40 per cent of the samples. This enhancement of the plasma penicillin concentration was maintained for two hours but not for three hours after each dose of penicillin. The concurrent oral administration of caronamide in subjects who received 25,000 and 50,000 units of penicillin intramuscularly likewise resulted in twofold to eightfold increases in plasma penicillin concentrations in most instances. The effects of caronamide were variable when penicillin was injected in peanut oil and beeswax, but plasma penicillin concentrations were in the majority of instances increased. Caronamide had no effect on the plasma concentration of streptomycin when the latter substance was administered in multiple intramuscular injections. In general sodium benzoate was as effective as caronamide in increasing plasma penicillin concentrations when penicillin was given by mouth or by intramuscular injection. The ingestion of both sodium benzoate and caronamide by subjects receiving penicillin by mouth resulted in a greater enhancement of plasma penicillin concentration than was effected by either of these agents alone.

Replacement of Free Bone Plates in Craniotomies.—Ray and Parsons think that the routine use of free bone plates, *completely separated from* dura, pericranium and muscle, and their replacement in the ordinary craniotomy have not been thoroughly evaluated. They began several years ago to replace revised free bone plates in cases in which the skull was involved by tumors such as osteomas and meningiomas and in which discarded bone would have left unsightly defects. They draw the following conclusions from the study of 100 consecutive cases in which there has been immediate or delayed replacement of untreated or boiled cranial bone plates: 1. The use of free bone plates in routine craniotomies has technical advantages over the use of the classical osteoplastic flap. 2. The survival of the free bone plate that is normal and immediately replaced compares favorably with that of the bone in the osteoplastic flap. 3. There is no greater incidence of infection than in the osteoplastic flap. 4. Postoperative bleeding from the bone plate is eliminated. 5. Boiling the bone plate does not significantly increase its tendency to atrophy provided that it is replaced immediately. 6. The delayed replacement of boiled bone should be avoided, since it is accompanied by an increased tendency for wound infection and atrophy of the bone. 7. Tumor tissue in the bone plate can be killed by boiling but plates extensively invaded by tumor do not survive well when boiled and replaced.

Ectopic Pinealomas in Chiasmal Region.—Horrax and Wyatt report 3 cases of so-called ectopic pinealomas in the chiasmal region. All 3 patients were Jewish boys between 12 and 19 years of age. In 2 of the patients a primary pinealoma in the pineal region was present and verified microscopically. In 1 of these patients the chiasmal growth was shown to have come by direct extension from the pineal tumor through the wall of the third ventricle; in the other, such an extension was presumed but could not be verified. In the third patient there has never been any clinical evidence of a primary tumor in the pineal region. In 2 of the patients diabetes insipidus was the outstanding clinical complaint. The chiasmal tumor was removed radically at operation in 2 instances, and 1 patient is alive and well after four and one-half years. In view of Dorothy Russell's thesis that ectopic pinealomas are in reality teratomas, serial studies on the material available were carried out in these 3 cases, but in only 1 was there any suggestion of a teratomatous origin, and here the visual proof was not conclusive. The other 2 cases are classical pinealomas from the histologic aspect, with the first case showing regional spread to the pituitary and hypothalamic regions.

Acute Poliomyelitis in Pregnancy.—The Bakers say that during the Minnesota poliomyelitis epidemic in the summer of 1946, 695 patients with acute poliomyelitis were admitted to the Minneapolis General Hospital. Of this group, 115 were women of child-bearing age, 30 of whom were pregnant. The ages of the pregnant women varied between 17 and 32 years. Stages of gestation at the time of admission varied between six weeks and nine lunar months. Fifteen live babies had been delivered by March 15, 1947. Seven spontaneous abortions and 6 deaths occurred among the 30 pregnant patients. The authors conclude that poliomyelitis occurs in the pregnant woman more frequently than can be attributed to mere chance. In general pregnancy has little influence on the course of poliomyelitis or the extent of paralysis. There is a relatively high percentage of abortion (30.4 per cent) among pregnant patients with poliomyelitis. This study produced no evidence to show that the fetus can or cannot contract poliomyelitis in utero.

Congenital Diaphragm of Duodenum.—According to Nelson congenital diaphragm of the duodenum is a developmental anomaly in which a membrane formed by an infolding of the mucosa and submucosa extends across the lumen of the duodenum. The diaphragm may be complete or it may present an aperture. Cases of a duodenal diaphragm without an aperture are instances of congenital high intestinal obstruction. Unless the obstructions are recognized and successfully operated on, the infants die during the first few days of life. Those with small apertures in the diaphragm may have no symptoms, but they are potential candidates for complete obstruction. Nelson found 35 cases of congenital diaphragm of the duodenum reported in the literature, only 6 of which were recognized during life; of these, 5 were cured. He reports the case of a woman aged 26 in whom roentgenologic studies permitted the preoperative diagnosis. The patient was cured by resection of the duodenal diaphragm. Dilatation of the proximal duodenum demonstrable by roentgen ray has been reported in this condition by others. The roentgenograms of the author's case showed clearly a congenital diaphragm forming a sacculation within the duodenum. Duodenotomy and excision of the membrane is advocated rather than short-circuiting procedures.

Mesenteric-Artery Embolism.—p. 135.

Radical Surgery in Recurrent Cancer of Colon.—Dunphy maintains that since surgical intervention is the only way to treat cancer of the colon initially, it should be employed whenever possible in dealing with recurrences. If there is no positive evidence of distant metastases or generalized peritoneal seeding, reoperation should be considered regardless of the extent of the first operation, the histologic character of the growth or the apparent fixation of the recurrence. He reports 4 cases selected as examples of what may be accomplished by a second attempt at extirpation of carcinomas of the colon and rectum that have recurred locally. Gratifyingly long periods of arrest may follow such operations.

Infectious Hepatitis Associated with Pregnancy.—According to Martin and Ferguson an epidemic of infectious hepatitis began among the civilian population of Portland, Maine, during 1944 and has continued to date. Four cases occurred in pregnant women. No definite conclusions can be drawn from this small series. The danger of maternal death from hepatitis is small. The chance of an uneventful pregnancy is poor, and there is a possibility of prolonged jaundice and perhaps permanent hepatic damage in the mother. Improvement in the mother occurred soon after the cesarean section in case 1 and soon after delivery in case 2. It appears that the mother benefits from removal of the fetus. Pregnancy itself may place an extra strain on an already diseased liver. Interruption of the pregnancy should be seriously considered in severe cases of hepatitis unless the patient improves rapidly under observation. Little other treatment will benefit, since treatment in infectious hepatitis has always been purely symptomatic.

Decompression Sickness.—Catchpole and Gersh demonstrate that the evidence is overwhelming that gas bubbles are the primary pathogenetic agent in decompression sickness. Whether they occur after decompression from high pressure atmospheres or to altitude, gas bubbles are chiefly intravascular and are held to be responsible for nearly all important phases of the syndrome of decompression sickness. Extravascular gas bubbles occur also in certain severe instances of decompression from high pressure atmospheres, but they are restricted to certain lipid-rich structures. The pathologic effects may be vastly greater after decompression from high pressure atmospheres than to altitude.

Fatal Case of Primary Diphtheria of Cervix and Urethra.—Bottomley and Christie report the case of a woman who two days before admission to the hospital had an illness of influenza type, with a temperature of 104 F. Her last menstrual period began eight days before admission and had been normal until the onset of her illness. She was tender in both iliac fossae. Bacteriologic examination revealed Corynebacterium diphtheriae mitis in cervix and urethra. Antidiphtheritic serum was started, as well as intramuscular administration of penicillin, but polyneuritis and myocarditis were evidently already present when treatment was started. After treatment, clearance swabs from the cervix were negative, but the patient's general condition deteriorated. The myocarditis progressed. The patient had a vagal block attack and died. At the time of the diagnosis of diphtheria the patient was questioned as to possible contacts. She stated that her betrothed had shared a cell with a man who had diphtheria. The route of infection in a primary case of genital diphtheria is a matter for speculation, but it appears possible that it may sometimes be transmitted by sexual intercourse.

Creatinine Losses in Hot Humid Environments.—Ladell found that whereas the creatinine contents of both the saliva and the blood increase threefold after a dose of 5 Gm. of creatinine, there is only a slight increase in the creatinine content of the sweat. The creatinine of the sweat appears to be more closely linked with the rate of sweating than with the level of creatinine in the blood; thus the slower the rate of sweating the greater the creatinine content. This reciprocal relationship between creatinine content and sweat rate is the opposite of what has been observed for chloride concentration. There appear to be two mechanisms involved in the production of sweat from body fluids. Mosher's suggestion that there is an essential similarity between sweat and urine may be correct, but the fact that the creatinine content of the sweat is little affected by that of the blood, whereas the urinary creatinine is greatly affected, indicates that the production of the two fluids must be different.

*Mud Fever. J. H. Bekker and T. S. J. A. Bonga.—p. 1713.

Reduction of Serum Potassium Content with Generalized Muscular Weakness During Diabetic Coma.—While treating a patient with severe diabetic coma with large quantities of insulin, water, dextrose, sodium chloride and sodium bicarbonate, Frenkel and his associates observed muscular weakness, partial respiratory paralysis, water hammer pulse with irregular rhythm, increased pulse pressure, cardiac dilatation with a systolic murmur and increased venous pressure. The serum potassium level, which had been normal on admission, decreased to 6.9 mg. per hundred cubic centimeters. The symptoms disappeared after administration of potassium. The authors consider this syndrome an expression of general muscular insufficiency as a result of potassium depletion. They discuss the mechanism which causes this decrease in serum potassium and emphasize the importance of recognizing this dangerous condition in the treatment of diabetic coma.

Mud Fever.—Bekker and Bonga review the history of mud fever in the Netherlands and report clinical histories of 2 farmers who contracted this form of leptospirosis. It was found that the burrowing mice (voles) which infested the ground on the farms were infected with Leptospira grippotyphosa.

*Primary Dysmenorrhea Treated with Dilation of Neck of Uterus and with Sympathectomy: After-Examination of 195 Patients. K. Knutsen. —p. 1261.

Hygiea

Asphyxia in New-Born. Y. Åkerrén.—p. 1269.

Primary Dysmenorrhea Treated with Dilation of Neck of Uterus and with Sympathectomy.—Knutsen states that dilation of the neck of the uterus with Løvset's dilator is safe. Good results were obtained for over a year in about 50 per cent of the 125 patients treated; eliminating as far as possible the effect of pregnancy on the dysmenorrhea, the results were good in 46 per cent. They were about the same in patients with infantile uterus and with uterus of normal size. Resection of the superior hypogastric plexus is accompanied by the same risk as other laparotomies and should be carried out only in grave and stubborn cases of primary dysmenorrhea in which other safe methods of treatment, particularly dilation of the cervix, have been tried or in which laparotomy is indicated for other reasons. Typical uterine dysmenorrhea lends itself to this treatment. Of 75 patients treated by this method 1 died postoperatively. Of the 70 followed up, sympathectomy alone was done in 44 and sympathectomy with correction of minor pelvic abnormalities in 26, with good results in 84 and 92 per cent, respectively. The failures are attributed to incomplete resection. Examination of the resected tissue should be made; while the presence of nervous tissue does not guarantee complete resection, its absence indicates the need for further resection. Pregnancy and delivery are not unfavorably affected by the resection.

Vitamin A and Hypervitaminosis D. Suzanne Dreyfus-Neumann. —p. 1617.

Puncture of Spleen and Coupled Punctures.—According to Weil and Perlès splenopathy is not always associated with definite alterations in the blood and the bone marrow. In such cases punctures of the spleen, the liver and the bone marrow will be of considerable aid in diagnosis. There are other cases for which the term cryptopathology of the spleen has been suggested, such as lymphatic leukosis with a normal or subnormal blood picture, or rare cases of myelogenous leukosis without changes in the blood. Splenic puncture will be of definite help and other punctures will reveal whether or not the liver and the bone marrow are taking part in the neoplasia. Splenic puncture may clarify the diagnosis in cases of chronic cryptoerythroblastosis. In Gaucher's and in Niemann-Pick's disease puncture of the liver and the bone marrow may reveal involvement of their parenchyma with tumor cells. Combined punctures in splenomegaly associated with kala-azar and malaria demonstrate that disease of the spleen presents only one aspect of a more important involvement of the reticuloendothelial system. Splenic puncture will help the surgeon to decide whether or not splenectomy is indicated. Twenty-four hours of rest in bed with ice applied to the abdomen should always precede splenic or hepatic puncture. Combined subcutaneous injections of epinephrine and ephedrine five minutes before the puncture are recommended for patients with a mild tendency to hemorrhage and additional subcutaneous injections of 5 to 10 cc. of blood to patients in whom this tendency is more definite. To prevent severe unexpected hemorrhage, splenic puncture should be adopted in addition to coagulation tests as a routine measure.

Lymph Nodes Perforating Into Trachea and Bronchi.—According to Justin-Besançon and his co-workers bronchoscopic examination has demonstrated that tuberculous lymph nodes may perforate into the trachea and the bronchi and that the consequence of such perforation may often be less grave than was formerly believed. Perforation of primary infection of the lymph nodes in children and in adults must be distinguished from that of adenopathy due to reinfection or calcification of lymph nodes. These conditions differ from one another with regard to prognosis, manifestations and incidence. Dissemination over the subjacent pulmonary parenchyma is the principal danger associated with perforation of lymph nodes. Its occurrence is far from being a rule. It is usually associated with deposition of liquid caseous material which contains a large number of Koch's bacilli. Fatal hemoptysis may occur in adults from perforation of lymph nodes into a bronchus with an adherent diverticulum of the esophagus or from ulceration into large mediastinal vessels. The passage of small concretions from the calcified lymph nodes into the trachea and the bronchi as the cause of mild and unspecific inflammatory changes should be taken into consideration to avoid an erroneous diagnosis of bronchopulmonary suppuration or cancer of the lungs.

Recent Advances in Clinical Pathology. By Various Authors. General Editor: S. C. Dyke, D.M., F.R.C.P. Section Editors: Bacteriology, R. Cruickshank, M.D., F.R.C.P.; Biochemistry, E. N. Allott, B.Sc., B.M., B.Ch.; Haematology and Cytology, B. L. Della Vida, M.D.; Histology, A. H. T. Robb-Smith, M.D. Produced Under the Auspices of the European Association of Clinical Pathologists. Fabrikoid. Price, $5.50. Pp. 468, with 53 illustrations. Blakiston Company, 1012 Walnut St., Philadelphia 5; Spottiswoode, Ballantyne & Co., Ltd., 1 New-Street Sq., London, E. C. 4, [1947].

This volume is a collaborative effort of forty-one pathologists, mostly British, some from various European countries who found refuge in England from persecution in their native lands. Dyke, the editor, pays tribute to these refugees for their contributions to building up the British service in clinical pathology during the war. The gathering of pathologists from the entire continent led to the formation of the European Association of Clinical Pathologists. When the time seemed near that those who came from abroad might be able to return to their homes, the publication of this book was decided to put on record "the present state in Great Britain of the knowledge and practice of Clinical Pathology." The text is divided into four main sections: bacteriology, biochemistry, hematology and cytology, and histology. Each of the chapters deals with subjects in which important recent advances have been made. They include enteric infections, typhus fever, sore throat, primary atypical pneumonia, pertussis, tuberculosis, brucellosis, anaerobic, staphylococcic, leptospiral and venereal infections, classification of streptococci, laboratory control of chemotherapy, liver function tests, prothrombin time, gastrointestinal diseases, Addison's disease, nutritional deficiencies, sulfonamides, photoelectric colorimeters, and micromethods of blood analysis, hematologic nomenclature, the myelogram, sedimentation rate, pernicious anemia, semen, sputum, pleural fluid, aspiration biopsy, cell counts in serial biopsies of carcinoma, biopsy of lymph nodes, testes, endometrium, skin and peripheral nerves, wet film technic in neurosurgery, clinical and postmortem pathology of encephalitis, and modern histologic technics. Each chapter is a separate and independent unit. The presentation is lucid. Dr. Dyke is to be complimented for a fine editorial job, not an easy accomplishment in view of the heterogeneity of material in a small volume dealing with forty-one subjects by the same number of authors. Physicians in all specialties will find in this book a great deal of valuable information.

Medical Jurisprudence. By W. F. Rhode, B.A., M.B., Ch.B., Government Pathologist, Union Health Department, Cape Town, I. Gordon, M.B., Ch.B., Senior Assistant Government Pathologist, Union Health Department, Cape Town, and R. Turner, M.B., Ch.B., D.P.H., Special Serologist, Union Health Department, Cape Town. With additional contributions by Prof. M. R. Drennan and others. Foreword by the Hon. Mr. Justice H. S. Van Zijl. Second edition. Cloth. Price, 32s. 6d. Pp. 512, with 77 illustrations. Cape Town: Published for the Post-Graduate Press by the Stewart Printing Co. (Pty.) Ltd., 194.

This edition of a book first published in 1942 deals with medical jurisprudence in South African criminal law. It is designed to serve as a practical manual to students, district surgeons and others of that country concerned with medicolegal problems. The authors have collected in it the statutory provisions which are of especial importance to medical practitioners. Several new chapters have been added in this edition, including one on identity, one on the medicolegal aspects of mental illness and another on the medicolegal aspects of workmen's compensation. New sections have also been added relating to the constitution and functions of the South African Medical Council, the registration and certification of births and deaths, and the keeping and sale of poisons and habit forming drugs.

Home Guidance for Young Children: A Parents' Handbook. By Grace Langdon [Grace Langdon Ackerman]. Second edition. Cloth. Price, $4. Pp. 357, with illustrations. John Day Co., Inc., 11 6th Ave., New York 13, 1946.

This complete revision of the edition published in 1931 is intended primarily as a handbook and reference for parents on the care and training of the infant and young child. All aspects of the child's growth and development are treated in detail. The material is divided into nine basic units, including the prenatal period, the first twelve or fifteen months, eating, sleep and rest, toileting, play, living with other people, school days and summary. Each topic is divided into sections dealing with the common problems encountered in the guidance of children. A list of suggested references at the end of each chapter provides for supplementary reading. Practical suggestions for preventing difficulties which may be associated with child development are offered and methods of dealing with those that do occur are described. All the activities of the child are regarded as a part of learning, with emphasis placed on intelligent utilization of the child's experiences to promote normal social, physical and mental growth. While not discarding time tested information, a sensible point of view in relation to implications which may be drawn from recent studies in child growth and development is presented. The author points out that reasonable parents will be honest and positive in their approach to the problems of their children. They will enjoy parenthood through careful study of the child as an individual who deserves real respect as well as love and security. The book is essentially of manual type with a style not unlike that of college textbooks. It is well organized and printed but could with profit include more of the excellent illustrations found in the section on "the first twelve or fifteen months."

P-Q-R-S-T: A Guide to Electrocardiogram Interpretation. By Joseph E. F. Riseman, M.D., Associate in Medicine, Harvard Medical School, Boston, Massachusetts. Second edition. Cloth. Price, $3.50. Pp. 84, with 31 illustrations. Macmillan Company, 60 Fifth Ave., New York 11, 1947.

The demand for a simple presentation of electrocardiography suitable for the beginner has led to the publication of a number of compends. The present volume, which has gone into a second edition within three years, is among the best. Of course it has all the faults, as the author recognizes, that come with an attempt to condense a large mass of data into a small space. The text is illustrated with diagrams, some of which are inaccurate, e. g. that on auricular flutter on page 19, that on digitalis T waves on page 41 and the chest lead of left and right heart strain on page 55. It is regrettable that the author suggests that the electrocardiogram may be taken on a seated patient. It is an error to consider that an ST depression of any extent in the chest leads is normal; it is also an error to consider that premature beats of the sinus node are frequent and that the voltage of T is significantly influenced by the strength of the heart beat. The illustrative electrocardiograms used at the end of the text lose some of their value because of their sharp reduction. Case 16A is an instance of almost complete auriculoventricular block and shows no premature systoles. This record is much too complex for an introductory textbook. The term "slight bundle branch block," as stated for example in case 9, is not to be recommended. It is regrettable that the author does not promulgate the use of multiple chest leads to a greater extent. It appears that he has much less experience with them than with the limb leads. Several features are to be commended, viz. the glossary at the end, the hints on errors which might readily occur in taking electrocardiograms and the diagrams relating the several electrocardiographic deflections with the status of the heart at the time. On the whole, the booklet is recommended.

The Psychoanalytic Study of the Child. Volume II. 1946. An Annual. Managing editors: Anna Freud, Heinz Hartmann, M.D., and Ernst Kris, Ph.D., Cloth. Price, $7.50. Pp. 424. International Universities Press, 227 W. 13th St., New York 11, 1947.

This volume of the annual has five sections devoted respectively to problems of child development, clinical problems, guidance work, problems of education and sociology and history of child psychiatry. Although the annual is written for dynamically trained psychiatrists, this volume contains papers which will be of interest to many physicians who recognize the importance of psychologic and psychiatric difficulties in the child. Pediatricians will find many of the clinical papers rewarding. Anna Freud's contribution "The Psychoanalytic Study of Infantile Feeding Disturbances" is a simple and lucid presentation, which would be intelligible to any pediatrician and contains many helpful suggestions concerning the management of feeding difficulties in infants. The chapter by Dr. Margaret W. Gerard on "The Psychogenic Tic in Ego Development" has fascinating, well presented clinical material which throws light on the genesis of psychosomatic symptoms by a psychologically traumatic experience. Dr. Phyllis Blanchard's contributions to the "Problems of Reading Disabilities" and Dr. Elizabeth R. Geleerd's "Psychoses in Childhood" will be interesting reading for the pediatrician. The other sections of the annual are concerned with more theoretical problems. The chapters on "Twins" by Dorothy T. Burlingham and "The Child's Laughter" by Edith Jacobson are worth the reader's attention. Pediatricians, educators, psychologists and social workers will all find in this annual clinical and theoretical formulations which will enlarge and can be integrated into their own special fields.

L'anesthésie intra-veineuse au pentothal-sodium. Par Ernest Kern. Préface de R. Merle d'Aubigné. Paper. Price, 100 francs. Pp. 93. Masson & Cie, 120 Boulevard Saint-Germain, Paris 6ᵉ, 1946.

This monograph surveys the present status of pentothal sodium for surgical anesthesia. The author became interested in the qualities of the drug while serving with the Allies during the war. His experience covered more than 3,000 persons wounded in battle to whom pentothal sodium was administered. Increasing use of this agent in civilian practice convinces the author that pentothal sodium is a valuable addition to the armamentarium of the French anesthetist. A short history of the intravenous use of barbiturates is given. The physical and chemical properties of pentothal sodium are discussed briefly. A short chapter covers the physiologic effect of the drug. A chapter is given over to the discussion of the complications which follow the use or misuse of pentothal sodium. Two cases are reported in detail. Treatment of complications during or following the use of pentothal sodium is discussed in the same chapter. The clinical uses of pentothal sodium, with suggestions about premedication, dosage and use of oxygen are the subjects of a short chapter. One case is reported. A longer chapter gives the various technics by which pentothal sodium may be used. One case is recorded in which respiratory arrest was overcome with artificial respiration and oxygen insufflation. Greater detail regarding accidents and dosage is included in this chapter. Various combinations of pentothal sodium and inhalation anesthetics are outlined, with a precautionary paragraph on the danger of combining chloroform and pentothal sodium. About a third of the book is given to the discussion of the contraindications for the use of pentothal sodium. Thirty-six cases are reported to illustrate various subjects in this chapter. A comparison of pentothal sodium and hexobarbital soluble (evipal sodium) concludes the text. A short bibliography of references written in French on the subject is followed by a short bibliography of references in English. The book contains no index. Much material is presented in concise form.

School Health Problems. By Laurence B. Chenoweth, A.B., M.D., Professor of Hygiene, University of Cincinnati, and Theodore K. Selkirk, A.B., M.D., Assistant Professor of Clinical Pediatrics, College of Medicine, University of Cincinnati. With an Outline on School Health Administration. By Richard Arthur Bolt, M.D., Dr.P.H. Third edition. Cloth. Price, $3. Pp. 419, with 116 illustrations. F. S. Crofts & Co., 101 5th Ave., New York 3, 1947.

Though the same general plan has been followed in this edition as in the previous editions of this useful little volume, all the material has obviously been thoroughly revised and brought up to date. Both sides of controversial issues are fairly represented, and the reader is permitted to make his own choice. The thesis that "the major objective of all medical service in the school is educational" is presented and well supported. Though the reader might be inclined to question the author's acceptance of foot baths for controlling ringworm infection of the feet and to have some reservations as to the recommendations related to schoolroom illumination, he finds the answers here suggested for school health problems to be generally sound, well considered and in line with the best of modern medical thought. The illustrations leave something to be desired, and the explanation of the Wetzel grid method for evaluating physical fitness is definitely not clear. In general, however, the facts are represented accurately, interestingly and fairly, and the volume is highly recommended for all physicians doing any work in the schools.

Vascular Disorders of the Limbs Described for Practitioners and Students. By Sir Thomas Lewis, C.B.E., F.R.S., M.D., Physician in Charge of Department of Clinical Research, University College Hospital, London. Second edition. Cloth. Price, $2.25. Pp. 118, with 5 illustrations. Macmillan & Co., Ltd., 60 Fifth Ave., New York 11; 10 St. Martin's St., Leicester Sq., London, W. C. 2, 1946.

This volume, by a recognized authority on the physiology of the peripheral circulation, is not a complete treatise on peripheral vascular diseases. Conspicuous by its absence is consideration of such diseases as venous thrombosis, aneurysm and periarteritis nodosa. The anticoagulants heparin and dicumarol are not discussed. In general, clinical description of diseases is brief and inadequate. Treatment is lightly presented. As an example, one page is devoted to the treatment of arterial embolism and thrombosis; about three fourths of this is discussion of embolectomy. There is no bibliography or photographs. Because of these deficiencies the book has no great value for practitioners; the title is somewhat deceptive. However, the volume has great value for the student and the curious; it is essentially a consideration of physiology. There is excellent presentation of the causes of various colors of the skin which are circulatory in origin. The effects of arrest of arterial circulation are discussed thoroughly. The chapters on vasoconstriction, local arterial spasm, Raynaud's disease, Raynaud's phenomenon and vasodilatation will be helpful to the student of physiologic disturbances of the peripheral circulation. The volume is highly recommended from the point of view of presentation of fundamental studies in physiology by the author and his students.

A Program for Hospitals of the Pittsburgh Area Based on a Study of Voluntary Hospitals in Allegheny County and Adjacent Counties. By Abraham Oseroff. Sponsored by the Hospital Council of Western Pennsylvania. Paper. Pp. 38, with 2 illustrations. The Council, 814 Farmers Bank Bldg., Pittsburgh 22, 1947.

This pamphlet summarizes a study of the voluntary hospitals in a ten county area surrounding the metropolitan center of Pittsburgh. The survey, sponsored by the Hospital Council of Western Pennsylvania, is concerned mainly with hospital needs, the distribution of existing facilities, the financial picture of hospitals in this area, the current program of hospital activities and estimates of future expansions in the scope of hospital service. It is anticipated that a further report will be made on a larger study that has been carried out on all voluntary hospitals in western Pennsylvania.

Trauma in Internal Diseases: With Consideration of Experimental Pathology and Medicolegal Aspects. By Rudolf A. Stern, M.D. Foreword by Francis Carter Wood, M.D., Director of Laboratories and Radiotherapy Department, St. Luke's Hospital, New York. Cloth. Price, $6.75. Pp. 575. Grune & Stratton, 44 Fourth Ave., New York 16, 1945.

The author has assembled a series of case histories, some with exhaustive postmortem findings, reflecting the causal relationship or lack of such relationship between nonperforating trauma and internal diseases. The scientific literature is subjected to a critical review, and there is presented a description of experimental work which has either confirmed or refuted the assumption of trauma as an etiologic factor for many internal diseases. The book should be of aid to physicians in the medical evaluation of cases that involve disability or compensation claims based on internal lesions due directly or indirectly to extrinsic injury.

Health Facts for College Students: A Textbook of Individual and Community Health. By Maude Lee Etheredge, M.D., D.P.H. Fifth edition. Cloth. Price $2.50. Pp. 439, with 75 illustrations. W. B. Saunders Co., West Washington Square, Philadelphia 5, 1947.

This edition is interestingly written and well organized. The text appears to be up to date in every respect. Though the table of contents would seem to indicate a rather limited inclusion of materials on community health, much of such material has been integrated throughout the volume.

Adding to the usefulness of the book are the questions for class discussion at the end of each chapter and the bibliography and film bibliography at the end of the book. The illustrations are adequate but are not quite up to the general excellence of the text. The new edition should find wide acceptance among college teachers of hygiene.

Queries and Minor Notes

The answers here published have been prepared by competent authorities. They do not, however, represent the opinions of any official bodies unless specifically stated in the reply. Anonymous communications and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted on request.

PREVALENCE OF VENERIAL DISEASES

To the Editor:—Can you advise me, or can you refer me to publications containing statistics on the percentage of the total adult population in the United States who have or have had some form of venereal disease, together with breakdown of these figures, i. e., white persons and Negroes, males and females, age groups, forms of venereal disease, and percentages as to sections of the country as a whole. I should also like to know what the percentage of decline in the venereal disease rate is today as compared with the rate, say, of ten years ago.

George J. Korby, M.D., Detroit.

Answer.—The percentage of the total adult population in the United States who have or have had some form of venereal disease is not definitely known. Morbidity reports for the several venereal diseases are unreliable for a number of reasons, chief among which are (1) the fact that many people with venereal disease, particularly gonorrhea, do not seek treatment and (2) physicians in private practice often do not submit morbidity reports on venereal disease patients because of social implications.

The best estimate available on the prevalence of venereal disease is limited to syphilis. Studies of selectees during the mobilization period prior to World War II together with earlier studies of other groups by the Public Health Service give the best information available. Most of these studies were published during the years 1938 to 1942 in The Journal and in *Venereal Disease Information.* Depending on the geographic location, from 2 to 5 per cent of the adult population of the country have syphilis at any one time; the average would probably be about 3 per cent. Acquired syphilis occurs two to three times as often in men as in women and is about two to eight times as common in the Negro as in the white person. It is interesting that in the Negro the availability of free clinics seems to have a direct influence on prevalence. Syphilis is most frequently acquired by women between the ages of 16 and 20 and by men between the ages of 21 and 25. The higher prevalence of syphilis, according to these studies, is in the Southeastern states and the states along the Mexican border.

Because of the lack of information on the prevalence of venereal disease there is only limited information available regarding the decline in venereal disease rates. For further information on this subject reference is made to chapter 14 of the book "The Control of Venereal Disease" by R. A. Vonderlehr and J. R. Heller Jr. published by Reynal and Hitchcock, New York, 1946.

BLOOD CALCIUM DETIRMINATIONS

To the Editor:—My laboratory is having great difficulty in getting accurate results with our blood calcium determinations. We are using the method of Roe and Kahn (*J. Biol. Chem.* **81:** 1 [Jan.] 1929). It is both time consuming and inaccurate. I would appreciate it if you could advise me on any other photoelectric determination or any other means which would simplify our procedures. The other laboratories in town are having similar difficulties, and some are refusing to make blood calcium tests for this reason.

Albert I. Clark, M.D., Shreveport, La.

Answer.—Calcium determinations as performed in many clinical laboratories are not reliable, as any method requires the utmost care, with attention given to details of every step in the technic. A method that may be of interest to the inquirer is that of Sendroy (Sendroy, Julius, Jr.: Photoelectric Determination of Oxalic Acid and Calcium, and Its Application to Micro- and Ultramicroanalysis of Serum, *J. Biol. Chem.* **144:**243 [June] 1942). Calcium is directly precipitated as calcium oxalate and measured by the extent of its reduction of a constant amount of ceric sulfate. The author claims that the sensitive photoelectric technic of iodometry employed has an average error of ±2 per cent in the measurement of as little as 0.002 mg. of calcium or 0.02 mg. of serum.

In many laboratories the method that is still preferred is some modification of Tisdall's titration method, such as that of Clark and Collip (Clark, E. P., and Collip, J. B.: A Study of the Tisdall Method for the Determination of Blood Serum Calcium with a Suggested Modification, *ibid.,* **63:**461 [March] 1925).

PSORIASIS OF THE NAILS

To the Editor:—I should like an evaluation of the forms of treatment for psoriasis of the fingernails. A man aged 32 has had a moderately severe psoriatic involvement of the fingernails for six years. The condition has become worse in the past eighteen months, so that now there is a constant, ugly appearance to three or four nails owing to cutting away the dead portions of the nails plus removal of the detritus and, in conjunction with the discoloration, looseness and sponginess of the ungual wall over the nail root. Do you think that this pink spongy tissue over the nail root might promote rheumatoid arthritis by serving as a chronic source of mild infection? The patient is a professional man and must meet many people each day. Please discuss the advisability of removing the severely affected nails, scraping the nail beds and wearing artificial nails. This would be a nuisance but may become necessary. X-ray therapy has not been used and does not seem to me to be advisable.

M.D., California.

Answer.—The inquirer does not state whether the nails alone are involved or changes in the skin are present too. The diagnosis of psoriasis of the nails alone is often difficult to make with certainty. Other diseases must be considered. In acrodermatitis continua, changes in the skin begin near the nails and the latter may be involved early. There may be rheumatoid disorders of the small joints just as there may be in psoriasis, especially of the arthropathic variety. It is implied that in this patient there are rheumatoid symptoms. It is not necessary to assume that the pathologic tissue about the nail acts as a nidus for the dissemination of noxae to produce rheumatoid changes. There is no assurance that trimming away such tissue will contribute toward better, or in itself quicken, healing.

Psoriasis of the nails frequently resists all treatment, especially when they alone are involved. The simplest and most effective remedy is the use of x-rays. This form of physical therapy requires knowledge of its proper use, experience and utmost care to prevent harm. The method is most apt to improve the state of the periungual tissues. The use of reducing agents such as anthralin ointment and chrysarobin may be effective. They may be applied under finger cots. If the skin is involved too, it also must be treated. Attention only to the nails with neglect of psoriasis of the skin lead to poorer results and more frequent recurrences in those appendages. It is not advisable to resort to surgical methods until all others are exhausted. It is unusual to find that removal of the nails or scraping leads to any permanent improvement. Quick relapse is common.

UNILATERAL BREAST HYPERTROPHY

To the Editor:—I have a patient aged 14, one of whose breasts is developing much more rapidly than the other. There is nothing to suggest tumor formation. How common is such a condition? Is there any method of treatment? What prognosis can be given as to the eventual comparative size of the two breasts?

M.D., New York.

Answer.—Two separate conditions in early adolescence may be responsible for unequal development resulting in mammary asymmetry. The most common is known as "early ripening," or so-called adolescent mastitis. In this condition the hypersensitive breast develops earlier and to a greater degree than its fellow. Once regular menstruation is established and sexual maturity is reached, the overdeveloped breast usually regresses until the two breasts are approximately the same size. Early ripening is a relatively common condition and does not require treatment. The prognosis for eventual symmetry is good. A second cause of mammary asymmetry is unilateral virginal hypertrophy. This is a relative rare condition in which the larger breast grows until it reaches a giant or abnormal size, being twice or more the volume of the normal breast. There is no treatment for this unilateral virginal hypertrophy until the maximum size of growth has been reached. Then plastic operation is indicated to reduce the abnormality in size.

NERVE CRUSHING OPERATION FOR POLIOMYELITIC PARALYSIS

To the Editor.—I am inquiring about the Billig-von Harreveld treatment for residual paralysis. As I understand it this treatment is given at the St. Luke's and Children's Medical Center, Philadelphia. Would you write me the details of this treatment? Is the treatment given at the University of Virginia Medical School?

A. W. Graves V, M.D., Lacey Spring, Va.

Answer.—The Billig-van Harreveld procedure for treatment of infantile paralysis is a manual operation to interrupt the remaining intact motor nerve fibers of a paretic muscle. The success of such a procedure is based on the possibility that the interrupted nerve fibers will branch during regeneration, thereby providing an increased number of nerve fibers to innervate muscle cells.
